Status and Conservation. Not globally threatened. Fairly common to common from Mexico S; in Costa Rica uncommon and local in dry areas of NW and in C valley, common to abundant in some Pacific-slope valleys, in Nicoya Peninsula, and on Caribbean slope E to R Frío in N, and rare on Pacific slope S of Gulf of Nicoya. Status in Panama uncertain; sight records require confirmation, and specimens from the single published record cannot be located (the species remains unrecorded in adjacent SW Costa Rica). Occurs in a number of protected areas, including Palenque National Park, Selva el Ocote Special Biosphere Reserve and Calakmul and Punta Put Biosphere Reserves (Mexico), Tikal National Park (Guatemala), Crooked Tree Wildlife Sanctuary and Cockscomb Basin Forest Reserve (Belize), Capiro–Calentura National Park (Honduras) and Arenal National Park (Costa Rica). The species occurs widely also in unprotected areas, many of which consist of second-growth and disturbed habitat, but are at little immediate risk.

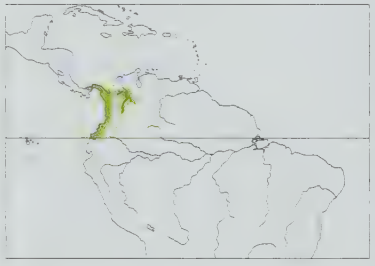
225. Green-chinned Euphonia

Euphonia chalybea

French: Organiste chalybée **German**: Bronzeorganist **Spanish**: Eufonia Bronceada
Other common names: Green-throated Euphonia

Taxonomy. *Tanagra chalybea* Mikan, 1825, Ypanema, São Paulo, Brazil.
Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. Monotypic.
Distribution. SE Brazil (from Rio de Janeiro S to C Rio Grande do Sul) and adjacent E Paraguay (Canindeyú S to Guairá and Itapuá) and NE Argentina (Misiones and Corrientes).



Descriptive notes. 11 cm; 18–20 g. Relatively large euphonia with noticeably thick bill. Male has small yellow frontal band, lores blackish; rest of head and upperparts, including upperwing-coverts, glossy dark greenish-blue; uppertail dark greenish blue, flight-feathers dusky, secondaries and tertials edged dark greenish-blue; chin and most of throat glossy dark greenish-blue, lower throat and rest of underparts bright yellow; undertail entirely dark dusky grey (no white); iris dark brown; bill bluish-grey with blackish tip; legs dark grey. Female is entirely olive above; side of head, side of neck and underparts mostly pale grey; chin, sides, flanks and undertail-coverts olive-yellow. Juvenile male resembles female. Voice. Call a short series, "chik chik chik chik chik", duration c. 1 second. Song a squeaky and raspy series of warbling notes, varying from moderate to high in pitch, delivered rapidly and generally without any mimicry.
Habitat. Primarily humid forest, wooded borders, tall second growth, and clearings with large trees. Lowlands to c. 900 m.
Food and Feeding. Fruits; also, insects, including caterpillars, and spiders (Araneae). Reported to favour epiphytic fruits, including those of *Rhipsalis* cactus; pokeweed berries (*Phytolacca*) and fruits of *Abutilon* also recorded. Found in pairs and in small monospecific groups; regularly with mixed-species flocks containing other tanagers and other birds along forest borders, and occurs also with feeding groups at fruiting trees. Stays mostly well up in trees. Searches branches for small food items. Otherwise, not especially well known.
Breeding. Breeding recorded in Oct in Brazil (Paraná). Nest a rounded structure of plant stems and leaves with side entrance, much as those of congeners; one nest in Brazil was placed among epiphytes c. 15 m up on large branch, one in Paraguay among orchids and epiphytes on limb near a house. Eggs believed to have been of this species were yellowish with red-brown spots. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Fairly common locally in SE Brazil Atlantic Forests from Rio de Janeiro S to Rio Grande do Sul. In E Paraguay recently found in Canindeyú, Alto Paraná, Caazapá, and Itapuá; and in NE Argentina recent records from Misiones and Corrientes. Much of area in which it lives is heavily deforested, and this species is believed to be declining. Occurs in numerous parks and other reserves, including Iguazú National Park (Argentina) and Iguaçu, Itatiaia and Serra da Bocaina National Parks (Brazil). Because of high rates of deforestation, unprotected forest and woodland sites remaining within this species' range are likely to be at risk in the near term.
Bibliography. Anon. (2010a), Belton (1985), Bertoni (1901), Butchart & Stattersfield (2004), Descourtilz (1852), Isler & Isler (1999), Narosky & Di Giacomo (1993), Nehrkorn (1899), Parker & Goerck (1997), de la Peña & Rumboll (1998), Ridgely & Tudor (1989, 2009), Sick (1985, 1993), Souza (2002), Stattersfield & Capper (2000), Voss & Sander (1981).

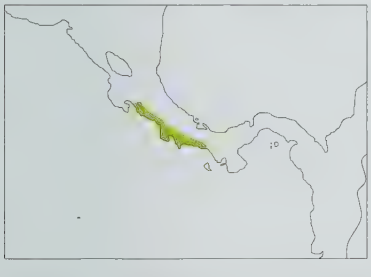
226. Fulvous-vented Euphonia

Euphonia fulvicrissa

French: Organiste cul-roux **German**: Roststeißorganist **Spanish**: Eufonia Ventricanela

Taxonomy. *Euphonia fulvicrissa* P. L. Sclater, 1857, Santa Marta, Colombia; probably error = locality undetermined.
Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. This species has been considered to form a superspecies with *E. imitans*. Three subspecies recognized.
Subspecies and Distribution.
E. f. fulvicrissa P. L. Sclater, 1857 – C Panama (from Coclé and Colon on Caribbean side and Panamá on Pacific side) E to W Colombia (N Chocó).
E. f. omissa E. J. O. Hartert, 1913 – N base of Colombian Andes from Antioquia E to NW end of E Andes in Norte de Santander (including Sinú Valley, lower Cauca Valley and middle Magdalena Valley) and Pacific coast S to Cauca.
E. f. purpurascens E. J. O. Hartert, 1901 – SW Colombia (Nariño) S to NW Ecuador (Esmeraldas, Manabí and NW Pichincha).

Descriptive notes. 9 cm; 10·1–13 g. Rather small euphonia with tawny-rufous undertail-coverts. Male nominate race has small lemon-yellow patch on forehead extending back to just above eye; rest of head, throat to central chest and upperparts, including upperwing-coverts, glossy blue-black; flight-feathers dusky, tinged blue black; uppertail blue-black with slight gloss; breast, sides and flanks bright golden-yellow, median underparts cinnamon-yellow, vent and undertail-coverts yellowish-cinnamon; undertail dark grey, inner webs of outer two feather pairs mostly white, forming large, somewhat oval-shaped white patch on each side; iris dark brown; upper mandible and tip of lower mandible dusky blackish, rest of lower mandible blue-grey; legs dark grey. Female has small rufous patch on forecrown; hindcrown, nape and upper back bronzy olive-green with faint greyish gloss, lower back, rump and tail yellowish-olive; flight-feathers dusky, edged olive-yellow; underparts olive-yellow, brightest on sides; centre of belly and undertail-coverts contrastingly tawny-rufous. Juvenile apparently undescribed. Race *omissa* differs from nominate in having white ovals on underside of tail less extensive; *purpurascens* differs in having upperparts and uppertail with purplish gloss, no white on undertail. Voice. Commonest call a chattery rattle, "d'e'e'e'h, d'e'e'e'h", occasionally a single "d'e'e'e'h" or up to three rattles in a row (in Panama, "Ren-ren" an onomatopoeic local name for species based on this call). Also gives a rising whistle,



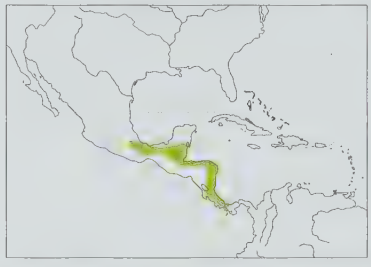
"wheet", and doubled "wheet-wheet", sometimes every few seconds. Song, in Colombia, consists of 1–3 soft, chattery rattles followed by 1–2 short, complex and squeaky phrases that rise in pitch, e.g. "du, d'u'u'u-d'u'u'u spze'e't'tic, spze'e't'tic...du'u, d'u'u'u-d'u'u'u spze'e't'tic..." and so on, continuing for up to a minute or more.
Habitat. Humid and wet forest, forest borders, and shrubby or overgrown clearings and second-growth woodland. In Panama occurs in humid lowland and foothill sites, in decreasing numbers to c. 900 m; in Colombia up to 1000 m (most records below 500 m).
Food and Feeding. Typically feeds on small fruits, less than 5 mm in diameter; also reported as taking arthropods. In Panama, known to eat catkins of *Piper* and *Cecropia* and fruits of *Lantana*, *Hamelia*, mistletoe (Loranthaceae), and *Lindackeria*. Occurs singly, in pairs and in small groups, and is regularly associated with mixed-species flocks. Commonly forages in upper levels of trees, but also regularly decends much lower to shrubs and small fruiting trees along forest borders and in clearings. On Barro Colorado (Panama), most records of foraging were at 10–25 m above ground level.
Breeding. In Colombia, 13 birds in breeding condition in Jan–Jul in N and two others in Apr in Antioquia. Covered nest with side entrance, like that of congeners; male and female building nest of fibrous material in thick hanging moss 12 m up in tree. No other information.
Movements. Resident. Minor elevational movement (seasonal or wandering individuals) possible, but documentation required.
Status and Conservation. Not globally threatened. Fairly common to common over most of range. Occurs in numerous protected areas, including Metropolitan, Soberanía, Chagres and Darién National Parks (Panama) and Los Katíos, Tatamá and Utría National Parks and privately held Reserva Natural El Paujíl (Colombia); possibly in Sanquianga National Park, in SW Colombia. This species occurs also in a variety of second-growth and forest-edge habitats, much of which, though unprotected, is likely to persist at least for the short term, despite ongoing forest clearance.
Bibliography. Davis (1972), Greenberg (1981a), Haffer (1975), Hilty (1997), Hilty & Brown (1986), Isler & Isler (1999), Jahn *et al.* (2002), Leck (1971b), Lovette & Bermingham (2002), Moynihan (1962c), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Stiles *et al.* (1999), Wetmore *et al.* (1984), Willis (1980), Willis & Eisenmann (1979).

227. Spot-crowned Euphonia

Euphonia imitans

French: Organiste moucheté **German**: Stirnfleckenorganist **Spanish**: Eufonia Coronipinta
Other common names: Tawny-bellied/Tawny-tailed Euphonia

Taxonomy. *Tanagra imitans* Hellmayr, 1936, El Pózo, River Térraba, Costa Rica.
Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. This species has been thought to form a superspecies with *E. fulvicrissa*. Monotypic.
Distribution. Pacific slope of Costa Rica (from at least Carara and San José) S to W Panama (Chiriquí).



Descriptive notes. 10 cm; 14 g. Small euphonia with stubby bill. Male has bright yellow forehead patch extending back to rear edge of eye, yellow inconspicuously dotted with black (especially near mid-crown) and with a few weakly indicated hair-like black streaks; rest of head, throat, chest, side of neck, and upperparts steely blue-black; upperwing-coverts slightly glossed blue-black, flight-feathers and tail dusky with dark blue-black tinge, flight-feathers with white bases to inner webs of all but outermost two feathers; side of chest and lower breast to undertail-coverts bright yellow, underwing-coverts white; iris dark brown; bill blackish, basal half of lower mandible pale blue-grey; legs dark grey. Distinguished from similar *E. luteicapilla* mainly by thicker bill and much more restricted yellow crown patch (black forecrown dots difficult to see). Female has contrasting rufous-chestnut forehead; otherwise dark olive-green above, greyish-blue tinge on crown and nape and slight blue-grey tinge extending across back, uppertail-coverts slightly yellowish; upperwing-coverts and flight-feathers dusky, broadly edged yellowish-olive; mainly olive-yellow below, paler on throat, and with sharply contrasting tawny-rufous centre of lower breast, belly and undertail-coverts. Juvenile is like female, but duller, and without rufous colour. Voice. Calls include a rolling or rattled "tr'r'r'r'r" or "chu'r'r'r'r", most often doubled or given in a series of 3–4, all with metallic quality and very similar to call of *E. fulvicrissa*; rattles may be preceded by one or two descending, slurred whistles, "twerp". Also gives a sibilant "yerrlirr", and scolds with harsh, rolling "jurry-jurry". Song typically consists of a note or phrase repeated 5–8 times, followed by abrupt shift to another series; some songs are clear sweet warbles, others chaffy or wheezy and dry, e.g. "chip a cheer weet; chip tuck tuck; wee churee-cha...", and so on, sometimes continued for up to 30 minutes.
Habitat. Humid forest and adjacent forest borders, shady clearings and tall second growth. Lowlands and foothills to c. 1350 m.
Food and Feeding. Mainly small berries, also some larger fruits, nectar; also insects. Found mainly alone or in pairs, infrequently in groups of three or more individuals; regularly associated with mixed-species flocks. Forages from low to high levels, most often at middle strata or higher. Noted as eating bits of banana from feeders. Mashes small berries to discard skin, and pecks holes in or pieces from larger soft-bodied fruit. Searches mossy branches and tangles of dead leaves for insects. Observed to roost alone in little pockets of moss or in epiphytes on branches.
Breeding. Breeding recorded in Mar–Jun in Costa Rica; two broods may be attempted. In Costa Rica, both male and female seen building nest, a rounded or domed structure similar to that of congeners, side entrance may be covered by small overhanging porch, made from green moss, rootlets and ferns, lined with narrow strips of bark and/or fine vegetable fibres, and often placed in suspended tangle of epiphytes or in hanging branch; eight nests were 2–7·5 m above ground, two others were sited over a stream. Clutch 2–3 eggs, usually 2, white or pinkish-white, sparingly marked with brown, more heavily at larger end; incubation by female alone, period for one clutch was 18 days.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in South Central American Pacific Slope EBA. Uncommon to locally common in SW Costa Rica, numbers rapidly diminishing N to Carara; rare to locally uncommon in adjacent SW Panama. Few or no recent records in W Panama lowlands, which has been subject to severe deforestation; small numbers survive in forest fragments at higher elevations. Occurs in a few protected areas in Costa Rica, including Corcovado, Manuel Antonio and probably Carara National Parks, and the Wilson Botanical Garden (near San Vito). Although this species is not currently considered threatened, much of the native forest within its range has been destroyed and its now fragmented populations are in urgent need of monitoring.
Bibliography. Davis (1972), Eisenmann (1955), Garrigues & Dean (2007), Isler & Isler (1999), Ridgely & Gwynne (1989), Skutch (1972), Slud (1964), Stiles & Skutch (1989), Wetmore *et al.* (1984).

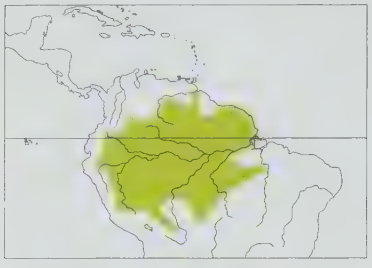
228. Olive-backed Euphonia

Euphonia gouldi

French: Organiste olive **German**: Olivrückenorganist **Spanish**: Eufonia Olivácea
Other common names: Gould's Euphonia

Taxonomy. *Euphonia Gouldi* P. L. Sclater, 1857, Guatemala.
Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. Proposed race *loetscheri* (described from Dos Amates, NE of Catemaco, in Veracruz) considered inseparable from nominate. Two subspecies recognized.
Subspecies and Distribution.
E. g. gouldi P. L. Sclater, 1857 – Gulf–Caribbean slope of Mexico (S Veracruz E to S Quintana Roo, S to N Oaxaca and N Chiapas) S through N Guatemala and Belize to Honduras.
E. g. praetermissa (J. L. Peters, 1929) – extreme SE Honduras, E Nicaragua, E Costa Rica (locally also on Pacific slope in Guanacaste) and NW Panama (NW Veraguas).

Descriptive notes. 9–10 cm; 10·9–16 g. Small euphonia with thick and stubby bill, both sexes with drab female-type plumage. Male nominate race has yellow on forehead extending back to top of eye, sometimes with light black flecks; rest of head and upperparts, including tail, olive-green with bluish-grey gloss, uppertail-coverts plain olive-green (no gloss); upperwing-coverts bronzy olive-green, primary coverts black, flight-feathers dusky, sharply edged greenish-yellow; face, throat and chest olive, sides and flanks irregularly mottled yellow and olive, lower breast, belly and undertail-coverts contrastingly tawny-rufous; some individuals (not all) have minor amount of white on inner webs of outer two tail feathers (visible from below as white oval on each side of tail); iris dark brown; bill blackish, basal half of lower mandible blue-grey; legs dark grey. Female differs most obviously from male in having forehead dark rufous (not yellow), rest of upperparts olive with slight grey tinge (not glossy); yellowish-olive below, sides and flanks darker olive, vent and undertail-coverts dark rufous. Female differs from very similar female of *E. imitans* in having duller forecrown less sharply defined along rear edge, often a diffuse dusky supraloral line, more olive-green (less grey) nape and back, and absence of rufous on most of belly. Juvenile is much like adult of respective sex, but tinged dusky on crown and nape; older birds (presumed immature) show some yellow (male) or rufous (female) on forecrown while still duller than adult; adult plumage acquired within a few months of age. Race *praetermissa* is similar to nominate, but differs in decidedly smaller size (wing 52–56 mm; nominate 55–60 mm), and, on average, less extensive chestnut in abdominal area. Voice. Commonest calls are a rolling "churrr-churrr" or "chur-chur-chur" with metallic quality, and rougher "dee-dee-dee" with throaty or burred quality; lacks clear whistled "beem beem" calls typical of "black-and-yellow" euphonias. Song, from high, partly open perch (as bird wags or twitches tail from side to side), a rambling medley of whistles, chatters and staccato notes, some dry and chaffy, some musical, often sustained for long periods of time.
Habitat. Tall humid and wet lowland and foothill forest, and tall second growth and shady clearings adjacent to or within rainforest. Mainly sea-level up to c. 500 m; recorded up to 1200 m in Guatemala.
Food and Feeding. Known to eat wide variety of small berries, including *Anthurium* (Araceae), *Miconia* and other melastomes, *Trema* (Cannabaceae), *Urera* (Urticaceae), mistletoes (Loranthaceae), and catkins of *Cecropia*. Four stomachs contained small-seeded fruits. Captives show distinct preferences based on ripeness, accessibility and fruit type. Occurs singly and in pairs, somewhat less often in little groups; regularly with mixed-species flocks. Stays mainly in canopy, but occasionally descends to middle levels. Most fruit taken while bird perched, rarely while in flight. Swallows fruits whole, or mashes them and discards skin, and sometimes also seed, before swallowing pulp.
Breeding. Breeding reported in May in Belize and Feb–Jul in Costa Rica. Nest a globular structure with side entrance, made from thin roots, rhizomes, green moss, and fine palm and other fibres, lined with fine grasses or other fibres, placed 2–15 m up in clump of moss or epiphyte or built within suspended vegetation on hanging branches, vines or rootlets. Clutch 2–4 eggs, usually 3, dull white with brown spots and blotches, mostly in wreath at larger end. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to locally common. A Caribbean lowland species, population now much reduced by loss of rainforest in region. Occurs in a number of protected areas, including Palenque National Park (Mexico), Tikal National Park (Guatemala), Crooked Tree Wildlife Sanctuary, Caracol Archaeological Reserve, Cockscomb Basin Forest Reserve and Chan Chich Nature Reserve (Belize), Capiro–Calentura National Park (Honduras), Indio-Maíz Biological Reserve (Nicaragua), La Selva Biological Station (Costa Riva) and Bastimentos National Park (Panama). The species' range formerly included much forest outside protected areas, but few large areas of suitable lowland forest now remain, except in N Guatemala and E Nicaragua.
Bibliography. Carriker (1910), Davis (1972), Edwards (1972), Eisenmann (1955), Garrigues & Dean (2007), Hanson (2008), Howell, S.N.G. & Webb (1995), Howell, T.R. (1957), Isler & Isler (1999), Land (1970), Moermond & Denslow (1985), Monroe (1968), Ridgely & Gwynne (1989), Ross & Whitney (1995), Russell (1964), Slud (1964), Smithe (1966), Stiles & Skutch (1989), Strauch (1977), Tashian (1952), Wetmore *et al.* (1984).



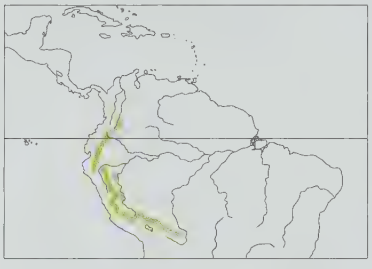
229. White-lored Euphonia

Euphonia chrysopasta

French: Organiste fardé **German**: Zügelorganist **Spanish**: Eufonia Maquillada
Other common names: Golden-bellied Euphonia

Taxonomy. *Euphonia chrysopasta* P. L. Sclater and Salvin, 1869, lower Ucayali, Peru.
Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. Two subspecies recognized.

Subspecies and Distribution.
E. c. nitida (T. E. Penard, 1923) – extreme E Colombia (along R Orinoco), S Venezuela (S of Orinoco) E to French Guiana, and N Brazil N of R Amazon.
E. c. chrysopasta P. L. Sclater & Salvin, 1869 – SE Colombia (from Meta) S through E Ecuador and E Peru to N Bolivia, and W & C Brazil (E to R Xingu and, in E Pará, to R Tocantins).



Descriptive notes. 9–10 cm; 11–16·2 g. Small, comparatively plain euphonia, male with female-type plumage, bill noticeably thick and with cutting edges not quite straight (like slightly crooked grin). Male nominate race has base of forehead to chin and cheeks ashy whitish-grey, forming fairly conspicuous oval-shaped area of white surrounding bill (like a "milk moustache"); forecrown olive, with narrow dusky border at front, rest of crown and nape greyish; upperparts, including upperwing-coverts, olive-green with bluish-grey gloss, uppertail-coverts paler; uppertail olive; flight-feathers dusky, edged and tinged olive-green; mostly yellow below, slight olive tinge on sides and becoming clear yellow on centre of belly and undertail-coverts; undertail plain greyish (no white); iris dark brown; bill blackish, basal half or more of lower mandible greyish; legs horn-grey. Female is much like male above, but considerably duller, with whitish around bill less extensive, side of head yellowish-olive; mostly grey below, with sides, flanks and undertail-coverts olive-yellow. Juvenile apparently undescribed. Race *nitida* is slightly smaller than nominate, male having less grey on crown and nape, slightly duller underparts. Voice. Calls include variety of smacking notes and short whistles; one of commonest calls a rather loud buzzy "spitz wéet!" repeated over and over, and a sharp, smacking "spitz!". Lacks clear whistled calls of "black-and-yellow" euphonias. Male's song, often from high bare twig in open (may nervously twitch or wag tail to one side, sometimes accompanied by bobbing of entire rear body up and down as it sings) a jumble of "chit, sit, spitz, week" and other notes, sputtering on in fits and starts, sometimes for several minutes, with pauses of varying length, e.g. "p-pfits'et cheéu...sit, fits...pa'fits-a-whew!...", and so on. Some songs appear to be patterned, others more random in choice of notes and phrases.
Habitat. Canopy of humid *terra firme* and *várzea* forest, tree-scattered shady clearings, forest borders and tall second-growth woodland. Lowlands to c. 1000 m, occasionally to 1300 m.
Food and Feeding. Fruits and insects. One stomach contained only seeds. Usually seen in pairs, less often singly or in small groups of up to about six individuals; at times joins mixed-species flocks. Forages in clumps of mistletoe (Loranthaceae) high in forest canopy or in fruiting trees, where sometimes with other members of genus; typically stays high up and searches for insects by foraging on long slender bare twigs, sometimes going out to tip. Occasionally descends low along forest borders and in clearings with trees when visiting fruiting shrubs and other small trees.
Breeding. Breeding reported in Aug in Ecuador, and numerous records in Aug and Sept in SE Peru. Nest built by both sexes, covered and football-shaped, with side entrance, made from various grassy material, moss, bits of leaves and ferns, even dry leaves, placed 5–35 m or more above ground (most often quite high) in crevice, or hidden in epiphytes, moss and ferns on side of large limb in canopy, sometimes on side of spiny palm trunk. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Common and widespread across Amazonia. Occurs in a number of large protected areas, including Tinigua, Serranía de Chiribiquete, La Paya, Cahuinarí and Amacayacú National Parks (Colombia), Yasuní National Park and Cuyabeno Wildlife Reserve (Ecuador), Alto Purús and Manu National Parks and Pacaya-Samiria National Reserve (Peru), Madidi National Park (Bolivia) and Serra do Divisor, Jaú and Amazonica National Parks (Brazil). The species' range also includes extensive intact habitat which, though unprotected, is at little near-term risk.
Bibliography. Dick *et al.* (1984), Dunning (1982), Gyldenstolpe (1945b), Hellmayr (1910), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1966, 1970a), Meyer de Schauensee & Phelps (1978), Naumburg (1930), O'Neill (1974), Pearson (1975c), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg (2000c), Schulenberg *et al.* (2007), Sick (1985, 1993), Snethlage (1914), Snyder (1966), Souza (2002), Tostain *et al.* (1992), Willis (1977), Zimmer (1943a).

230. **Bronze-green Euphonia**

Euphonia mesochrysa

French: Organiste mordoré **German**: Grünscheitelorganist **Spanish**: Eufonia Verdosa

Taxonomy. *Euphonia mesochrysa* Salvadori, 1873, no locality = Bogotá.
Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. Three subspecies recognized.
Subspecies and Distribution.
E. m. mesochrysa Salvadori, 1873 – Colombia (at head of Magdalena Valley in Huila; E slope of E Andes from E Cundinamarca and W Meta) S to E Ecuador (Napo and Morona-Santiago).
E. m. media (J. T. Zimmer, 1943) – N & C Peru on E slope of Andes (Amazonas and Cajamarca) S to Cuzco (R Chanchamayo).
E. m. tavarae (Chapman, 1925) – SE Peru (S from R Tavara) S on E slope of Andes to Bolivia (to Cochabamba and extreme W Santa Cruz).

Descriptive notes. 9–10 cm; 12–15 g. Small and rather drab euphonia with thick and stubby bill. Male nominate race has narrow dark olive band (inconspicuous) over bill, bordered above on forehead by bright yellow patch; mid-crown olive, rear crown greyish fading to olive on nape; upperparts olive with strong grey-blue gloss, uppertail dusky olive; upperwing-coverts olive-green, primary coverts blackish, flight-feathers dusky, outer ones edged yellow-green, inner feathers and tertials progressively more broadly edged olive-green; throat, chest and sides yellowish-olive; rest of underparts deep ochre-yellow; tail entirely dark grey below (no white); iris dark brown; bill blackish above, most of lower mandible bluish-grey; legs dark grey. Female is like male above, but entire forecrown to mid-crown olive (no yellow), and rear crown and nape strongly tinged greyish; throat, chest and upper breast duller olive-yellow, centre of lower breast and belly light grey, sides, flanks and undertail-coverts dull olive-yellow. Juvenile undescribed. Race *media* is much like nominate, male differing in darker coloration, yellow of forehead wider and darker, back of head darker grey, olive of back darker, olive of throat also darker and more restricted, and yellow of underparts darker and more extensive, female also darker than nominate female; *tavarae* male differs from nominate in numerous subtle ways, including slightly paler forehead, dark band at base of forehead wider, throat darker and more olive and contrasting more with yellow of belly, which is less orange-tinted. Voice. Rather quiet; lacks loud whistles of "black-and-yellow" euphonias, and all vocalizations somewhat ventriloquial. Call a soft burry "tr-r-r-r-r", sometimes doubled or tripled, or notes may be shorter, e.g. "tr-r-r tr-r-r"; also utters weak high "chip" note, this also sometimes doubled or given in longer series. Song 1–3 low whistled notes followed by a series of low burry trills, "whut tr-t-t tr-t-t tr-r-r" or "whu-téé-wur-pur'r'r't"; song sometimes accompanied by "chip" notes.
Habitat. Humid and wet montane forest (cloudforest). Occurs in steep hillside forest and along forest borders, and visits small trees and shrubs in clearings and landslides and along roadsides. Recorded mainly at 800–2150 m, less often down to c. 600 m in foothills; in Ecuador 1100–1800 m, locally to 900 m; in Peru mainly 1000–2000 m, locally down to 450 m (in Puno); one record in NE Peru (Loreto) at 150 m.
Food and Feeding. Fruits and berries; probably some insects. Apparently feeds mainly on berries of smaller trees and shrubs with low but prolonged fruiting periods, e.g. melastomes and *Cecropia*. Two stomachs contained only fruit. Rather quiet and timid, most often seen when it comes to feed on berries at small forest-edge melastome shrubs or other small fruiting trees, either with temporary feeding associations or with mixed-species flocks containing *Tangara*, *Chlorospingus* and other small tanagers; frequently follows mixed flocks. In Peru reported as searching small clumps of moss, lichens and epiphytes on branches and large limbs, occasionally on tree trunks, and frequently seen in mistletoe.
Breeding. No information.
Movements. Little information. Some seasonal or irregular elevational movement in response to changing resource levels likely.
Status and Conservation. Not globally threatened. Uncommon. Can be found in a number of protected areas on E Andean slope, including Cordillera Los Picachos National Park (Colombia), Sangay National Park (Ecuador), Manu National Park (Peru) and Madidi National Park (Bolivia). Although E slope of Andes has suffered extensive deforestation, wide areas of unprotected intact habitat remain which unlikely to be at risk in the near term.

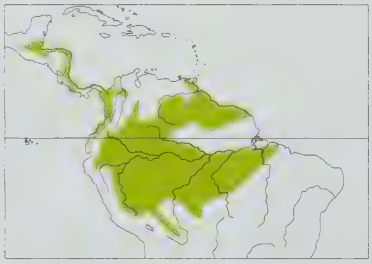
PLATE 27 ➤

231. White-vented Euphonia

Euphonia minuta

French: Organiste cul-blanc **German**: Weißbauchorganist **Spanish**: Eufonia Culiblanca



Taxonomy. *E.[uphona] minuta* Cabanis, 1848, Guyana.

Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. The two races are so similar that species may be better treated as monotypic. Two subspecies tentatively recognized.

Subspecies and Distribution.

E. m. humilis (Cabanis, 1861) – extreme SE Mexico (Palenque, in Chiapas) very locally E to C Guatemala and S Belize and N Honduras, and S on Caribbean slope from E Nicaragua to Panama, and on Pacific slope from SW Costa Rica E to Panama (Veraguas), N base of Andes in Colombia (E to C Magdalena Valley) and S on entire Pacific coast to NW Ecuador (to S Pichincha).

E. m. minuta Cabanis, 1848 – E base of Venezuelan Andes (in Táchira) and SE Colombia (from Meta and Vaupés) S through Ecuador and Peru to C Bolivia (Santa Cruz), and generally E across S & E Venezuela, the Guianas, and Amazonian Brazil (E to mouth of R Amazon, and S to S Amazonas and C Pará; once in E Mato Grosso).

Descriptive notes. 9 cm; 7·9–11·5 g. Very small, compact euphonia with distinctive white undertail-coverts, and short, thick bill. Male nominate race has small bright yellow patch on forehead (not extending back to eye); rest of head down to foreneck, and upperparts, including uppertail and upperwing-coverts, glossy blue-black, head and nape glossed purplish; flight-feathers dusky, edged dark blue; breast and belly bright yellow, sometimes with a little dusky mottling on flanks; middle belly and undertail-coverts white, underwing-coverts white; inner webs of outer three pairs of tail feathers white (forming large oval-shaped white patch on each side of undersurface); iris dark brown; bill black, basal two-

thirds of lower mandible blue-grey; legs dark grey. Female has head and upperparts, including wings and tail, olive; throat dingy greyish-white, chest, upper breast, sides and flanks olive-yellow, centre of lower breast, belly and undertail-coverts white (appearance of broad diffuse breastband). Juvenile resembles female, but duller. Race *humilis* male differs from nominate in having yellow forehead patch larger, and chest and upper breast slightly darker, richer yellow. Voice. One of commonest calls is a sharp "veet", also a sputtery "wee-chu". Song surprisingly loud and forceful for so small a bird, a shrill series of sharp and staccato notes, "tu, véévéét, ch-véét, cheewit, chewit, ...véét...ch-véét, tsik, veéé, vic-squik, squik-squik, veéé..." and so on; louder "véét" and "veéé" notes are characteristic of almost all songs, even though song patterns may vary. Both sexes call frequently when nest-building.

Habitat. Humid and wet lowland tropical forest, along forest borders, less frequently in canopy of large trees in clearings adjacent to tall forest. Most numerous in lowlands up to c. 500 m, although recorded to 1500 m in Costa Rica; to 1000 m locally in Colombia, 700 m in W Ecuador and c. 1000 m in Peru.

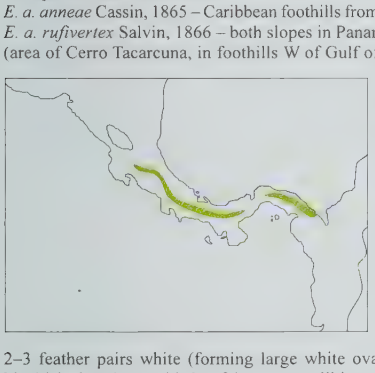
Food and Feeding. Feeds heavily on mistletoe berries (Loranthaceae); also small fruits, and insects. Seen singly, in pairs, and sometimes in varying-sized groups that may be composed mostly of males or female-plumaged birds, groups tending to wander over large areas and usually staying in forest canopy. Spends long periods of time in or near clumps of mistletoe, sometimes in association with other members of genus; also regularly follows mixed-species flocks in canopy, where it takes small fruits and searches for insects by hopping or sidling along, or executing "about-face" turns as it hops, especially, along bare, thin twigs, mostly on outer branches. Has habit of frequently wagging partly spread tail to one side.

Breeding. Breeding reported in Feb–Jul in Costa Rica; two broods sometimes attempted. Nest much like that of congeners, globular with small circular side entrance, composed mostly of green moss, small ferns and orchid roots, lined with fine, pale-coloured plant fibres, located 3–18 m up amid mosses and other epiphytes on large branch of canopy tree. Clutch 3–5 eggs, white, heavily spotted and blotched with brown. No other information.

Movements. Mainly resident. Some early wet-season (Jun) wandering to higher elevations reported in Costa Rica; in W Colombia, upslope movement (to 1050 m) in R Anchicayá Valley in Jun–Aug.

Status and Conservation. Not globally threatened. Widespread and fairly common across Amazonia; local and uncommon in N of range (Central America), e.g. scarce and often irregular in Panama. Populations (mainly Caribbean) in Central America and on Pacific slope in SW Costa Rica and adjacent SW Panama much less numerous and now local, e.g. there appear to be no recent lowland records from heavily deforested lowlands of W Panama; elsewhere in Panama the species is scarce and often irregular in occurrence. Extensive deforestation in portions of NW Colombia suggest that populations there are now fragmented and in decline, and all populations W of Andes are worthy of investigation. Found in numerous protected areas in Amazonia, and faces no serious threats in this region.

Anderson *et al.* (1998), Carriker (1910), Clark (1913b), Davis (1972), Dunning (1982), Eisenmann (1955), Fry (1970), Garrigues & Dean (2007), Haverschmidt & Mees (1994), Hilty (1997, 2003), Hilty & Brown (1986), Howell & Webb (1995), Isler & Isler (1999), Jahn *et al.* (2002), Land (1970), Pinto (1944b), Remsen (1976), Remsen *et al.* (1987), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg (2000c), Schulenberg *et al.* (2007), Sick (1985, 1993), Skutch (1972, 1976), Slud (1964), Snyder (1966), Souza (2002), Stiles & Skutch (1989), Strauch (1977), Willis (1977, 1980), Zimmer (1943a).



232. Tawny-capped Euphonia

Euphonia anneae

French: Organiste à couronne rousse **Spanish**: Eufonia Coronirrufa
German: Braunscheitelorganist

Taxonomy. *Euphonia Anneae* Cassin, 1865, Santa Rosa, Costa Rica.
Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. May form a superspecies with *E. xanthogaster*. Two subspecies recognized.

Subspecies and Distribution.
E. a. anneae Cassin, 1865 – Caribbean foothills from Costa Rica E to W Panama (Volcán de Chiriquí).
E. a. rufivertex Salvin, 1866 – both slopes in Panama (from Veraguas) E to extreme NW Colombia (area of Cerro Tacarcuna, in foothills W of Gulf of Urabá).

Descriptive notes. 11 cm; three birds from Panama 14·4–15·4 g (mean 14·9 g). Relatively small euphonia with thick bill. Male nominate race has most of crown rich rufous-chestnut, rest of head down to foreneck, and upperparts, including upperwing-coverts, glossy blue-black, nape, back, shoulders and wing-coverts strongly glossed purplish; flight-feathers dusky, edged dark blue, basal half of inner webs of most flight-feathers white, uppertail dark blue-black; breast to most of belly rich yellow, centre of rearmost belly and undertail-coverts white, underwing-coverts white; underside of tail dark grey, middle half of inner webs of outer 2–3 feather pairs white (forming large white oval on each side of tail); iris brown; bill dusky blackish, basal two-thirds of lower mandible greyish; legs horn-grey. Female has forecrown contrastingly dull rufous fading to grey nape and olive sides of crown; upperparts, including wing-coverts, olive-green, primary coverts duskier, flight-feathers and tail dusky, edged olive-yellow; chin, side of head and side of throat yellowish, tinged olive, centre of throat, breast and belly grey to greyish-white, becoming bright olive-yellow on sides, yellowish on flanks, and buff to ochre on belly and undertail-coverts. Immature is much like female, but duller. Race *rufivertex* male is very similar to nominate, but slightly smaller, and underparts, especially centre of chest, more orange-tinged, female very like nominate, but deeper grey underparts and less yellowish on flanks. Voice. Pair-members continually utter a thin, sharp "chip" when attending nest. Long, sustained song typically a note or phrase repeated 2–4 times before changing, e.g. "whee whee whee, wheer wheer, nah-a-a-ak, nah-a-a-ak, eeeenk eeenk eeenk, seeet seeet..." and so on, some phrases sputtering, others perhaps imitative; lacks metallic rolling or trilled notes prominent in songs of *E. imitans* and *E. gouldi*; also lacks the loud whistled notes of many of the "black-and-yellow" euphonias.

Habitat. Mainly dense humid and wet pre-montane and montane forest (cloudforest), forest borders, tall second-growth woodland, treefall gaps, and crowns of small to large trees in clearings. Mostly 600–1700 m in N half of Caribbean slope of Costa Rica; 900–2000 m in S half of Caribbean slope. Outside breeding season may wander to as low as c. 300 m; extreme records at 50 m and 2100 m likely to refer to vagrants or wanderers.

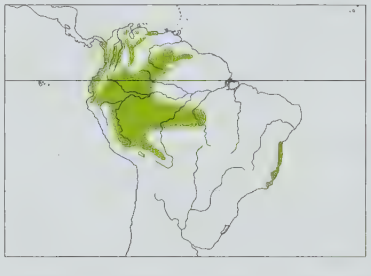
Food and Feeding. Mainly small berries, including mistletoe (Loranthaceae), various species of melastome, figs (*Ficus*), Ericaceae, and especially *Anthurium*; also insects. Often mashes berries and discards skins before swallowing pulp. Found in pairs and small groups, occasionally singly, and often with mixed-species flocks containing *Tangara* tanagers. Forages mainly in canopy and higher levels of forest, sometimes lower along forest borders and gaps. Spends a small amount of time in searching surface of small, high, bare twigs for insects.

Breeding. Season reported as Mar–Jun in Costa Rica; a laying female in Mar in Panama. Nest a globular structure with small side entrance much like that of congeners, composed of mosses and fibres, usually placed in cranny on epiphyte-laden branch or in moss on hanging vine, or similar site; nests recorded 8–11 m up at forest edge. No other information.

Movements. Mainly resident. Some seasonal movements to higher or lower elevations outside breeding season.

Status and Conservation. Not globally threatened. Restricted-range species: present in Central American Caribbean Slope EBA and Darién Lowlands EBA. Common in Costa Rica; apparently local and less numerous in Panama. Occurs in a few protected areas, among them Braulio Carillo and Tapantí National Parks (Costa Rica), Santa Fé, Soberanía, Chagres and Darién National Parks (Panama) and Los Katíos National Park (Colombia). Although deforestation within its range is extensive and ongoing, some large tracts of intact forest remain locally, although unprotected, these are likely to provide a buffer against near-term risk.

Bibliography. Carriker (1910), Davis (1972), Eisenmann (1955), Garrigues & Dean (2007), Haffer (1975), Hilty & Brown (1986), Isler & Isler (1999), Restall *et al.* (2006), Ridgely & Gwynne (1989), Ross & Whitney (1995), Salaman *et al.* (2008), Slud (1964), Stiles & Skutch (1989), Strauch (1977), Wetmore *et al.* (1984), Wolfe *et al.* (2009).



233. Orange-bellied Euphonia

Euphonia xanthogaster

French: Organiste à ventre orange **German**: Gelbbauchorganist **Spanish**: Eufonia Ventrinaranja
Other common names: Black-throated Euphonia ("*E. vittata*")

Taxonomy. *E.* [*uphone*] *xanthogaster* Sundevall, 1834, Rio de Janeiro, Brazil.
Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. May form a superspecies with *E. anneae*. Described taxon *E. vittata* believed to have been a hybrid between present species and *E. pectoralis*. Nominate race, geographically remote from all others, may be better kept apart as a monoptypic species; among other races, geographical differences in voice, in particular of W Amazonian *dilutior* and *brunneifrons* when compared with Andean races, suggest that more than a single species may be involved; in contrast, proposed race *lecroyana* (described from R Chiquito in Táchira, Venezuela) is better lumped with *badissima* due to minimal differences; several other races are poorly differentiated and seem barely recognizable; thorough taxonomic review required. Race *oressinoma* intergrades with *badissima* in N Colombia (W of Ocaña, in Norte de Santander). Eleven subspecies currently recognized.

Subspecies and Distribution.
E. x. chocoensis Hellmayr, 1911 – extreme E Panama (Cerro Pirre, Altos de Quía, Cerro Sapo and R Jaqué) and Pacific Colombia W of Andes (S from Chocó) S to NW Ecuador (N Esmeraldas, Imbabura).
E. x. quitensis (Nelson, 1912) – W Ecuador (S from Pichincha) and NW Peru.
E. x. exsul Berlepsch, 1912 – NE Colombia (Boyacá; N end of Sierra de Perijá), and N cordilleras of Venezuela from Carabobo E to Miranda (Cerro Negro) and N Monagas (Caripe).
E. x. badissima Olson, 1981 – Perijá Mts (Colombia–Venezuela border) and Andes of Venezuela (Lara S to Táchira) and adjacent Colombia (Norte de Santander and Boyacá).
E. x. oressinoma Olson, 1981 – W & C Andes of Colombia (and once on W slope of E Andes in Santander).
E. x. brevirostris Bonaparte, 1851 – E Colombia (upper Magdalena Valley; generally E of Andes from Norte de Santander S to Meta) S to E Ecuador and E Peru (W of Ucayali Valley), E to S Venezuela, C Guyana and NW Brazil (R Uaupés, Tahuapunto).
E. x. dilutior (J. T. Zimmer, 1943) – SE Colombia and NE Peru (Ucayali Valley).
E. x. cyanonota Parkes, 1969 – W & C Brazil from R Juruá (João Pessoa; Lago Grande) and R Purús to R Tapajós.
E. x. brunneifrons Chapman, 1901 – SE Peru (Cuzco and Puno).
E. x. ruficeps d'Orbigny & Lafresnaye, 1837 – Bolivia (La Paz and Cochabamba).
E. x. xanthogaster (Sundevall, 1834) – coastal E Brazil (C Bahia S to C Rio de Janeiro).

Descriptive notes. 9–11 cm; 9–16 g. Variable species with thick, stubby bill. Male nominate race has forehead to slightly beyond mid-crown deep yellow, rest of head and nape glossy blackish, throat purplish-black; upperparts, including upperwing-coverts and flight-feathers, glossy blue-black; uppertail blue-black; breast and lower underparts yellow, belly tinged ochre (not conspicuous); underwing-coverts white; tail grey below, inner webs of several pairs of outer feathers white (forming large white oval-shaped area on each side of undersurface); iris brown; bill mostly black, lower mandible blue-grey with dark tip; legs dark grey. Female has forecrown olive-yellow, mid-crown olive, and distinctly contrasting grey on hindcrown and nape; upperparts olive, upperwing-coverts olive to dusky, edged olive, primary coverts dusky, flight-feathers and tail dusky, feathers edged olive; side of head olive, throat, chest and median underparts grey, contrasting with olive to olive-yellow sides and flanks; belly and undertail-coverts, tinged buff. Subadult male is like female, but by end of first year acquires black mask and sometimes varying amounts of black on head; apparently acquires adult plumage by end of second year. Races differ mainly in colour and pattern of plumage, especially of male, first six

On following pages: 234. Rufous-bellied Euphonia (*Euphonia rufiventris*); 235. Chestnut-bellied Euphonia (*Euphonia pectoralis*); 236. Golden-sided Euphonia (*Euphonia cayennensis*).

below having yellow forehead (like nominate), last four having rufous forehead: *chocoensis* differs from nominate in smaller size, yellow underparts only faintly tinged ochraceous; *oressinoma* is similar to previous in colour, but larger (wing longer, usually more than 63 mm, as opposed to less than 60 mm), bill larger; *brevirostris* male differs from preceding two in having forehead and lower underparts darker, more ochraceous (less yellow), cap plusher, more velvety, without noticeable dark bases of feathers, and bill smaller than *oressinoma*; *quitensis* male has larger yellow cap and darker ochraceous underparts than *oressinoma*; *dilutior* male is much like *brevirostris*, but wing shorter and yellow colours paler, female differs from *brevirostris* in greyer breast (also shorter wing); *cyanonota* male is most like last, but upperparts steel-blue, rather than strongly violaceous, with violaceous only on nape (violaceous colour extends from nape to uppertail-coverts on *dilutior*), and forehead patch possibly does not extend so far back on crown; *brunneifrons* male has forehead patch rufous, is distinctively ochraceous yellow below; *exsul* male has rich orangish-chestnut forecrown, and breast and mid-line of belly very deep fulvous (almost chestnut), female rich buff from breast to undertail-coverts and forecrown tinged chestnut (not yellowish); *badissima* is much like previous, but male has chestnut of forecrown darker, less orangish, and fulvous portions of underparts darker and somewhat more extensive, female forecrown darker and more restricted; *ruficeps* male is very like last, but underparts less deep fulvous. Voice. In Colombia and Venezuela call a nasal, gravelly "nay nay" or nasal, complaining "chee dee" (2–4 notes); song a rambling disconnected "deeu deeu...deet deet deet... jew jew... chu chu chu...jew, ju-du-du-du..." and so on. Elsewhere over range has several different vocalizations, and, in particular, lowland birds of W Amazonia seem to have an almost completely different repertoire of calls and songs, lacking the nasal "nay nay" and other nasal notes of Andean birds; those in foothills in SE Peru differ yet again. Significance of these regional vocalizations (dialects?) has not been examined, but might be worthy of study; some are dramatically different, suggesting that some form of vocal isolation may be occurring.

Habitat. In all areas occurs in humid and wet forest, along forest borders, gaps, treefalls, and in scattered trees in humid clearings. In Andes also in pre-montane and montane rainforest (cloudforest), as well as along wooded borders and in shady plantations. In Amazonia found in both *várzea* and *terra firme* forest, and at least in some areas (e.g. Loreto, in Peru) mainly in forest or older second growth, less in clearings, and scarce or absent on river islands and in young river-edge vegetation. In Venezuela confined to foothills and mountains, mostly 900–1500 m in coastal cordillera, 350–2250 m elsewhere; in Colombia elevational ranges vary from sea-level on Pacific coast to mountains above 300 m (mostly 1300–2100 m in NE Colombia), in Ecuador in lowlands on both sides of Andes and locally to at least 1500 m; in Peru occurs in Amazonian lowlands, and on E slope of Andes to c. 2000 m; widespread in lowlands of W Amazonian Brazil; locally on coast and in mountains of E Brazil from Bahia S to Rio de Janeiro.

Food and Feeding. Fruits and berries; some insects, also spiders (Araneae). Contents of five stomachs were vegetable matter, including mistletoe berries (Loranthaceae) and fig (*Ficus*) fruits. In study in Colombia (R Anchicayá at 900–1100 m, in W Valle), recorded as eating more than 40 species of fruit (89% of all feeding records); melastome fruits of various species comprised 56% of all fruit eaten, *Miconia* berries accounting for 73% of all melastome fruits eaten; also took fruiting spikes of arums (Araceae; 11%), fruits of epiphytes and mistletoe (10%), and catkins of *Cecropia* (8%). Flowers (or flower parts), including catkin-like flower buds of arums and flowers of melastome *Topobea brachyura*, comprised 6% of all feeding records; insect captures comprised 5% of foraging records. Usually occurs in pairs, and in almost all areas pairs are regular members of mixed-species flocks in canopy or upper levels of forest, also sometimes much lower; also readily comes to favourite fruiting trees or shrubs with other frugivores, especially *Tangara* tanagers and other euphonias. In lowland forest found primarily in canopy, but regularly lower along forest borders; in Andes often forages at lower levels. In W Valle (Colombia) study, foraged from about eye level in bushes to canopy, but more at intermediate levels inside forest, where median foraging height was c. 4·5 m (295 observations). Typically perched on branches or twigs, occasionally hovered to take small fruits (3–8 mm in size), and clung to fruiting spikes or picked at capsules of large fruits. Captured insects mostly by sallies or flutter-pursuits to air; noted also as picking insects and/or spiders (Araneae) from spider webs, and occasionally reached up, stretching, to take small insect prey from a leaf surface or a petiole. Foraging records from Peru and Bolivia similar, but median foraging height was c. 9 m (31 records).

Breeding. In Colombia, seven nests in Nov–Apr in W Valle and birds in breeding condition in May–Jul in Perijá Mts; adult feeding young in Nov in C Peru (Pasco), and fledglings at two sites mid-Feb to early Mar in SW Ecuador (El Oro; Loja). Nest a domed (covered) grass-and-moss structure with side entrance, usually a few metres above ground. Male may breed when in subadult (mostly greenish) plumage. No other information.

Movements. Primarily resident. Some seasonal wandering has been noted, but no significant movements reported.

Status and Conservation. Not globally threatened. Widespread and generally common W of Andes and in Amazonian lowlands. Occurs in many protected areas; found also in many unprotected sites that appear not to be at at risk, at least in the short term. Isolated nominate race in SE Brazil occurs in a region now heavily deforested; this population should be monitored closely.

Bibliography. 234. Rufous-bellied Euphonia

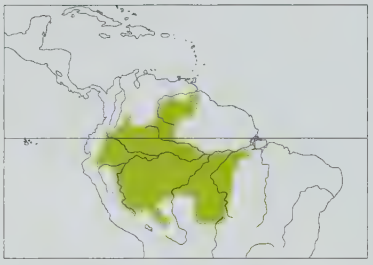
Euphonia rufiventris

French: Organiste à ventre roux **German**: Rotbauchorganist **Spanish**: Eufonia Ventrirrufa

Taxonomy. *Tanagra rufiventris* Vieillot, 1819, locality unknown = Iquitos, Peru.



Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. May form a superspecies with *E. pectoralis* and *E. cayennensis*. Two subspecies recognized.

Subspecies and Distribution.

E. r. carnegiei Dickerman, 1988 – S Venezuela S to headwaters of rivers Orinoco, Ventuari, Cauca, Paragua and Cuyuní.

E. r. rufiventris (Vieillot, 1819) – E Colombia S to E Ecuador, SE Peru (Carabaya) and N Bolivia (R Surutú, in Santa Cruz), and Amazonian Brazil (E to R Negro and vicinity of R Xingu).

Descriptive notes. 10 cm; 13–18 g. Smallish euphonia with short, stout bill, male distinctive in having no yellow forehead patch and no white in tail. Male nominate race has head to throat and centre of chest and entire upperparts, including shoulder and upperwing-coverts, glossy dark steel-blue; flight-feathers and tail dusky, edged and tinged dark steel-blue; rest of underparts orange, this

colour extending up on side of chest, where more golden-yellow; golden-yellow pectoral patch (usually hidden beneath wing); iris dark brown; upper mandible and tip blackish, cutting edge of upper mandible and all except tip of lower mandible pale blue-grey; legs dark grey. Female is darkish olive above, with yellowish tinge on forehead and greyish on nape; chin yellowish, throat and underparts mostly grey, sides and flanks olive-yellow, undertail-coverts contrastingly tawny. Juvenile undescribed. Race *carnegiei* male differs from nominate in darker blue upperparts and darker tawny on lower underparts (belly, flanks, undertail-coverts), female overall darker, more olive (less yellow-green), than nominate, and often with weak metallic blue gloss on upperparts. Voice. Commonest call a rough, low-pitched rattle, "j'a'a'a'a, j'a'a'a'a, j'a'a'a'a", the series varying from two to six rattles, and with gravelly quality; at a distance could be mistaken for a large cicada (Cicadidae). Song not definitely described, but two female-plumaged birds in top of 30-m tree gave what was possibly a duet; one gave a series of "zeet" notes, the other "zit-zit, wit-wit, what-eeeee" ("wit" notes lower-pitched), this short series repeated over and over for several minutes, the two birds turning first one way, then the other, and flicking tail from side to side.

Habitat. Canopy of humid and wet *terra firme* and *várzea* forest, and regularly found along forest borders, tall second-growth woodland and occasionally tall shade trees in humid clearings. Lowlands to 1100 m on tepuis of S Venezuela; elsewhere mainly lowlands up to c. 500 m; in small numbers in foothills to 700–900 m in Ecuador and to 1000 m in Peru.

Food and Feeding. Variety of small fruits and berries, including mistletoe berries (Loranthaceae). Contents of four stomachs were vegetable matter, including fruit pulp and *Cecropia* seeds. Most often mashes fruit before swallowing. Most often seen alone or in pairs (seldom small groups), and a regular member of mixed-species flocks in canopy of lowland rainforest; in general not particularly conspicuous, perhaps because it usually stays so high. Often twitches tail to one side. Only infrequently associates with other members of its genus around mistletoe clumps. Forages mostly in canopy or subcanopy, and spends much time in and around epiphytes, including especially large bromeliads, high in canopy and in emergent trees. Noted as taking small berries from a large bromeliad c. 34 m up in canopy in NE Peru.

Breeding. No information.

Movements. Resident.

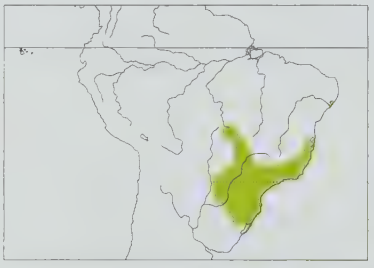
Status and Conservation. Not globally threatened. Fairly common to common, and widespread across W & C Amazonia. Occurs in numerous protected areas, and its range encompasses extensive intact forest habitat that, while unprotected, faces little or no threats in the short term.

Bibliography. Dickerman (1988), Dunning (1982), Gilliard (1941), Haffer (1970), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Laubmann (1936), Meyer de Schauensee (1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Naumburg (1930), O'Neill (1974), Parker *et al.* (1982), Pearson (1977), Remsen *et al.* (1987), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schubart *et al.* (1965), Schulenberg (2000c), Schulenberg *et al.* (2007), Sick (1985, 1993), Snethlage (1914), Souza (2002), Terborgh & Weske (1969), Zimmer (1943a).

235. Chestnut-bellied Euphonia

Euphonia pectoralis

French: Organiste à ventre marron **Spanish**: Eufonia Ventricastaña



German: Braunbauchorganist

Other common names: Black-throated Euphonia ("*E. vittata*")

Taxonomy. *Pipra pectoralis* Latham, 1801, Rio de Janeiro, Brazil.

Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. May form a superspecies with *E. rufiventris* and *E. cayennensis*. Described taxon "*E. vittata*" believed to have been a hybrid between present species and *E. xanthogaster*. Monotypic.

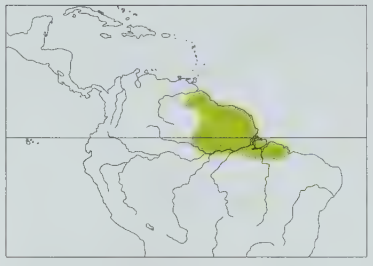
Distribution. E & SE Brazil (Alagoas; C Mato Grosso and S Bahia S to Santa Catarina), adjacent E Paraguay and NE Argentina (Misiones).

Descriptive notes. 11 cm; 15–16·5 g. Rather small euphonia with thick bill, male distinctive in having no yellow forehead patch and no white in tail. Male has head to breast and entire upperparts, including upperwing-coverts, highly glossed metallic blue; flight-feathers and tail dusky, edged and tinged metallic blue (less so on primaries); belly and lower underparts dark chestnut except for metallic blue thighs, golden-yellow pectoral tuft often protruding beneath wing; iris dark brown; tip and variably rest of upper mandible blackish, cutting edge of upper mandible most of lower mandible blue-grey; legs dark grey. Distinguished from similar *E. rufiventris* mainly by much darker coloration, especially on lower underparts. Female has forecrown dull yellowish, rest of crown to central nape grey, upperparts olive; mostly grey below, sides and flanks yellow-olive, vent and undertail-coverts dark rufous. Juvenile undescribed. Voice. Call a series of up to five coarse, low-pitched rattles, "j'a'a'a'a, j'a'a'a'a, j'a'a'a'a...", delivered rather slowly; much like that of *E. rufiventris*. Song a short, harsh series of warbled notes that may include imitations of other birds.

Habitat. Canopy of humid forest, along forest borders and in tree-scattered clearings. Sea-level to 1550 m in mountains in SE Brazil; lowland in adjacent NE Argentina.

Food and Feeding. Small fruits, including those of melastomes, epiphytes, epiphytic cacti, *Cecropia*, palms, and *Solanum*; observed also to take small arthropod prey from bark surfaces. Seen to probe at flowers for nectar and/or insects, and to take sugar water from hummingbird (Trochilidae) feeders. Usually singly, in pairs or in small groups, and regularly with mixed-species flocks. Forages from middle heights to canopy; often perches in the open, or in open trees such as *Cecropia*, where it is active and easily seen. Behaviour in general similar to that of *E. rufiventris*, although can be more conspicuous.

Breeding. Breeding reported in Jan in SE Brazil (Rio de Janeiro) and Aug in Paraguay. Dome-shaped nest with small side entrance, made from mosses and ferns, much like those of congeners,



c. 2 m or a bit higher above ground and concealed on side of trunk, in suspended roots of epiphytic fern, amid epiphytes on large limb or in branches of bush; two were in niche on steep bank. One nest contained 3 eggs. No other information.
Movements. Resident. Reports that this species may wander or undertake seasonal elevational movements in part of range need confirmation.
Status and Conservation. Not globally threatened. Fairly common and widespread in SE Brazil and in extreme NE Argentina and E Paraguay. Deforestation extensive over most of its range, but generally numerous in remaining forests. Occurs in a number of protected areas, e.g. Iguazú National Park (Argentina) and adjacent Iguaçu National park (Brazil); and Itatiaia, Serra dos Órgãos and Tijuca National Parks, Augusto Ruschi (Nova Lombardia) Biological Reserve and other protected areas in coastal Atlantic range. Relatively little intact habitat remains outside protected areas.
Bibliography. dos Anjos & Schuchmann (1999), Belton (1985), Bertoni (1901, 1919), Davis (1945b, 1946), Descourtilz (1852), Diamond & Lovejoy (1985), Dunning (1982), Haffer (1970), Holt (1928), Isler & Isler (1999), McCarthy (2006), Narosky & Di Giacomo (1993), Nitzsche (1994), Parker & Goerck (1997), de la Peña & Rumboll (1998), Ridgely & Tudor (1989, 2009), Rocca & Sazima (2008), Sick (1985, 1993), Snethlage & Schreiner (1929), Souza (2002), Willis (1979).

236. **Golden-sided Euphonia**

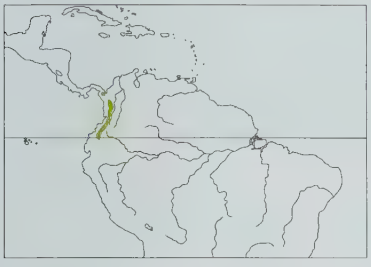
Euphonia cayennensis

French: Organiste nègre **German**: Cayenneorganist **Spanish**: Eufonia Negra

Taxonomy. *Tanagra cayennensis* J. F. Gmelin, 1789, Cayenne, French Guiana.
Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. May form a superspecies with *E. rufiventris* and *E. pectoralis*. Monotypic.
Distribution. SE Venezuela (E Bolívar), the Guianas, and NE Brazil from Manaus E (on both sides of R Amazon) to Pará and N Maranhão.
Descriptive notes. 11 cm; 11·8–16 g. Smallish, relatively short-tailed, stout-billed euphonia, male distinctive with almost wholly dark plumage. Male is entirely dark glossy steel-blue above and below, including wing-coverts and entire underparts; flight-feathers and tail dusky, edged and tinged dark steel-blue; long golden-yellow feathers of pectoral patch usually protrude conspicuously in front of and below bend of wing; iris dark brown; upper mandible blackish, with blue-grey along basal half, lower mandible blue-grey with blackish tip; legs dark grey. Female has forehead tinged yellowish, otherwise crown and entire upperparts olive; underparts, including belly and undertail-coverts, almost entirely grey, with olive-yellow on sides and flanks. Juvenile undescribed. Voice. Call a low, coarse, gravelly "j'a'a'a'a" repeated 2–6 times, sometimes quickly; almost identical to

that of *E. rufiventris*. Also gives longer, faster, and buzzy rattle, "bjjjjjjjjjjjjjjjjj", c. 2 seconds, and a higher, softer and nasal "ruee-e-et", run together and rather like that of several other members of genus. A possible duet consisting of a short flat whistle and series of short "tu" notes, along with burry notes in random order, has been reported.
Habitat. Occurs in canopy of humid lowland forest and forest borders, in some areas also in scrubbier, drier, and lower-canopied patches of savanna forest, as well as second growth. Found in lowlands up to c. 600 m, locally up to 1100 m.
Food and Feeding. Food is not well documented; mostly small berries and fruit, and probably some insects. Two stomachs contained only berries. Often encountered singly or in pairs, much less frequently in small groups; wanders alone or sometimes associates with other euphonia species or mixed-species flocks in canopy or upper levels of rainforest. Sometimes comes quite low to small fruiting shrubs along forest borders. Often wags or twitches its tail to one side, or from side to side in mechanical fashion. Not regularly seen around mistletoe (Loranthaceae), but does take eat mistletoe berries on occasion.
Breeding. Breeding recorded in Nov in Brazil (Pará). Nest in Brazil rounded or covered and with side entrance, much like those of congeners, made from moss and root fibres, lined with fine vegetable fibres, placed 1 m up; two reported cases of use of abandoned tyrant-flycatcher (Tyrannidae) nest, one a nest of Ochre-bellied Flycatcher (*Mionectes oleagineus*) located inside forest, the other of a *Myiozetetes* species c. 1 m up in fruit tree in second growth. Clutch 3–5 eggs, whitish with a few red spots; female observed to be incubating in the *Myiozetetes* nest. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common; in most areas present at low density. Occurs in several large protected areas, including Canaima National Park (Venezuela), Kaieteur National Park and Iwokrama Forest Reserve (Guyana), Brownberg Nature Park and Raleighvallen/Voltsberg Nature Reserve (Suriname); Guyana Amazonian Park (French Guiana), and Montanhas do Tumucumaque National Park (Brazil). In addition, the species' range includes large amounts of intact unprotected forest that is at little immediate risk.
Bibliography. Beebe (1916), Boesman (1998), Gilliard (1941), Haffer (1970), Haverschmidt & Mees (1994), Hilty (2003), Ingels (1975), Isler & Isler (1999), Layard (1873), Meyer de Schauensee & Phelps (1978), Novaes (1970), Pinto (1944b), Restall *et al.* (2006), Ridgely & Tudor (1989, 2009), Sick (1985, 1993), Snethlage (1935a), Snyder (1966), Souza (2002), Tostain *et al.* (1992), Willis (1977).

Genus *CHLOROPHONIA* Bonaparte, 1851



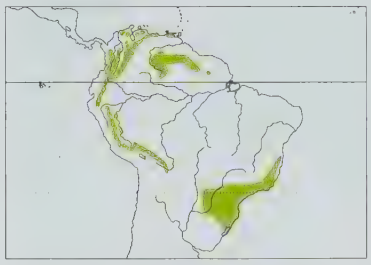
237. **Yellow-collared Chlorophonia**

Chlorophonia flavirostris

French: Organiste à col jaune **German**: Halsbandorganist **Spanish**: Clorofonia Acollarada
Other common names: Yellow-collared Tanager

Taxonomy. *Chlorophonia flavirostris* P. L. Sclater, 1861, locality unknown, possibly west Ecuador. Genus has sometimes been merged with *Euphonia*; recent molecular-genetic analysis indicates that both genera belong in family Fringillidae. Two races proposed, *minima* (described from La Guayacana, in Nariño) and *boehmi* (based on aviary bird, origin uncertain), but nomadic behaviour of this species suggests that recognition of geographical races is problematic. Treated as monotypic.

Distribution. Extreme E Panama on Cerro Pierre (once), W slope of W Andes of Colombia from Risaralda–Antioquia border (Alto de Pisones on Cerro Caramanta) S to W Ecuador (S to Pichincha).
Descriptive notes. 10 cm; 11–12·4 g. Small, with short tail, chunky shape, stubby bill and colourful plumage. Male has glistening emerald-green head, throat and chest, prominent yellow eyering (particularly conspicuous against whitish iris), and yellow collar that completely encircles neck (yellow on side of neck often hidden beneath bend of wing); upperparts and upperwing-coverts glistening emerald-green, rump and uppertail-coverts bright yellow; flight-feathers dusky, edged emerald-green, tertials and tail extensively green; narrow partially concealed line of chestnut on side of chest, separating green of bib from bright yellow centre of breast, belly and undertail-coverts; sides and flanks bright green; iris greyish-white; bill bright orange to salmon-orange; legs bright orange. Female is mainly uniformly grass-green (duller than male), flight-feathers dusky, edged green, tertials and tail extensively grass-green, centre of breast fading to yellow, and belly and undertail-coverts bright yellow; bill and eyering similar to those of male but duller, eyering and pale iris conspicuous. Immature resembles female, but bare parts even duller; age stages and plumage sequence unknown (most flocks composed predominantly of individuals in female-like plumage). Voice. A rather quiet species, uttering soft "pek" notes when foraging. In flight, also occasionally when perched, a soft, plaintive "peeeeeeee", often repeated over and over. A weak chattering vocalization is possibly a song.



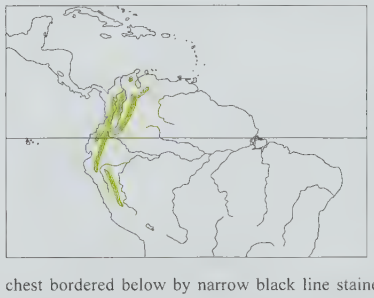
Habitat. Found mainly in canopy of humid to very wet (pluvial) lowland and pre-montane forest, along forest borders and in taller, older second-growth woodland, especially on steep slopes. Although regularly occurs down to edge of coastal plain in Pacific Colombia, seems not to range widely in lowland forest and is perhaps only seasonal or local there. Lowlands (c. 100 m) to 1900 m (most records from near base of foothills to c. 1200 m) in Colombia; c. 450–1500 m in Ecuador.
Food and Feeding. Almost exclusively small berries and fruit; recorded as eating at least those of nine species, figs (*Ficus*) comprising 40% of all fruit records, *Miconia* berries 37%, and documented as feeding also on fruiting stalks of *Schefflera* (Araliaceae). In one study, observed to capture insect prey only twice in 82 observations. One stomach contained only fluid. Occurs mainly in pairs or parties of 3–7 individuals that forage alone or associate for varying amounts of time with mixed-species flocks containing other tanagers. In Colombia, gathers seasonally in much larger flocks of up to 30 individuals, rarely of more than 100, composed mostly of birds in female-like plumage, which move mostly independently of mixed-species flocks. Also often comes to favourite fruiting trees to forage when other tanagers and small frugivores are present, sometimes remaining well after other species have departed. Forages mostly in crowns of tall trees; median foraging height c. 14 m. When foraging, perches rather horizontally on branch or twig, moves in active but deliberate fashion in outer foliage, and hops from branch to branch to locate small berries; takes these mainly while perched, occasionally snatches them in flight. Noted as perching on large fruits. Observed to hang downwards from a leaf petiole to peer beneath a leaf when apparently searching for insects.
Breeding. In Colombia, nest being built in Apr at Cerro Caramanta (c. 1550 m), on Risaralda–Antioquia border, dome-shaped, 8 m up in fork of small dead tree; another under construction in early May in Pialapi Valley (1740 m) forest border, in SW Nariño, male accompanied female, only female carried material, closed nest of moss and grass with side entrance, placed c. 14 m up in canopy and near trunk of mossy *Alchornea* (Fabaceae). No other information.
Movements. Wanders both horizontally and elevationally; at times disperses in pairs or small groups, at other times gathers in large flocks. Movements believed to be primarily over short distance; altitudinal movements may be seasonal. In Anchicayá Valley (1050 m), in Colombia, present in all months but numbers varied dramatically; Jun–Jul flocks of 30–80 in valley foothills at 100–200 m. In Ecuador, believed to be present mainly Dec–Apr in vicinity of Chiriboga road and near Mindo.
Status and Conservation. Not globally threatened. Restricted-range species: present in Darién Highlands EBA and Chocó EBA. Uncommon to common locally or seasonally. This species was virtually unknown in the wild three or four decades ago; despite bright plumage, easily overlooked because of soft calls and habit of remaining within foliage. Occurs in a few protected areas, including Farallones de Cali National Park and possibly El Pangán Bird Reserve, both in Colombia. Has small global range, and deforestation has reduced, and continues to reduce, the amount of habitat available to it, especially in departments of Cauca and Nariño, in Colombia, and in adjacent Ecuador. While the population may not, at present, qualify for threatened status, this species should be monitored.
Bibliography. Buchi (1984), Burns (1997a), Burns *et al.* (2002, 2003), Capparella (1986), Dunning (1982), Gyldenstolpe (1941a), Hesse & Hesse (1982), Hilty (1977, 2009a), Hilty & Brown (1986), Ingels (1979), Isler & Isler (1999), Moore *et al.* (1999), Restall *et al.* (2006), Ridgely (1980), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Strewe (2001a).

238. **Blue-naped Chlorophonia**

Chlorophonia cyanea

French: Organiste à nuque bleue **German**: Grünorganist **Spanish**: Clorofonia Nuquiazul
Other common names: Blue-naped Tanager

Taxonomy. *Pipra cyanea* Thunberg, 1822, locality uncertain, possibly Rio de Janeiro, Brazil.
Genus has sometimes been merged with *Euphonia*; recent molecular-genetic analysis indicates that both genera belong in family Fringillidae. Nominate race extremely isolated geographically; other races may be better split off as a distinct species. Races *psittacina*, *frontalis* and *minuscula* are all very similar, and may not warrant subspecific separation. Seven subspecies tentatively recognized.
Subspecies and Distribution.
C. c. psittacina Bangs, 1902 – Santa Marta Mts, in N Colombia.
C. c. frontalis (P. L. Sclater, 1851) – mountains of N Venezuela (Falcón and Lara E to Miranda).
C. c. minuscula Hellmayr, 1922 – mountains of NE Venezuela (Anzoátegui, Monagas and Sucre).
C. c. intensa J. T. Zimmer, 1943 – W slope of W Andes (in Caldas and Valle), in Colombia.
C. c. longipennis (du Bus de Gisignies, 1855) – Andes from W Venezuela (S from S Lara) S generally through Colombian ranges (except W slope of W Andes), Ecuador and Peru to Bolivia (to Cochabamba and W Santa Cruz).
C. c. roraimae Salvin & Godman, 1884 – tepuis of S Venezuela (Amazonas and Bolívar) E to Guyana and in mountains of extreme NW Brazil (R Padauiri, on Venezuela border).
C. c. cyanea (Thunberg, 1822) – SE Brazil (S from S Bahia) S to E Paraguay and NE Argentina (Misiones).
Descriptive notes. 11 cm; 11–15 g. Short-tailed, with chunky shape, stubby bill and colourful plumage. Male nominate race has head, throat and chest glistening emerald-green, bold bright turquoise-blue ocular ring, narrow cobalt-blue nuchal collar, feathers of mantle, scapulars and marginal to median upperwing-coverts green, broadly edged blue, central back to uppertail-coverts blue, lighter and brighter on rump, flight-feathers dusky, edged bright green, tail dusky with green-blue edges; breast and lower underparts bright yellow, underside of tail grey; iris dark brown; bill blackish; legs dark grey. Female is much duller and plainer than male, mainly green, ocular ring and narrow nuchal collar blue, breast and lower underparts dull greenish-yellow. Immature male is similar to female, but may lack blue on nape. Race *roraimae* very similar to nominate but has yellow base of forehead; *longipennis* male similar to nominate but with blue of upperparts extending barely (or not at all) onto scapulars and wing-coverts, underparts brighter yellow; *intensa* very similar to previous, but underparts much duller yellow; races *psittacina*, *frontalis* and *minuscula* all very similar and doubtfully separable, male with lower forehead yellow and back green, but hindneck and rump blue, as in all races, and female dull golden-olive below; *minuscula* is somewhat smaller



than the other two, with underparts duller in male. Voice. Calls include a soft nasal "ek" or "enk" note, apparently mainly as for contact when birds are perched or foraging; also a soft pleading "pleeeeee" (much like that of *Euphonia cyanocephala*) during foraging, and especially just before taking flight. Other vocalizations include a nasal "peent" and short, gravelly rattle. Song, in all areas, a choppy and rather unmusical series of call notes, liquid whistles, soft notes and sharp or smacking notes at fairly brisk pace.
Habitat. In most areas found mainly in humid and wet pre-montane and montane forest, at forest borders, and in tall or older second-growth woodland, sometimes also in tall trees in clearings; locally in lowlands (near Andes) in W Amazonia and found almost down to sea-level in SE Brazil. In Venezuela, recorded at 700–2500 m in mountains N of R Orinoco and at 500–1800 m in tepuis in S; 600–2100 m (mostly above 1400 m) in Colombia, and mainly 800–1700 m (one record in E lowlands possibly involved a vagrant) in Ecuador; mainly 900–2100 m in Peru, but at least seasonally ranges out into Amazonian lowlands of SE, where small numbers as low as 300 m.
Food and Feeding. Almost exclusively fruit; some insects. Takes variety of small berries, especially those of *Miconia*, and in Paraguay takes fruit of *Allophyllus edulis*. Size of fruit recorded in diet ranges from 3 mm to 10 mm; pecks pieces from the larger fruits. Contents of five stomachs were vegetable matter, including mistletoe seeds (Loranthaceae) and other seeds and fruit. Occurs in pairs or, more often, in families or groups up to about twelve individuals. Often spends long periods of time in clumps of mistletoe, moving around relatively little; sometimes moves quite actively, following mixed-species flocks containing *Tangara* and other tanagers. Forages mainly from middle levels to high in canopy, and generally inconspicuous except for occasional soft calls. Has been noted as gleaning for insects on mossy limbs and sallying to foliage. Takes fruit mostly by reaching or leaning over to grasp it while perched.
Breeding. In Colombia, three nests found in May in Santa Marta Mts, nest-building observed Jan and Jun and four begging juveniles in May and Jul in Valle, and twelve birds in breeding condition in Apr and May in N & W; nest-building in Nov in C Peru (Pasco); male and female gathering nest material in late Nov in NE Argentina (Puerto Iguazú). Grassy ball-shaped nest with side entrance, placed in crevice in vertical bank or cliff. Clutch 3 eggs, white, sprinkled with chestnut, more heavily at large end; nestlings fed apparently by regurgitation. No other information.
Movements. Some seasonal movements, especially elevational shifts in mountains; in Peru, individuals present at least Jun–Aug in R Madre de Dios area (near Boca Manu), suggesting some seasonal movement between highlands and lowlands. More information on seasonal movement required.
Status and Conservation. Not globally threatened. Rare to locally fairly common. Widespread in montane regions, although distribution somewhat patchy, with abundance variable. Occurs in numerous protected areas in every country where it occurs. The species' range also includes considerable intact habitat which, although unprotected, is at relatively little risk in foreseeable future. Deforestation in Andean and Atlantic coastal portions of range is the greatest threat to this species. In SE Brazil present in a number of protected areas, among them Augusto Ruschi (Nova Lombardia) Biological Reserve and Itatiaia, Tijuca and Iguaçu National Parks, but in this region relatively little habitat outside protected areas is available to this species.
Bibliography. Álvarez-Rebolledo *et al.* (2003), Barrowclough & Escalante-Pliego (1990), Belton (1985), Bertoni (1901, 1919), Di Giacomo *et al.* (1995), Euler (1900), Fjeldså & Krabbe (1990), Gilliard (1941), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Kleefisch (2011), LaVerde *et al.* (2005), Lysinger *et al.* (2005), Meyer de Schauensee (1966, 1970a), Meyer de Schauensee & Phelps (1978), Miller (1963), Narosky & Di Giacomo (1993), Ottavio *et al.* (2008), Parker & Goerck (1997), de la Peña & Rumboll (1998), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989), Salaman, Donegan & Caro (2008), Salaman, Stiles *et al.* (2002), Santos (1948), Schäfer & Phelps (1954), Schulenberg (2000a), Schulenberg *et al.* (2007), Sick (1985, 1993), Snyder (1966), Souza (2002), Todd & Carriker (1922), Wetmore (1939), Zimmer (1943a).

239. **Chestnut-breasted Chlorophonia**

Chlorophonia pyrrhophrys

French: Organiste à ventre brun **Spanish**: Clorofonia Pechicastaña
German: Schwarzbrauenorganist
Other common names: Chestnut-breasted Tanager

Taxonomy. *Euphonia pyrrhophrys* P. L. Sclater, 1851, "Bogotá".
Genus has sometimes been merged with *Euphonia*; recent molecular-genetic analysis indicates that both genera belong in family Fringillidae. Monotypic.
Distribution. Sierra de Perijá (Colombia–Venezuela border), and Andes of W Venezuela (S from Trujillo) S to Colombia (Norte de Santander; locally in W & C ranges), Ecuador (S on W slope to Pichincha, on E slope locally to Loja), and on E slope S to Peru (on Piura–Cajamarca border, and locally from Amazonas S to Huánuco).

Descriptive notes. 12 cm; 16–18 g. Short-tailed, short-billed and chunky, with colourful, strongly marked plumage. Male has base of forehead green, rest of crown and nape rich cyanine-blue, narrowly bordered dark red (often looks black) at front and side; narrow nape band paler blue; lores, ocular area, side of head and neck, and throat and chest glistening emerald-green; mantle, back and upperwing-coverts bright green, rump bright yellow; primary coverts and flight-feathers blackish, edged bright green, tertials mainly green; central tail feathers dusky, narrowly edged green, outer feathers with broader green edgings; green of chest bordered below by narrow black line stained with chestnut (this border sometimes partly concealed); underparts bright yellow, median band down breast and belly and entire undertail-coverts deep chestnut (some males have broader band extending almost to sides and flanks, partly

On following pages: 240. Blue-crowned Chlorophonia (*Chlorophonia occipitalis*); 241. Golden-browed Chlorophonia (*Chlorophonia callophrys*); 242. Puerto Rican Tanager (*Nesospingus speculiferus*).

obscuring the yellow in this area); iris dark brown; bill blackish, base of lower mandible pale grey; legs dark grey. Female is duller than male, and mainly green; crown and nape turquoise-blue, bordered by narrow chestnut line along front and side of crown, with lowermost forehead, lores, side of head (including ear-coverts) and throat and chest bright green; back and rump green (slightly darker than throat), upperwing-coverts dusky, broadly edged and tinged dark green, flight-feathers blackish, basal two-thirds of feathers edged dark green, tertials mostly green; breast and belly dull yellowish, rather sharply cut off from green of throat and chest. Immature is mostly dull green, with breast and belly yellowish. VOICE. Commonest call a soft, nasal "neck-nuur" repeated over and over, or occasionally 3–4 notes in the series; contact call a nasal, downslurred whistle, "teeeur", sweet but penetrating in quality and much like that of *Euphonia cyanocephala*. Song a long, rambling and rather weak series of call notes and various soft, sharp and nasal notes, "tut-tut-tut too-dée too-dée..." or "na-déar, na-déar... to-d'leép", with variations.

Habitat. Humid and wet montane forest, especially heavily epiphyte-laden forest (cloudforest), along forest borders and in older second-growth woodland. Occasionally in stunted forest almost up to tree-line. At 1800–3000 m in Venezuela; 1400–2700 m in Colombia; mostly 1500–2750 m (rarely to 3000 m) in Ecuador; c. 1500–2500 m (most records above 1700 m) in Peru.

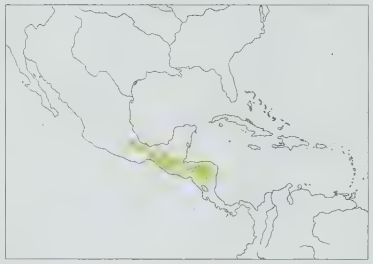
Food and Feeding. Mostly berries of mistletoe (Loranthaceae), also berries of various species of Ericaceae, and observed to eat fruit of figs (*Ficus*) in Colombia; occasionally insects. Found mainly in pairs, somewhat less often in families or small groups; much more often independent of mixed-species flocks than with them, and rather infrequently with other birds at fruiting trees. Forages mostly in mossy canopy, often spending long periods of time in large epiphytic clumps and not moving much; occasionally peers at twigs, epiphytes and moss for small insects.

Breeding. Nest-building in Mar in Venezuela. Both sexes observed to bring material, nest apparently a tight, domed structure of tendrils and fibres, with small side entrance, placed in niche c. 6 m up on high wet road bank at forest edge. No other information.

Movements. Resident. Perhaps some local movements in response to food abundance; reported as occurring locally or seasonally to as high as 3000 m in Ecuador.

Status and Conservation. Not globally threatened. Rare to uncommon over most of range. Probably declining. Present in numerous protected areas, including Sierra Nevada National Park (Venezuela), Farallones de Cali National Park and Tambito Nature Reserve (Colombia) and Tingo Maria National Park (Peru). The species' range also includes intact unprotected montane forest, at least some of which appears to be at relatively low near-term risk. Deforestation and the fragmentation of existing montane forest continue to be the two most pressing problems facing this species.

Bibliography. Donegan & Dávalos (1999), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1983, 1986), Isler & Isler (1999), Krabbe *et al.* (2001), Meyer de Schauensee (1966, 1970a), Meyer de Schauensee & Phelps (1978), Miller (1963), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007).



240. **Blue-crowned Chlorophonia**

Chlorophonia occipitalis

French: Organiste à calotte bleue **Spanish**: Clorofonia Coroniazul
German: Blauscheitelorganist
Other common names: Blue-crowned Tanager

Taxonomy. *Euphonia occipitalis* du Bus de Gisignies, 1847, Mexico.
Genus has sometimes been merged with *Euphonia*; recent molecular-genetic analysis indicates that both genera belong in family Fringillidae. Forms a superspecies, and formerly considered conspecific, with *C. callophrys*. Monotypic.

Distribution. E Mexico (from Veracruz) S to N Nicaragua.

Descriptive notes. 13 cm; 25–27·5 g. Short-tailed, with stubby bill, chunky shape and predominantly green-and-yellow plumage. Male has rather small, circular turquoise-blue central crown patch and narrow turquoise-blue nuchal collar; rest of head, throat and chest glistening emerald-green; upperparts, including upperwing-coverts, glistening green (slightly darker than head); primary coverts and flight-feathers black, broadly edged green (wingtips black), tertials bright green; tail green above, grey below; black and chestnut line along lower border of chest (often partly concealed); breast, belly and undertail-coverts bright yellow, yellow extending up narrowly in front of bend of wing; sides and flanks green; iris light brown to brown; upper mandible dusky with some pale bluish-grey at base, lower mandible pale bluish-grey with dusky tip; legs dark grey. Female has crown patch turquoise-blue, as on male, and narrow nuchal band light cerulean-blue, both areas of blue less extensive than on male; otherwise mainly glistening green above, wing as on male, mainly green below, becoming yellow on centre of mid-breast and belly, with undertail-coverts yellow. Juvenile is like female, but duller and may lack blue. VOICE. Most common calls include a rather low, nasal "enk" and "enk-it", and a plaintive downward-inflected whistle, "eeeeeee" (described also as a cooing "peeu" or "hoo"), this sometimes preceded by one to several soft liquid "whuit" notes. Song a long, rather breezy series of "turdle-dee" phrases mixed with rougher, lower-pitched "chup" or "dit" notes, which may possibly be delivered in duet.

Habitat. Humid montane forest, shady plantations, and scattered trees in clearings. Recorded at 500–2500 m, mostly 1000–2000 m; reported at nearly sea-level during winter months.

Food and Feeding. Diet believed to be almost entirely fruit; possibly some insects. Feeds heavily on mistletoe berries (Loranthaceae) and other small berries. Usually in pairs when breeding, but at other times in small groups, occasionally up to nearly a dozen, that stay together mostly high in trees and wander in search of food; may gather temporarily with other birds at fruiting trees, but otherwise generally independent of mixed-species flocks. Forages in canopy. Reported as occasionally searching for insects on mossy branches.

Breeding. Nests found in Apr in Mexico. Nest built by both sexes, a rounded or domed structure with small side entrance, constructed from bark, moss, epiphytic stalks and other fibres, lined with fine fibres, placed 3 m up in bromeliads and epiphytes. Clutch 3 eggs, white with reddish and grey markings, especially at large end; in captivity up to 5 eggs laid, incubation period 15 days, both adults fed young by regurgitation, nestling period 21 days.

Movements. Resident. Some post-breeding wandering or seasonal movements from higher to lower elevations, but poorly documented.

Status and Conservation. Not globally threatened. Common to fairly common in Mexico. Occurs in a few protected areas, including El Triunfo National Park (Mexico), Celaque, Cusuco and La Muralla National Parks (Honduras) and probably several national parks in Guatemala. The species' range has decreased because of extensive deforestation within region, but some intact unprotected habitat remains within its existing range.

241. **Golden-browed Chlorophonia**

Chlorophonia callophrys

French: Organiste à sourcils jaunes **Spanish**: Clorofonia Cejidorada
German: Goldbrauenorganist
Other common names: Golden-browed Tanager

Taxonomy. *Triglyphidia callophrys* Cabanis, 1861, Costa Rica.
Genus has sometimes been merged with *Euphonia*; recent molecular-genetic analysis indicates that both genera belong in family Fringillidae. Forms a superspecies, and formerly considered conspecific, with *C. occipitalis*. Monotypic.

Distribution. Mountains of Costa Rica and W Panama (Chiriquí and Veraguas).

Descriptive notes. 13 cm; c. 24 g. Short-tailed, short-billed, chunky tanager with predominantly green-and-yellow plumage. Male has forehead and long broad supercilium golden-yellow, centre of crown and nape pale violet-blue, narrow nuchal collar turquoise; side of head down to chest, and upperparts glistening emerald-green, eyering turquoise; upperwing-coverts green, flight-feathers blackish, outer feathers narrowly edged green and inner feathers more broadly edged green, tertials mostly green with part of inner web dusky; tail green above, grey below; narrow (often partly concealed) line bordering bottom of bib chestnut mixed black, sharply separating green of bib from bright yellow of breast, belly and undertail-coverts; flanks green; iris brown; upper mandible dusky with some grey at base, lower mandible grey with dusky tip; legs dark grey. Female has yellow forehead, light blue central crown patch extending to narrow dull blue-violet band across nape (often partly concealed); side of head, throat and upperparts glistening green, upperwing-coverts green, flight-feathers and tail blackish, outer remiges narrowly edged green and inner ones (secondaries), tertials and tail broadly edged green; green of throat changes to yellow on mid-breast, belly and undertail-coverts; sides, flanks and thighs strongly tinged green; female very similar to female of *E. occipitalis*, but mid-crown duller and darker, dull blue-violet. Immature male in first year is similar to female, but crown brighter, forehead and supercilium yellowish-green, and foreparts brighter green. VOICE. In Costa Rica, call described as a soft, lamenting "koow" or "keeeu"; contact calls include variety of soft nasal notes, e.g. "neck", and "jip" and "jup", with rising inflection. Song a jumble of short but clear and melodious notes, rather disconnected, all given rather softly.

Habitat. In canopy and along borders of tall, wet forest (cloudforest), especially mossy, epiphyte-laden trees; wanders to canopy of scattered tall trees in forest clearings, less often also in lower second growth when small berries present. In Costa Rica, from c. 900 m up to tree-line on Caribbean slope and c. 1500 m to tree-line on Pacific slope, and seasonally lower, especially on Caribbean slope.

Food and Feeding. Mainly fruits of mistletoes (of genera *Gaiadendron*, *Psittacanthus*), berries of Ericaceae, Araceae, Marcgraviaceae and other epiphytes, as well as figs (*Ficus*); small number of insects. Rear of body often contorted or wiggled from side to side when defecating sticky strings of seeds. Rather quiet and easily overlooked. In pairs when breeding, but for much of year found in small loose groups of up to a dozen; occasionally for short periods with mixed-species flocks. Often spends long periods of time in a single epiphyte-covered tree if sufficient numbers of small berries. Takes insects by hopping and leaning down to peer under twigs.

Breeding. Season Feb–Jun in Costa Rica; second nesting may be attempted within two weeks of fledging of first brood. Nest built by both sexes, a globe-shaped structure with small entrance hole on side (walls 0·6–1 cm in thickness, inner chamber c. 8–9 mm in diameter and height), consisting mainly of moss or with moss, grasses, liverworts, cow hair, vegetable hair and even dried orchids, typically located amid bromeliads and other epiphytes 11–30 m up on branch or trunk, also reported 2 m up on vertical road-cut bank and 200 m from forest in Costa Rica. Clutch at least 3 eggs, dull white, spotted with red-brown blotches in wreath around larger end; incubation by female alone, sometimes fed at nest by male (by regurgitation), no information on duration of incubation period; chicks fed by both sexes, by regurgitation, nestling period 23–25 days.

Movements. Not well documented. Small groups wander somewhat when not breeding. Some seasonal elevational movements, individuals descending well below breeding zone during rainy months when fruit scarce.

Status and Conservation. Not globally threatened. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Fairly common to locally common in Costa Rica; uncommon in Panama. Has experienced extensive habitat loss from deforestation. Remains fairly common to common locally in Costa Rica, uncommon in Panama. Occurs in numerous protected areas, including Poas, Volcán Irazú, Braulio Carrillo and Chirripó/La Amistad National Parks (Costa Rica) and La Amistad and Volcán Barú National Parks (Panama). The species' range does not include a large amount of intact habitat outside protected areas. While it is not considered to become at risk in the near future, populations would seem to warrant monitoring, especially in the small Panama portion of its range, where deforestation is severe.

Bangs & Griscom (1932), Buskirk (1976), Carriker (1910), Davis (1972), Garrigues & Dean (2007), Hartman (1955), Isler & Isler (1999), Peralta (2007), Powell (1979), Ridgely & Gwynne (1989), Skutch (1953, 1954), Slud (1964), Stiles & Skutch (1989), Wetmore *et al.* (1984), Wheelwright *et al.* (1984).

Genus *NESOSPINGUS* P. L. Sclater, 1885

242. **Puerto Rican Tanager**

Nesospingus speculiferus

French: Pleureur de Porto Rico **German**: Brustfleckentangare **Spanish**: Tangara Puertorriqueña

Taxonomy. *Chlorospingus* (?) *speculiferus* Lawrence, 1875, Puerto Rico.
Recent molecular-genetic studies indicate that this genus and *Chlorospingus*, *Spindalis* and *Phaenicophilus* form a monophyletic clade that is sister to several New World warbler (Parulidae) genera (including *Dendroica*, *Basileuterus* and *Vermivora*), and are not closely related to other genera of present family. Monotypic.
Distribution. Slopes of Sierra de Luquillo (in Carite-Guavate State Forest), in Puerto Rico.

Descriptive notes. 18–20 cm; 28·7–40 g. Large size, rather drab plumage, with contrasting white throat, and fairly stout bill. Has head to below eye, including ear-coverts, dusky brown (hooded appearance); narrow, slightly irregular moustachial line blackish-brown; upperparts dull olive-brown; upperwing-coverts brown (slightly paler than back), primary coverts blackish, flight-feathers dusky, edged brown, small white spot at base of primaries; throat white, contrasting with slightly duller breast and lower underparts, which are faintly streaked and smudged brown, heaviest across lower breast; sides, flanks, belly and under-tail-coverts dull whitish, strongly tinged grey to greyish-brown; iris dark brown; bill dark brownish-grey, lower mandible often paler; legs dark grey. Sexes similar. Immature is more brownish than adult overall, especially below, and with no white wing spot. Voice. Noisy. Often gives loud, sharp "chewp" or "chuck", sometimes extended into a chatter of varying length, "chi-chi-chit"; also "tsweep, tsweep", which may be a song. Also a soft short twitter, and thin sigh like heavy exhalation.
Habitat. Undisturbed humid pre-montane and montane forest, also second growth, palm forests, thickets and coffee plantations at lower elevations. Recorded from c. 200 m upwards to tops of mountains, at c. 1330 m. Roosts communally in palms or bamboo clumps.
Food and Feeding. Wide range of food items, including arthropods and fruits; noted as eating *Cecropia* and palm fruits. Stomach contents have included orthopterans, weevils (Curculionidae), spiders (Araneae), moths and caterpillars (Lepidoptera), lizards, frogs, fruit, and a few hard grass seeds. Except when nesting, usually found in loose groups up to twelve or more individuals, mostly keeping well hidden in dense foliage when foraging; such groups often the dominant species in mixed flocks, which may contain up to twelve other species (including many North America migrants). Forages from canopy down to forest understorey, often rather high up. Moves and flutters along twigs, examines leaves and undersides of limbs. Seldom flies far, but flight strong and undulating.
Breeding. Season Jan–Aug. Few nests reported. Open, cup-shaped nest, loosely woven from feathers and grass, placed at low to moderate height in small tree; three reported nests were 2–10 m above ground and far out on a tree limb. Clutch 2–3 eggs, cream-coloured, heavily speckled brown. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Puerto Rico and the Virgin Islands EBA. Locally common. Common in many (but not all) of Puerto Rico's higher mountain forests. Occurs in Luquillo Mts, the W mountains around Maricao, including adjacent coffee plantations, and at one protected site, Carite-Guavate State Forest. Present also in El Yunque National Forest, and can be found along Puerto Rico Road 191 above the El Portal Rainforest Center. Occurs locally in disturbed second-growth forest at middle-level elevations near Cidra. Curiously, is absent in vicinity of Toro Negro, in heart of Central Mts, even though much suitable habitat appears to exist there. Is now absent also from haystack-hills region, although formerly occurred there. Within its restricted range, commoner at higher elevations, where more suitable habitat exists, and somewhat local at middle elevations; not found in lowlands. During 19th century this species was known only from a few higher-elevation sites, its decline apparently associated with near-complete deforestation of the island during that period. More recently, it has expanded into other suitable habitats and is apparently more numerous now than in recent past.

Genus *CHLOROSPINGUS* Cabanis, 1851

243. **Common Bush-tanager**

Chlorospingus ophthalmicus

French: Chlorospin des buissons **German**: Finkenbuschtangare **Spanish**: Clorospingo Común
Other common names: Brown-headed Bush-tanager; Dotted Bush-tanager (*punctulatus*); Yellow-breasted Bush-tanager ("*flavopectus* group"); Buff-breasted Bush-tanager (*cinereocephalus*)

Taxonomy. *Arremon ophthalmicus* du Bus de Gisignies, 1847, Jalapa, Veracruz, Mexico.
Recent molecular-genetic studies indicate that this genus and *Nesospingus*, *Spindalis* and *Phaenicophilus* form a monophyletic clade that is sister to several New World warbler (Parulidae) genera (including *Dendroica*, *Basileuterus* and *Vermivora*), and are not closely related to other genera of present family. More recent evidence suggests that *Chlorospingus* is closest to genus *Arremonops* in family Emberizidae. This species forms a monophyletic group with *C. tacarcunae* and *C. inornatus*; has been regarded as conspecific with former. Subspecific taxonomy complex and not fully understood; some races at least as distinct as are several other taxa in genus that are currently regarded as full species; DNA data reveal five major clades among Mexican populations alone, as supported by morphological analyses, but vocal information and equivalent data from S populations have not yet been analysed. Race *punctulatus* has sometimes been treated as a full species, as also have *cinereocephalus*, and the "*flavopectus* group" (also including *trudis*, *nigriceps*, *exitelus*, *macarenae* and *phaeocephalus*). Numerous racial limits poorly defined, and taxonomy of the species, as a whole, in need of review. Proposed race *persimilis* (described from R Guajolote, SW of San Miguel Suchixtepec, in Oaxaca, Mexico) is regarded as synonymous with *albifrons*. Twenty-six subspecies currently recognized.
Subspecies and Distribution.
C. o. ophthalmicus (du Bus de Gisignies, 1847) – Atlantic slope of E Mexico (SE San Luis Potosí and W Veracruz S to NE Oaxaca).
C. o. wetmorei Lowery & Newman, 1949 – Sierra de Tuxtla (E Veracruz), in S Mexico.
C. o. albifrons Salvin & Godman, 1889 – Sierra Madre del Sur (Guerrero and Oaxaca), in S Mexico.
C. o. dwighti Underdown, 1931 – Caribbean slope in S Mexico (Chiapas) and Guatemala.
C. o. postocularis Cabanis, 1866 – Pacific slope in S Mexico (Chiapas) and Guatemala.
C. o. honduratius Berlepsch, 1912 – El Salvador and Honduras.
C. o. regionalis Bangs, 1906 – Nicaragua and E Costa Rica.
C. o. novicius Bangs, 1902 – SW Costa Rica and W Panama (Chiriquí).
C. o. punctulatus P. L. Sclater & Salvin, 1869 – W Panama (Veraguas E to Panamá).
C. o. ponsi Phelps, Sr & Phelps, Jr, 1952 – NW Venezuela (E slope of Sierra de Perijá).
C. o. falconensis Phelps, Sr & Gilliard, 1941 – N Venezuela (Sierra de San Luis, in Falcón, and Sierra de Aroa, in Yaracuy).
C. o. venezuelanus Berlepsch, 1893 – W slope of Venezuelan Andes (from Lara S to Táchira).
C. o. jacqueti Hellmayr, 1921 – N & SW Venezuela (Miranda and E slope of Andes from Lara S to Táchira) and W slope of E Andes (Norte de Santander) in Colombia.
C. o. eminens J. T. Zimmer, 1946 – E slope of E Andes in Colombia (S part of Norte de Santander and Boyacá).
C. o. flavopectus (Lafresnaye, 1840) – W slope of E Andes in Colombia from Santander S to vicinity of Bogotá.
C. o. trudis Olson, 1983 – W slope of E Andes at La Pica (between San Andrés and Málaga), in E Santander (Colombia).
C. o. nigriceps Chapman, 1912 – Colombia on E slope of W Andes at N end, both slopes of C Andes (S of *exitelus*), and W slope of E Andes (S of *flavopectus* and *trudis* to upper end of Magdalena Valley).
C. o. exitelus Olson, 1983 – both slopes of N end of C Andes in Antioquia (Colombia).
C. o. macarenae J. T. Zimmer, 1947 – Macarena Mts, in S Meta (Colombia).
C. o. phaeocephalus P. L. Sclater & Salvin, 1877 – both slopes of Andes in Ecuador.
C. o. hiaticolus O'Neill & T.A. Parker, 1981 – Andes of N Peru (S to Pasco).
C. o. cinereocephalus Taczanowski, 1874 – Andes of C Peru (Junin, probably also N Cuzco).
C. o. peruvianus Carriker, 1933 – Andes of S Peru (Cuzco and Puno).
C. o. bolivianus Hellmayr, 1921 – Andes of N Bolivia (Cordillera de La Paz S to N end of Cordillera de Cochabamba).
C. o. fulvigularis Berlepsch, 1901 – Andes of C Bolivia (S Cordillera de Cochabamba).
C. o. argentinus Hellmayr, 1921 – Andes of C Bolivia (headwaters of R Mizque) S to N Argentina (Jujuy, Salta and Tucumán).

Descriptive notes. 13–14 cm; 13–18 g (*bolivianus*), 16–22·5 g (*hiaticolus*), 15·1–18·5 g (*jacqueti*), 19·1–28·4 g (*flavopectus*). Variable bush-tanager, generally olive above, with grey to occasionally blackish head, grey to white underparts, with throat pale or dark and plain or well marked, and usually with distinct breastband. Nominate race has head brownish, prominent white eyering and postocular stripe, dark brown patch on ear-coverts, and some whitish on loral area; otherwise yellowish-olive above, including wing and tail; throat and underparts whitish, strongly tinged pale yellow on chest, sides, flanks and undertail-coverts, sometimes dark flecks on side of throat; iris brown; bill dusky grey; legs dark grey. Sexes similar. Immature is generally browner above, dingier and darker below, and with duller, less pronounced postocular spot. Races differ in plumage colour (especially head, throat and pectoral band), iris colour, presence or absence of white postocular mark, and other markings: *albifrons* differs from nominate in having a more sienna-brown head, with buffy-white supraloral area, extensive loral area blackish, throat light cinnamon-buff, often with dark strokes forming a malar stripe, and darker yellow-ochre pectoral band; *postocularis* is similar to nominate, but crown greyish, lores dusky, postocular stripe shorter, has indistinct dusky lateral crownstripe, dusky lores and whitish throat; *dwighti* differs from nominate in having crown slate-grey, becoming blackish laterally, producing two rather broad but not sharply defined lateral stripes, also back somewhat darker and more citrine (less greenish), middle of belly more greyish; *honduratius* is like *postocularis*, but crown uniformly greyish (no dusky lateral crownstripe); *regionalis* is like nominate, but head greyish with browner tinge on forecrown, rear ear-coverts paler, throat with dull brownish mottling; *novicius* is like nominate, but head and loral area dusky brown, malar area buff, and prominent white postocular spot partly surrounding eye (but no stripe), and whitish throat; *punctulatus* differs from nominate in having head very dark blackish-brown, olive of upperparts tinged rufescent (not yellowish), and chestband darker yellow; *eminens* has prominent white postocular spot and almost clean white throat; *exitelus* lacks postocular spot; *falconensis* has white postocular spot, iris pale grey; *flavopectus* has greyish head, dark iris, almost clean white throat (no spots), and no postocular spot; *jacqueti* has whitish iris and prominent white postocular spot; *macarenae* is closest to *flavopectus*, but crown slightly darker brownish-grey, throat darker buff and more spotted, chest and sides darker yellow, and whitish belly; *nigriceps* has dusky head, white iris and no white postocular; *phaeocephalus* is one of dingiest races, has pale yellowish to orangish iris, lightly dotted buff throat, and no postocular; *ponsi* has white postocular; *trudis* has almost unspotted white throat and no postocular spot; *venezuelanus* has sooty-black head, whitish iris, white postocular, and whitish throat thickly dotted black; *cinereocephalus* has dark brownish-grey crown, yellowish to pale grey iris, no white postocular, and chestband yellow-buff (not yellow); *peruvianus* has grey head, pale iris, no white postocular, buff-white throat with spots, and chest and sides pale yellow; *bolivianus* has blackish head, white iris, white postocular, dusky cheek, dingy throat and prominent buff chestband; *argentinus* is like previous, but has dingy brownish (not dusky) crown and side of head, dark iris, small white postocular, and deeper ochraceous pectoral band; *fulvigularis* has both throat and, especially, chest strongly washed ochraceous, iris variable, some pale-eyed and others dark-eyed. Voice. Call notes include buzzy "tzit" repeated over and over, longer trilled "ts'i'i'i'i'i'i't" and "chup". Dawn songs vary considerably over range: in Costa Rica repeats a piercing "seeek" or "tseer" for minutes on end from high perch, sometimes inserting a twitter; in Venezuela (races *jacqueti* and *venezuelanus*) a long, monotonic "chup, chup, chup...", 1 note per second for up to several minutes; dawn songs of "*flavopectus* group" (in Colombia) and of *cinereocephalus* (in Peru) more complex, typically a series of "chit" notes of increasing volume, then an accelerating series of higher-pitched "chid-it" notes and ending with lower-pitched churring "trrrrrrrrrrr" trill as volume diminishes. Dawn songs of S races (e.g. *phaeocephalus* and *hiaticolus*) also are complex, and may change from single notes to double notes, accelerate, or include churring trills. In most areas true song appears to be confined mainly to the dawn period. Alarm or aggressive notes include "tuck" or "sreeee"; during foraging often rather vocal, giving variety of sharp notes, e.g. "tsip, tseep", and a sharp "tsweek" that rushes into a rapid, descending twitter; also a rattling "tsrrrr" and a staccato "cut" in interactions.
Habitat. Humid montane forest and forest borders, especially mossy, epiphyte-laden forest, tall second growth and bushy clearings and pastures in forested areas. Recorded mostly at 1000–2600 m, locally higher and lower; in N of range c. 400–2300 m, but reported to 3500 m in Mexico; to 3000 m in Guatemala, Venezuela and Bolivia; in Andes generally at higher average elevations than in Middle America, mostly 1000–2300 m in Venezuela, 1000–2700 m in Colombia, 1500–2500 m on E slope and 700–1450 m on W slope in Ecuador, and 1100–2650 m in Peru. In Colombia, race *trudis* found at 2800 m.
Food and Feeding. Small berries and fruit, in Costa Rica including fruits of Ericaceae, Melastomataceae and Gesneriaceae; also small arthropods. Of 49 stomachs examined, one contained only vegetable matter and 29 only animal matter, and 19 contained both; contents included beetles (Coleoptera), other insects, seeds, and fruit juice. In pairs when breeding, otherwise in families or groups of up to about ten individuals that are often joined by other understorey species; also, readily joins temporary feeding associations of birds at fruiting trees and shrubs. Active and restless, frequently flicks wings and tail when foraging. Forages alertly from about eye level up to subcanopy, but often fairly low, especially inside forest, where typically hops outwards along branches into leafy terminal sections. Peers, pecks and perch-gleans on bare or mossy substrates, epiphytes and leaves, and squeezes bases of corollas for nectar; occasionally drops to ground or hangs downwards or upside-down to gain access to curled leaves, also flutters after or chases fleeing insects. Gulps small berries and fruit, mashes tough-skinned fruits, or pecks at large ones.
Breeding. Season Apr–Jun in Mexico, Mar–Jun in Costa Rica (up to two broods or two attempts), in breeding condition Mar to mid-Jul in W Panama, eight birds in breeding condition Apr–Jun in Colombia, and four in breeding condition in Oct and breeding reported in Nov in S Peru (Puno); in general follows pattern typical of many tropical species, most breeding in first half of year in N part of range, more dispersed or bimodal near equator, and predominantly in latter half of year S of equator. Bulky nest of moss, grass, leaves and rootlets, lined with fine fibres and fragments of vegetation, well hidden on bank at ground level or to 16 m up in moss or epiphytes in tree; if second nesting attempted, new nest built. Clutch normally 2 eggs, infrequently 3 (mainly in N part of range), sometimes only 1 (in S of range), dull white marked with shades of brown, cinnamon and red, sometimes concentrated at large end; incubation by female, period c. 14 days; chicks fed by both adults, nestling period c. 13–14 days.
Movements. Resident.
Status and Conservation. Not globally threatened. Common virtually throughout its wide range. Deforestation a threat locally, but this species survives even in bushy second growth and along narrow forest corridors.

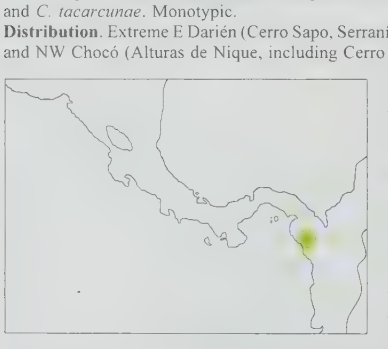
244. **Tacarcuna Bush-tanager**

Chlorospingus tacarcunae

French: Chlorospin du Tacarcuna **Spanish**: Clorospingo del Tacarcuna
German: Tacarcunabuschtangare

On following pages: 245. Pirre Bush-tanager (*Chlorospingus inornatus*); 246. Dusky Bush-tanager (*Chlorospingus semifuscus*); 247. Sooty-capped Bush-tanager (*Chlorospingus pileatus*); 248. Short-billed Bush-tanager (*Chlorospingus parvirostris*); 249. Yellow-throated Bush-tanager (*Chlorospingus flavigularis*); 250. Yellow-green Bush-tanager (*Chlorospingus flavovirens*); 251. Ashy-throated Bush-tanager (*Chlorospingus canigularis*).

Taxonomy. *Chlorospingus tacarcunae* Griscom, 1924, Mount Tacarcuna, east slope, eastern Panama.
Recent molecular-genetic studies indicate that this genus and *Nesospingus*, *Spindalis* and *Phaenicophilus* form a monophyletic clade that is sister to several New World warbler (Parulidae) genera (including *Dendroica*, *Basileuterus* and *Vermivora*), and are not closely related to other genera of present family. More recent evidence suggests that *Chlorospingus* is closest to genus *Arremonops* in family Emberizidae. This species forms a monophyletic group with *C. ophthalmicus* and *C. inornatus*; has been regarded as conspecific with former. Was formerly treated sometimes as conspecific with *C. flavigularis*. Monotypic.
Distribution. Cerros Jefe and Azul (C Panamá), Cerro Brewster (W San Blas) and Cerros Mali and Tacarcuna (Darién), in Panama, and slopes of Cerro Tacarcuna in adjacent Colombia (NW Chocó).



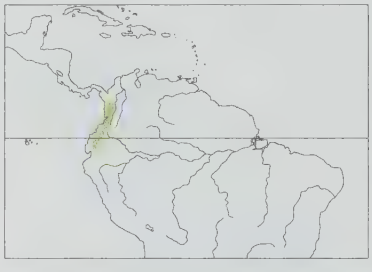
Descriptive notes. 13 cm; male 18·2–20 g, one female 17·8 g. Head and upperparts, including upperwing-coverts, olive, bend of wing pale yellow; flight-feathers dusky, outer feathers edged greenish-yellow, secondaries edged olive, tertials dark olive-green; tail dusky, tinged olive and edged olive-green; throat yellow, becoming dull yellow on breast and yellowish-white on centre of lower breast and belly; sides, flanks and undertail-coverts strongly tinged olive, underwing-coverts white; iris whitish to pale orange-yellow; bill blackish; legs brownish-grey, feet grey. Sexes similar. Immature is similar to adult, but duller, and with dark iris. Voice. Most distinctive call, during foraging, a penetrating and forceful "tseeeu!", descending slightly; other, less distinctive call notes represent minor variations on this dominant call. No dawn song recorded.
Habitat. Humid forest and forest borders, including low, wet elfin forest in mountains; at 850–1000 m in C Panama and 1000–1500 m in E Panama.
Food and Feeding. Stomach contents include small green caterpillars and chitinous insect parts. Forages in pairs or small groups, often with other species in small understorey mixed flocks; seems to form the dominant (nuclear) species in some flocks. Forages from understorey up to subcanopy or even canopy levels.
Breeding. Female carrying nest material in Feb (Darién) and pair building nest in mid-Apr in Panamá (Cerro Jefe, 859 m). On Cerro Jefe, both members of pair carried material, including pale strips of grass or palm leaves, to base of bromeliad; nest c. 6·5 m up in cavity formed by bromeliad on top of limb. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Darién Highlands EBA. Fairly common very locally in E Panama. Deforestation a threat within the range of the two small W populations; settlement and deforestation has not yet reached E Panama population. May occur in Darién National Park, in Panama, and in or close to Los Katíos National Park, in Colombia, although area near latter park is well protected.
Bibliography. Bradley (2005), Christian (2001), Davis (1972), Hellmayr (1936), Hilty & Brown (1986), Isler & Isler (1999), Restall *et al.* (2006), Ridgely & Gwynne (1989), Salaman *et al.* (2008), Wetmore *et al.* (1984).

245. Pirre Bush-tanager

Chlorospingus inornatus

French: Chlorospin du Pirré **Spanish**: Clorospingo del Pirre
German: Schwarzwangen-Buschtangare
Other common names: Mount Pirr(i)e Bush-tanager

Taxonomy. *Hylospingus inornatus* Nelson, 1912, Mount Pirre, 5200 feet [c. 1580 m], eastern Panama.
Recent molecular-genetic studies indicate that this genus and *Nesospingus*, *Spindalis* and *Phaenicophilus* form a monophyletic clade that is sister to several New World warbler (Parulidae) genera (including *Dendroica*, *Basileuterus* and *Vermivora*), and are not closely related to other genera of present family. More recent evidence suggests that *Chlorospingus* is closest to genus *Arremonops* in family Emberizidae. This species forms a monophyletic group with *C. ophthalmicus* and *C. tacarcunae*. Monotypic.
Distribution. Extreme E Darién (Cerro Sapo, Serranía de Jungurudó and Cerro Pirre), in E Panama, and NW Chocó (Alturas de Nique, including Cerro Nique), in NW Colombia.



Descriptive notes. 15 cm; 20–36 g. Crown and side of head to below eye are dark grey, contrasting with olive-green of upperparts, including upperwing-coverts; flight-feathers dusky, outer feathers edged dark green (basal half of outer web), inner ones more broadly edged olive, tertials mostly olive; central tail feathers dusky, outer ones with progressively more olive on edges and webs; throat dull yellowish-white, becoming darker olive-yellow on breast, sides and flanks; centre of lower breast, belly and undertail-coverts clear yellow; iris whitish to pale orange-yellow; bill black; legs slaty-grey to fuscous black. Sexes similar. Juvenile undescribed. Voice. Gives three different thin, buzzy, high-pitched notes, including "spéétza", a simple "tsip" and "chuweet?", any one of them uttered singly, repeated up to four times (most often), or the three given in various combinations. Dawn song unrecorded.
Habitat. Canopy and borders of humid forest and stunted montane woodland; favours vine tangles and bamboo in stunted woodland. Up to at least 1700 m in Panama; recorded at 780–1560 m in Colombia.
Food and Feeding. Fruits and small arthropods. Of seven stomachs examined, three contained only vegetable matter and two only animal matter and four contained both; contents included fruit, larvae, and insect remains. Usually found in groups of 3–6 individuals, with mixed-species flocks or independently of them. Forages mostly from middle to upper levels of trees and bushes, and frequently in canopy of montane forest. Searches for insects along smaller branches and in foliage. Gleans from leaves and tree-fern fronds, and picks at mosses on branches, and noted as hanging suspended from lower side of twigs.
Breeding. No information.
Movements. No information; local movements unlikely.
Status and Conservation. Not globally threatened. Restricted-range species: present in Darién Highlands EBA. Common at higher elevations, where it is the only bush-tanager within its limited range; e.g. fairly common above c. 1200 m on Cerro Pirre. Recently found to be common in Serranía de Jungurudó, a site that represents a range extension for this species in E Panama. Despite small global range, there are no current threats from deforestation. Occurs within remote and largely inaccessible Darién National Park (Panama). Threats to this region are at present minimal, but the park, because of its remoteness, largely lacks effective protection.
Bibliography. Angehr *et al.* (2004), Barbour & Brooks (1923), Bond & Meyer de Schauensee (1944), Davis (1972), Griscom (1929), Hilty & Brown (1986), Restall *et al.* (2006), Ridgely & Gwynne (1989), Robbins *et al.* (1985), Stattersfield *et al.* (1998), Wetmore *et al.* (1984).

246. Dusky Bush-tanager

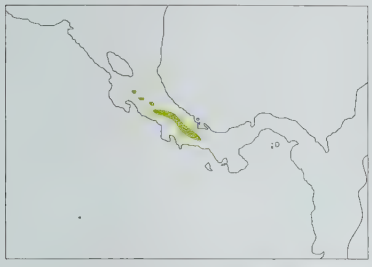
Chlorospingus semifuscus

French: Chlorospin ombré **German**: Graubrust-Buschtangare **Spanish**: Clorospingo Oscuro
Other common names: Dusky-bellied Bush-tanager

Taxonomy. *Chlorospingus semifuscus* P. L. Sclater and Salvin, 1873, near Quito, Ecuador.
Recent molecular-genetic studies indicate that this genus and *Nesospingus*, *Spindalis* and *Phaenicophilus* form a monophyletic clade that is sister to several New World warbler (Parulidae) genera (including *Dendroica*, *Basileuterus* and *Vermivora*), and are not closely related to other genera of present family. More recent evidence suggests that *Chlorospingus* is closest to genus *Arremonops* in family Emberizidae. Two subspecies recognized.
Subspecies and Distribution.
C. s. livingstoni J. Bond & Meyer de Schauensee, 1940 – W slope of W Andes of Colombia from S Chocó (upper R San Juan) S to Cauca (Munchique area).
C. s. semifuscus P. L. Sclater & Salvin, 1873 – SW Colombia (Pacific slope in Nariño) and W slope in Ecuador (S to W Cotopaxi).

Descriptive notes. 14–15 cm; 17–23 g. Drab, undistinguished bush-tanager. Nominate race has crown and side of head dark grey, tiny white postocular spot sometimes present; upperparts, including upperwing-coverts, dark olive; flight-feathers dusky, edged yellowish-olive, tertials and tail mostly dark olive; throat and underparts mainly brownish-grey (paler than crown), paler on centre of belly, sometimes with ochraceous-olive wash forming a diffuse pectoral band, flanks and undertail-coverts tinged olive; iris light reddish-brown to intense brownish-red; bill blackish; legs dark grey. Sexes similar. Juvenile is duller than adult, with faint grey streaks on belly. Race *livingstoni* is overall darker than nominate, more smoky grey (less brownish) on head and smoky olive on upperparts, greyer (less brownish-tinged) below, iris yellowish-white. Voice. Dawn song a series of high "tsit" notes changing to "tsit-it" notes and gradually into slightly buzzy trill; described also as a series of high-pitched notes, almost like those of a hummingbird (Trochilidae), that gradually speed up and gain strength, becoming quite "spanking" before ending in dry sputter. In SW Nariño (Colombia) groups of males formed dense linear song leks, regularly spaced along ridges, from which they sang at dawn and again in late afternoon during most of year, with peak May–Aug. Call an extremely high-pitched "chip", often repeated, and a thin penetrating trill.
Habitat. Wet montane forest, especially wet, foggy and epiphyte-laden forest; stays mainly inside forest, but visits fruiting shrubs at forest borders. Recorded at 900–2500 m in Colombia (W Cauca) and mostly 1200–2300 m in Ecuador. Typically, more at lower levels and in interior of forest than *C. ophthalmicus* and *C. canigularis*.
Food and Feeding. Insects, and small fruits and berries. Forages in pairs and in small groups, often with mixed-species flocks as well as independently of them; participation in flocks occurs throughout year, but reduced during peak singing period and during singing hours. Forages in active alert manner, hopping along smaller branches and perch-gleaning, also taking small fruits and berries, much like other members of genus.
Breeding. Nest-building in Apr, nest with chicks in Jun, and stub-tailed fledglings seen with adults in Apr (four separate pairs) and Jun (two pairs) in SW Nariño, in Colombia. Groups of singing males found to occupy small circular territories at ridgetop song assemblies, sites usually reoccupied in subsequent years by same males; fruit resources may permit males to remain on territories for long periods, and nest-sites believed to be far from the ridgetop assemblies. Partners apparently form pair-bond and male participates at least in nest-site selection and feeding of young, suggesting that a system of linear singing assemblies is superimposed upon a social system that is otherwise typical of genus. At La Planada Nature Reserve (SW Nariño), female carried grass and dry bamboo leaves to a nest 7·5 m up and c. 2 m from trunk, cup-nest embedded in moss and epiphytes. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Chocó EBA. Fairly common to common throughout rather narrow elevational zone. Generally more numerous at higher elevations. In Ecuador, unconfirmed sightings farther S, in El Oro, require corroboration. Can be found in Farallones de Cali and Munchique National Parks and La Planada and Tambito Nature Reserves, in Colombia. Deforestation and forest fragmentation is accelerating throughout its small global range.
Bibliography. Best *et al.* (1993), Bohórquez & Stiles (2002), Donegan & Dávalos (1999), Dunning (1982), Echeverry-Galvis & Córdoba-Córdoba (2007), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Moore *et al.* (1999), Orejuela & Cantillo (1990), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Strewe (2001a).

247. Sooty-capped Bush-tanager



Chlorospingus pileatus

French: Chlorospin à sourcils brisés **Spanish**: Clorospingo Cejiblanco
German: Weißbrauen-Buschtangare
Other common names: Pileated Bush-tanager; Volcano Bush-tanager ("*zeledoni*")

Taxonomy. *Chlorospingus pileatus* Salvin, 1865, Volcán Irazú, Costa Rica.
Recent molecular-genetic studies indicate that this genus and *Nesospingus*, *Spindalis* and *Phaenicophilus* form a monophyletic clade that is sister to several New World warbler (Parulidae) genera (including *Dendroica*, *Basileuterus* and *Vermivora*), and are not closely related to other genera of present family. More recent evidence suggests that *Chlorospingus* is closest to genus

Arremonops in family Emberizidae. The form "*zeledoni*", originally described as a separate species, now considered to be only a colour morph of present species; known only from Volcán Irazú and Volcán Turrialba, in Costa Rica. Birds from Cerro Flores, in E Chiriquí (Panama), supposedly with yellower underparts and whiter central abdomen, described as race *diversus*, but appear inseparable from those in rest of species' range. Monotypic.

Distribution. Mountains from C Costa Rica S to W Panama (Volcán de Chiriquí).

Descriptive notes. 14 cm; 16–24·1 g. Distinctive bush-tanager with head boldly striped black and white. Head is sooty black, with broad white lateral crownstripe beginning just in front of eye and extending to side of neck, often with offshoot towards eye of varying extent; upperparts, including upperwing-coverts, olive; flight-feathers dusky, edged olive-yellow, tertials more broadly edged olive-yellow; tail olive; throat whitish with numerous tiny black spots (inconspicuous), contrasting sharply with broad olive-yellow breastband, olive-yellow colour extending to sides, flanks and undertail-coverts; centre of lower breast and belly yellowish-white; individuals from volcano area of Irazú and Turrialba (in C Costa Rica) tend to be duller and greyer overall and lack yellow tinge on underparts ("*zeledoni*"); iris reddish-brown; bill blackish; legs dull brownish to lead-grey or fuscous black. Sexes similar. Juvenile is yellowish with blurry olive streaking below. Voice. Calls include high, thin, lisping "tsit" notes, sometimes in continuous stream or followed by "t-z-z-z-z-z-zit, chat-t-t-t-, zwee-zwee-zwee..." and so on; also a high, double "zit" or "zeet", and variety of high, scratchy notes such as "tsip" and "tseep"; also short chatter and a twitter. At dawn, sometimes more irregularly and briefly at other times, male sings scratchy, rapid "see-chur see-chur see-chur see see see-chur"; song described also as a pleasant, somewhat sibilant, fast "sit-sit swiee-d-d-d-d-d-d sit-a-wit", high-pitched, but final part slightly lower, mainly during breeding period.

Habitat. Mossy humid and wet montane and elfin forest and tall second growth, occasionally patches of woodland in pastures if near tall forest; also ranges locally into shrubby *páramo*. Recorded at c. 1500–2850 m, or up to tree-line; in Costa Rica, commonest above 2000 m in Cordillera de Talamanca and mainly above 1600 m in Cordillera de Tilarán.

Food and Feeding. Small arthropods; fruits, especially *Miconia*, *Fuchsia*, blackberries (*Rubus*) and Ericaceae. Found in pairs or in small loose flocks of up to about six individuals when breeding, at other times associates in larger groups, occasionally up to 20–40 birds; pairs, families or groups also joined by other species, especially Ruddy Woodcreeper (*Dendrocincla homochroa*), New World warblers (Parulidae) and other smaller species. Forages mostly from near ground to middle of canopy (c. 12 m up), most commonly at 3–6 m. When foraging, is restless and active, habitually flicking wings and tail, and sometimes remarkably confiding. Searches by hopping along mossy branches and up through dense shrubbery, poking and pecking in moss, lichens and bromeliads for food items; also tears at arboreal curled dead leaves.

Breeding. Season reported as Feb–Jul in Costa Rica. Defends a breeding territory. Possibly sometimes a co-operative breeder, several adults seen at single nest. Nest a soft, bulky cup of mosses, liverworts and beard lichen (*Usnea*), lined with fine grasses or fine, black rootlets, placed in crevice, atop a vertical bank, or under tuft of moss in dense low shrub, or in epiphytes on branch to 11 m up. Clutch 1–2 eggs, white, speckled and blotched with pinkish-brown, mostly at large end; no information on incubation and nestling periods; three or more adults may attend nestlings.

Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Common above c. 2000 m; fairly common down to 1600 m locally, e.g. Cordillera de Tilarán (Costa Rica). Deforestation is widespread within the notably small global range of this species.

Bibliography. Burns (1997a), Burns *et al.* (2002, 2003), Carriker (1910), Davis (1972), Garrigues & Dean (2007), Hartman (1955), Isler & Isler (1999), Johnson & Brush (1972), Moynihan (1962a, 1962c), Ridgely & Gwynne (1989), Skutch (1967a), Slud (1964), Stiles & Skutch (1989), Wetmore *et al.* (1984), Wolf (1976).

248. **Short-billed Bush-tanager**

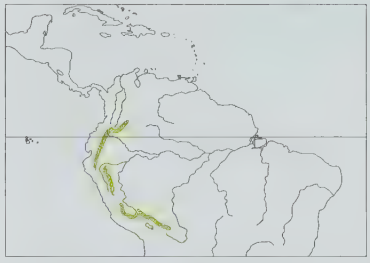
Chlorospingus parvirostris

French: Chlorospin à bec court **Spanish**: Clorospingo Bigotudo
German: Kurzschnabel-Buschtangare
Other common names: Yellow-whiskered Bush-tanager

Taxonomy. *Chlorospingus flavigularis parvirostris* Chapman, 1901, Santo Domingo, Marcapata, south-eastern Peru.

Recent molecular-genetic studies indicate that this genus and *Nesospingus*, *Spindalis* and *Phaenicophilus* form a monophyletic clade that is sister to several New World warbler (Parulidae) genera (including *Dendroica*, *Basileuterus* and *Vermivora*), and are not closely related to other genera of present family. More recent evidence suggests that *Chlorospingus* is closest to genus *Arremonops* in family Emberizidae. This species was originally considered a race of *C. flavigularis*, but subsequently separated on basis of size, plumage and elevational distribution. Three subspecies recognized.

Subspecies and Distribution.



C. p. huallagae Carriker, 1933 – E slope of E Andes from Colombia (Cundinamarca and Meta) S through Ecuador to NW Peru (La Libertad).

C. p. medianus J. T. Zimmer, 1947 – E slope of Andes in C Peru (Junín and Urubamba regions).

C. p. parvirostris Chapman, 1901 – E slope of Andes in SE Peru and adjacent Bolivia.

Descriptive notes. 14 cm; 17·5–28·5 g. Drab bush-tanager with yellow sweeping out on each side of throat. Nominate race has crown, side of head and upperparts, including upperwing-coverts and tail, olive-green, flight-feathers dusky, edged olive, tertials more broadly edged olive; side of throat bright yellow, flaring back and slightly upward onto side of neck ("whiskers") and sometimes raised in slight tuft below ear-coverts; rather uniformly grey below, centre of throat somewhat paler; iris yellowish-white to light grey; bill dusky; legs dark grey. Sexes similar. Juvenile undescribed. Race *huallagae* is slightly duller and browner than nominate, has side of throat mustard-yellow (less bright than nominate), centre of throat, breast and belly mostly smoky brownish-grey, undertail-coverts olive-yellow; *medianus* is intermediate between previous and nominate. Voice. Call in Colombia an incessant "tsip"; in Ecuador "tsrreet"; in Peru a high, vibrating "seeep", sometimes preceded by thin "tsip". Dawn song apparently unrecorded.

Habitat. Humid and wet montane forest and forest borders, especially in mossy, epiphyte-laden forest; in E Ecuador and E Peru shows some affinity for vegetation bordering streams. At c. 1400–2100 m (once to 2500 m) in Colombia, 1100–2250 m in Ecuador, and 1100–2750 m in Peru; throughout range occurs mainly at higher elevations than those at which *C. flavigularis* found.

Food and Feeding. Arthropods, and small fruits and berries. Of nine stomachs examined, one contained only vegetable matter and five only animal matter, and three contained both; contents included beetles (Coleoptera) and other insects, fruit and seeds. Found in pairs and in small groups of up to eight individuals, typically foraging with mixed-species flocks, also sometimes away from them. Actively and restlessly hops along bare or mossy branches and twigs, and peers and pecks food items. Foraging behaviour much like that of congeners.

Breeding. Breeding period apparently starts in dry season, but extends into Jan–Jun (rainiest months); seven nests (six with eggs) found in Sept–Feb on E slope in Ecuador; dependent fledgling seen in May. Large shallow cup-nest 15 cm wide, 4 cm deep, internal diameter 9·5 cm, thickly lined with tree-fern scales, placed 0·4–2·5 m up on mossy rock ledge bordering stream or supported by vegetation resting against cliff face; five active nests were built on top of old nests, suggesting high nest-site fidelity. No definite data on clutch size; eggs pale salmon to buff-white with pale red-brown and lavender flecking and speckling, heaviest at larger end, average dimensions 22·3 × 16·1 mm. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Fairly common to common in Colombia and in SE Peru (Cuzco); possibly less numerous along E slope in Ecuador, where reportedly fairly common mainly in S region (most records in Ecuador are relatively modern). Distribution possibly discontinuous. Should occur in Cueva de los Guácharos National Park (Colombia), possibly Podocarpus National Park (S Ecuador), Manu National Park (Peru), and probably Madidi National Park (Bolivia). Within its range considerable intact forest exists, but habitat under assault in many areas from deforestation and human settlement.

Bibliography. Brumfield & Maillard (2007), Chapman (1917, 1926), Clements & Shany (2001), Greeney (2005), Hellmayr (1936), Hilty & Brown (1986), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Walker (2001), Zimmer (1947b).

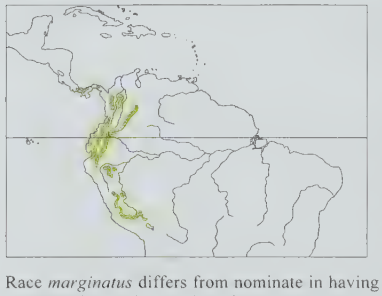
249. **Yellow-throated Bush-tanager**

Chlorospingus flavigularis

French: Chlorospin à gorge jaune **Spanish**: Clorospingo Goliamarillo
German: Gelbkehl-Buschtangare
Other common names: Drab-breasted Bush-tanager (*hypophaeus*)

Taxonomy. *Pipilopsis flavigularis* P. L. Sclater, 1852, "Bogotá", Colombia.

Recent molecular-genetic studies indicate that this genus and *Nesospingus*, *Spindalis* and *Phaenicophilus* form a monophyletic clade that is sister to several New World warbler (Parulidae) genera (including *Dendroica*, *Basileuterus* and *Vermivora*), and are not closely related to other genera of present family. More recent evidence suggests that *Chlorospingus* is closest to genus *Arremonops* in family Emberizidae. Central American race of this species, *hypophaeus*, geographically isolated and differing from others in plumage, may prove to be a separate species; study required. Three subspecies recognized.



Subspecies and Distribution.

C. f. hypophaeus P. L. Sclater & Salvin, 1868 – W Panama from Volcán Barú (Volcán de Chiriquí) E to C Veraguas.

C. f. marginatus Chapman, 1914 – W slope of W Andes in Colombia (from Valle del Cauca) S to SW Ecuador (El Oro).

C. f. flavigularis (P. L. Sclater, 1852) – Andes of Colombia (N end of W range in Córdoba and Antioquia, both slopes of C range in Antioquia, and E slope of E range S from Boyacá) S on E slope to Ecuador and Peru (S to Puno).

Also, a population of unknown race (either *marginatus* or nominate) on Cerro Tatamá, on Valle del Cauca–Risaralda–Chocó border, in Colombia.

Descriptive notes. 13 cm, 15–20 g (*hypophaeus*); 15 cm, 21·5–31 g (*marginatus* and nominate). Rather plain bush-tanager, dull yellow throat often not particularly conspicuous. Nominate race has lores grey, crown, side of head and upperparts, including upperwing-coverts and tail, yellowish-olive; flight-feathers dusky, edged dull yellow; entire throat yellow, rest of underparts light grey, palest on central belly, with olive tinge on flanks and undertail-coverts; iris hazel; upper mandible mostly dusky, lower mandible paler greyish with dusky tip; legs dark grey. Sexes are similar. Juvenile apparently undescribed. Race *marginatus* differs from nominate in having yellow confined mostly to side of throat (but not sweeping back onto side of neck), and centre of throat and underparts duller brownish-tinged grey, iris grey; *hypophaeus* is overall duller, brownish-olive above, dingier below, but yellow of throat more ochraceous than in nominate, iris dark. Voice. Gives high "chip" notes constantly during foraging; flock-members utter "chip" and "seet" notes. Dawn song in W Colombia a short, weak and high-pitched "chit, twee-twee-twee-twit" in steady series of more or less alternating notes; in Ecuador (*marginatus*) a monotonous series of weak high "tsit" notes at c. 2 per second; dawn song in Peru (nominate) a loud, musical "wheet-chew-wheet-wheet-wheet-chew" or shorter "chip-weet-weet-weet".

Habitat. Inhabits humid to wet mossy forest, borders of forest and various stages of second-growth woodland; occasionally in scattered trees in small pastures surrounded by forest. Mostly in foothills and lower slopes of Andes, and generally below elevational range of other members of its genus, although some local overlap occurs. Race *hypophaeus* recorded at 250–900 m; *marginatus* c. 300–1400 m in W Colombia and W Ecuador; nominate recorded mostly at 700–1800 m (occasionally to 2100 m) in Ecuador and 750–1800 m in Peru.

Food and Feeding. Berries and fruit, also insects. Of 567 observations of feeding in W Colombia (Anchicayá Valley, in Valle del Cauca), 64% involved birds eating fruit, 29% insect-searching, and

7% at flowers (precise food source at flowers undetermined); 28 species of fruit taken, 90% of which were melastomes, especially *Miconia* (which constituted 78% of all fruit records); also ate buds and flower parts from melastomes. Usually in pairs or small groups that join (or are joined by) other species in mixed flocks. Forages from near ground to middle of canopy. In W Colombia median foraging height was c. 6 m, and only c. 25% of observations above 12 m; in Peru mostly at 1–10 m, occasionally ascending to canopy, especially in fruiting trees. Flutters and hops actively and energetically along smaller branches, and perch-gleans insects and fruit; sometimes remarkably unsuspicious. Usually perched upright on twigs or branches to take fruit or flowers (68% of 157 observations), frequently snatched berries in short sallies (27% of records), and occasionally hung downwards to grasp fruit. Swallows small fruits whole; squeezed or pecked at larger ones. Searched for insects by hopping along mossy and bare branches of various sizes, including large (0·3 m diameter) slanting trunks, stopping to cock head to peer at substrate; also foraged in vine tangles and in thickets. Peered and picked prey from branches and leaves about equally, taking insects from both sides of leaves, and reached out to pluck prey off bromeliads, vines, buds and spider webs. Frequently sallied to leaves, branches and air (33% of 76 observations).

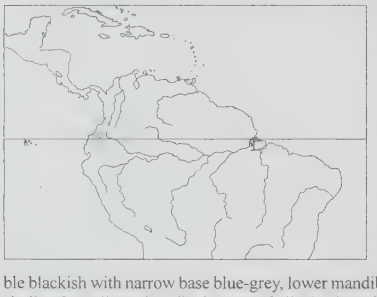
Breeding. In Colombia, nest found in Feb, young being fed in Apr, and nest-building in Sept in Anchicayá Valley (in Valle del Cauca), and seven birds in breeding condition in Jun at N end of C Andes and one in Oct in E Boyacá. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Fairly common to common along humid montane slopes of Andes; possibly less common in Panama. Numerous protected sites exist within the long but narrow range of this species, among them La Amistad National Park (Panama), Farallones de Cali and Cueva de los Guácharos National Parks and Tambito Nature Reserve (Colombia), probably Cayambe-Coca Ecological Reserve and Sangay National Park (Ecuador), and Manu National Park (Peru). The lower-elevation slopes where this species occurs, in many areas, face the greatest pressure from human colonization and deforestation, although there appears to be considerable intact habitat that is reasonably secure in at least the short term.

Bibliography. Chapman (1926), Davis (1972), Donegan & Dávalos (1999), Dunning (1982), Echeverry-Galvis & Córdoba-Córdoba (2007), Fjeldså & Krabbe (1990), Hilty (1997), Hilty & Brown (1986), Isler & Isler (1999), Lysinger *et al.* (2005), Moore *et al.* (1999), Parker & Parker (1982), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schulenberg *et al.* (2007), Walker (2001), Zimmer (1947b).

250. **Yellow-green Bush-tanager**



Chlorospingus flavovirens

French: Chlorospin jaune-vert **Spanish**: Clorospingo Verdiamarillo
German: Schwarzstirn-Buschtangare

Taxonomy. *Buarremon flavovirens* Lawrence, 1867, Pichincha, Ecuador.

Recent molecular-genetic studies indicate that this genus and *Nesospingus*, *Spindalis* and *Phaenicophilus* form a monophyletic clade that is sister to several New World warbler (Parulidae) genera (including *Dendroica*, *Basileuterus* and *Vermivora*), and are not closely related to other genera of present family. More recent evidence suggests that *Chlorospingus* is closest to genus *Arremonops* in family Emberizidae. Monotypic.

Distribution. SW Colombia (W slope of W Andes in upper Anchicayá Valley, in Valle del Cauca; Nariño) and Ecuador (in E Esmeraldas; Pichincha).

Descriptive notes. 14 cm; 22·5–27 g. Very plain, dingy bush-tanager, almost uniformly coloured throughout; strong-billed. Lores and ocular area are dusky (not in strong contrast to rest of head), otherwise head yellowish-olive (or olive-citrine); upperparts olive with faint yellowish tinge; bend of wing pale yellow (usually hidden), median and greater upperwing-coverts and primary coverts dull dark olive, flight-feathers dusky olive, edged dull yellow, tertials and tail dull dark olive; olive-yellow below, slightly paler and yellower, more olive-ochre, on centre of throat, centre of belly and undertail-coverts; iris brown to dark brown; upper mandible blackish with narrow base blue-grey, lower mandible blue-grey with dusky tip; legs dark grey. Sexes similar. Juvenile undescribed. Voice. Call a husky, often repeated "chup!" or "tsup!", coarser and more raspy than notes of other members of genus. Song unknown.

Habitat. Wet mossy forest and along forest borders and nearby tall trees in clearings. Recorded at 500–1050 m in Colombia.

Food and Feeding. Fruits, also small arthropods. Stomach contents of one birds included fig (*Ficus*) fruit and other vegetable matter. Of 91 foraging records in Colombia (Anchicayá Valley, in Valle del Cauca), 45% involved fruit, 34% were insect-searching, and 21% were at flowers (where ate either flower parts or possibly insects). More than 14 species of fruit were taken, mostly melastomes (75% of all fruit), especially *Miconia* berries. Travels in groups of 3–5 individuals, often with mixed-species flocks. Median foraging height c. 12 m, but regularly goes into canopy at 22–30 m, and into thickets or lower vegetation along forest borders, with many foraging-height records c. 7 m up. About 13% of observed fruit-eating events were at parasitic and epiphytic plants, and sometimes noted as flying directly from one mistletoe (Loranthaceae) clump to another. Took most fruit from perched positions, rarely hung from *Cecropia* catkins. Swallowed small fruits whole and mashed larger ones. Searched for insects mainly on all sides of large (more than 13 cm diameter) mossy branches and on tree trunks; also looked at patches of moss, hanging moss clumps, ferns and epiphytes. Perched upright, hung upside-down or clung to substrates to pick at prey. Rarely pursued escaping insects in air or sallied to moss or other surfaces. Once seen to tear apart a termite (Isoptera) nest.

Breeding. Two nests, one in Mar and one in May, in Colombia (Valle): a mossy cup 5 m and 7 m above ground, one in mossy tree fork, the other at base of palm fronds. No other information.

Movements. Resident. During an intensive 16-month observation period in 1972 and 1973 at a site in Anchicayá Valley (at 1050 m), ringed individuals were resident throughout.

Status and Conservation. VULNERABLE. Restricted-range species: present in Chocó EBA. Extremely local. At the few sites where it is known in SW Colombia and NW Ecuador it is rare or uncommon and difficult to find. In Colombia, found at one (possibly two) sites close to each other in Valle del Cauca and at four sites (all close together) in Nariño, and large areas of mostly intact habitat exist between these two areas. In Ecuador, recorded in Esmeraldas at El Placer, Awacachi Corridor, Alto Tambo, Cotacachi-Cayapas Ecological Reserve and Canandé Reserve, and in Pichincha occurs along the Milpe road. The species was relatively numerous along one E ridge of upper Anchicayá Valley, a region afforded protection over the years by privately operated companies because of a small hydropower site. Elsewhere within its tiny known range, pressure from human colonization and deforestation is likely to continue to place this species at serious risk. Logging, deforestation and land-use change are increasing almost throughout the species' range, with no indication of consideration for the environment, and even in reserves protection of the habitat is not efficiently enforced.

Bibliography. Álvarez-Rebolledo *et al.* (2007), Anon. (2010a), Butchart & Stattersfield (2004), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Fjeldså & Krabbe (1990), Griscom (1935), Hilty (1977, 1997), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1966, 1970a), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Stattersfield & Capper (2000).

251. **Ashy-throated Bush-tanager**

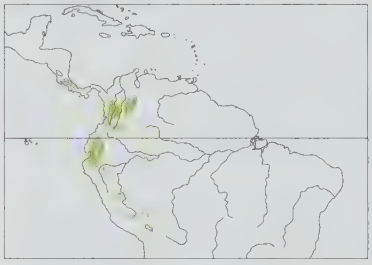
Chlorospingus canigularis

French: Chlorospin à gorge grise **Spanish**: Clorospingo Gorjigrís
German: Graukehl-Buschtangare

Taxonomy. *Tachyphonus canigularis* Lafresnaye, 1848, "Bogotá", Colombia.

Recent molecular-genetic studies indicate that this genus and *Nesospingus*, *Spindalis* and *Phaenicophilus* form a monophyletic clade that is sister to several New World warbler (Parulidae) genera (including *Dendroica*, *Basileuterus* and *Vermivora*), and are not closely related to other genera of present family. More recent evidence suggests that *Chlorospingus* is closest to genus *Arremonops* in family Emberizidae. It has been suggested that isolated race *olivaceiceps* may represent a separate species; this requires study. Five subspecies recognized.

Subspecies and Distribution.



C. c. olivaceiceps Underwood, 1898 – mountains in Costa Rica (mainly E slope in Central Valley and R Reventazón) and W Panama (Bocas del Toro).

C. c. canigularis (Lafresnaye, 1848) – S end of Venezuelan Andes (Táchira) and on W slope of E Andes in Colombia (S to vicinity of Bogotá).

C. c. conspicillatus Todd, 1922 – both slopes of W Andes (from Antioquia S to Cauca) and both slopes of C Andes (from Caldas S to Huila) of Colombia.

C. c. paulus J. T. Zimmer, 1947 – W slope of Andes from Ecuador (Chimborazo) S to NW Peru (Tumbes).

C. c. signatus Taczanowski & Berlepsch, 1885 – E slope from Ecuador (from Napo) S to Peru (Cajamarca, and spottily S to Cuzco).

Descriptive notes. 13–14 cm; 14·5–21 g. Grey-headed bush-tanager with bill more slender than that of congeners. Nominate race has crown and side of head grey, ear-coverts slightly darker; upperparts, including upperwing-coverts and tail, olive-green (back contrasting with grey head); throat clear greyish-white; broad chestband light yellow, this colour continuing down sides and flanks, where tinged olive; centre of breast and belly whitish to greyish-white, undertail-coverts olive-yellow; iris reddish-brown; bill sometimes all dusky, but often most of lower mandible pale steel-grey; legs dark grey. Sexes alike. Juvenile undescribed. Race *conspicillatus* is very similar to nominate, but yellowish breastband broader and slightly darker, and sides and flanks slightly more olive; *paulus* is very similar to previous and nominate, but has uniformly grey head (ear-coverts concolorous with crown) and is slightly smaller; *signatus* has head slightly darker grey, with narrow but conspicuous white postocular stripe continuing to nape; *olivaceiceps* differs from others in having head mainly olive, like upperparts. Voice. Song in Peru (race *signatus*) a high "seet" accelerated into rapid chittery trill, descending and then rising to abrupt end; call a high "chit". Song in Colombia a rather similar "tsuk...tsuk...chit-chit chi't't't't't'a'a'a'a'i'i'it'it-tit", trill rising slightly, then descending, and rising again at end. In Costa Rica, call a high, thin, sharp, penetrating "zeezít" or "dzee dzít", sometimes "zee zee zít"; possible song a sibilant, slightly ascending "tse tse tse tsee". In Venezuela gives thin chipping and rapid chittering notes when foraging.

Habitat. Canopy of tall, wet and mossy forest, vines in upper levels of forest, along edges and in mature second growth, occasionally in scattered trees in clearings by forest. Recorded at 300–1500 m in Central America; 1200–2600 m in W Venezuela and Colombia; in Ecuador, mostly 700–1300 m (locally down to 400 m) along W slope of Andes and mostly 1000–1900 m on E slope; 1000–1800 m in E Peru.

Food and Feeding. Diet not well known. Fruits recorded; in Costa Rica reported as eating berries from melastomes, Rubiaceae, *Hedyosmum*, etc. Forages in small active groups, occasionally up to ten individuals; joins mixed-species flocks and often with other bush-tanagers (especially *C. ophthalmicus*). Explores foliage, bare or mossy limbs, especially slender branches and ends of branches, and searches in vine tangles from near ground to treetops; unlike most other members of genus, more often high or in canopy, and seems particularly fond of vine tangles.

Breeding. Birds in breeding condition in Mar–May and Sept in Colombian Andes. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Uncommon to fairly common; perhaps somewhat local in Andes. Although it is not currently at risk, the middle-Andean elevations favoured by this species are often subject to intensive colonization pressure, which could eventually pose a threat at a local scale.

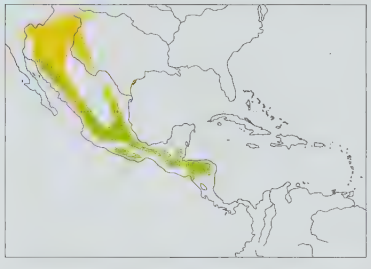
Genus *PIRANGA* Vieillot, 1807

252. Flame-colored Tanager

Piranga bidentata

French: Piranga à dos rayé **German**: Bluttangare **Spanish**: Piranga Estriada
Other common names: Striped/Swainson's Tanager

Taxonomy. *Pyranga bidentata* Swainson, 1827, Temascáltepec, Mexico.
Molecular-genetic evidence indicates that this genus forms a monophyletic group with *Habia* and *Chlorothraupis*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. Four subspecies recognized.
Subspecies and Distribution.
P. b. bidentata Swainson, 1827 – extreme SW USA (S Arizona, W Texas), and W Mexico from Sonora and Chihuahua S to Guerrero and E to vicinity of Mexico City.
P. b. flammea Ridgway, 1887 – W Mexico (Nayarit and Tres Marías Is).
P. b. sanguinolenta Lafresnaye, 1839 – E Mexico (from Nuevo León and Tamaulipas) S to Guatemala, NW Honduras and N El Salvador.
P. b. citrea van Rossem, 1934 – mountains of Costa Rica and W Panama.



Descriptive notes. 18–19 cm; 33·3–39·4 g (nominate), 32–48·4 g (*flammea*). Distinctive tanager with strong bill. Male nominate race has lores, ocular area and ear-coverts light brown, darker border to rear of ear-coverts; rest of head and entire underparts flame red-orange, becoming paler on lower underparts; mantle and back dusky orange, tinged olive, and boldly streaked black, rump paler and much less streaked (or with almost no streaking); tail dusky, tips of outermost feathers white (forming white tail corners); median and greater upperwing-coverts blackish, broadly tipped white (forming two conspicuous wingbars); primary coverts black, flight-feathers dusky, edged brown, tertials with large white spot on tip of each feather, and often a tiny white tip on several innermost secondaries; iris dark reddish-brown; bill blackish above, grey to dark grey below; legs blackish. Female is patterned like male, but head and underparts yellow, contrasting dusky ear-coverts, crown tinged olive; back olive, streaked black; upperwing and tail brownish, with markings as on male. Juvenile is like female, but pale yellow on head and underparts, and with variable amount of streaking below; immature male much like female, but head and underparts mottled with red or orange-red. Race *flammea* is similar to nominate, but paler red; *sanguinolenta* also is similar, but head and underparts bright red to orange-red, wingbars and tertial spots sometimes tinged red; *citrea* is somewhat paler and more orange below. Voice. Song, from high perch, a long series of phrases of 3–6 notes, rich, musical and reminiscent of a vireo (Vireonidae), but with slight burr, e.g. "chewee-very-vire, chewee-very-vire-very, cheery-chewee a..." and so on, which is much like that of *P. ludoviciana*. Call is a loud, hard "per-dick" or "chi-dick"; also gives a rapid, rolled "chit-t-t-t-tik" or "p-terruk" and a musical "chirrup".
Habitat. Canopy and treetops of moist and humid mountain forest, scattered trees in adjacent shady pastures, coffee plantations, gardens and other settled areas with large trees; in N part of range S to Nicaragua, also in open oak (*Quercus*) and pine–oak (*Pinus–Quercus*) woodland. From c. 800 m to tree-line in Mexico; locally down to near sea-level in Guatemala; in Costa Rica, c. 1850–2850 m on Caribbean slope and regularly down to 1200 m, rarely even to 900 m, on Pacific slope; mostly above 1200 m in Panama.
Food and Feeding. Small arthropods; also variety of berries, including those of Ericaceae, melastomes, *Ficus* and *Satyria*. Not very gregarious, usually seen alone or in pairs, only infrequently in small groups; may join mixed-species flocks, but also often seen independently of them. Forages in high branches of tall trees by peering. Captures arthropods by reaching out or lunging forward, also by frequently making short sallies to foliage or to air. Although usually high up, may occasionally descend low to fruiting shrubs, rarely even to the ground.
Breeding. Breeding reported in Apr and May in Costa Rica and May in Panama. Nest a loose open cup of stiff rootlets, slender twigs and vine tendrils, lined with fine grass stems and inflorescences, placed in dense foliage, often in cypress; four nests were in a variety of locations, mostly outside forest in trees and shrubs in pastures or in coffee plantations, three 1–7·5 m up, the fourth higher in top of medium-size tree; nests reported at 5–11 m in Costa Rica. Clutch 2–3 eggs, pale blue, speckled with reddish-brown and dark lavender, mostly at larger end. No other information.
Movements. Largely resident; in Mexico may move to lower elevations during winter months. Rare pre-breeding and post-breeding wanderer/vagrant in extreme S USA (Santa Rita, Huachuca, and Chiricahua Mts, in S Arizona; Big Bend National Park, in W Texas).
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Rare breeder in extreme S USA (S Arizona and W Texas), where first record (in Apr 1985, in Cave Creek Canyon, in Chiricahua Mts of Arizona) was of a male paired with a female *P. ludoviciana*. Occurs in a number of protected areas from Mexico S to W Panama, including, in Mexico, Cumbres de Majalca (Chihuahua) and Sierra de Manantlán National Parks (Jalisco) and La Michilía Biosphere Reserve (Durango), and also Celaque National Park (Honduras), Chirripó/La Amistad International Park (Costa Rica) and Volcán Barú and La Amistad National Parks (Panama). Range also encompasses large areas of unprotected highland woodland including pine–oak forest. Despite range contractions locally, the species is adapted to utilize disturbed and partially opened areas and park-like highland terrain, and is thus less sensitive to environmental disturbance than are many species.
Bibliography. Benesh (1997), Blake (1956), Binford (1989), Burns (1998a), Chapman (1898), Clark (1984), Davis (1972), Edwards (1972), Garrigues & Dean (2007), Hall (1965), Howell & Webb (1995), Isler & Isler (1999), Land (1970), Le Febvre & Warner (1959), Leck (1972b), Leck & Hilty (1968), Martin *et al.* (1954), McCarthy (2006), Morse & Monson (1985), Ogilvie-Grant (1912), Peterson & Chalif (1973), Ridgely & Gwynne (1989), Rosenberg & Witzman (1999), Sibley (2000, 2003), Skutch (1967a), Slud (1964), Stiles & Skutch (1989), Sutton & Pettingill (1942), Wetmore *et al.* (1984).

253. Northern Hepatic-tanager

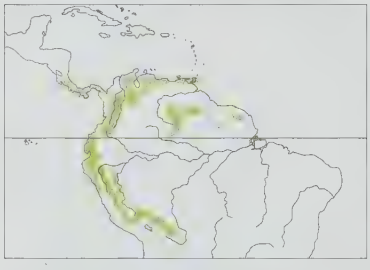
Piranga hepatica

French: Piranga à joues grises **German**: Nordzinnobertangare **Spanish**: Piranga Hepática
Other common names: Hepatic Tanager (when combined with *P. lutea* and *P. flava*)

Taxonomy. *Pyranga hepatica* Swainson, 1827, Temascáltepec, Mexico.
Molecular-genetic evidence indicates that this genus forms a monophyletic group with *Habia* and *Chlorothraupis*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. This species, *P. lutea* and *P. flava* have traditionally been treated as conspecific, but molecular-genetic analyses suggest that they are better regarded as three separate species, sequence divergence (cytochrome *b* gene) between individuals from extremes of range (Mexico and Bolivia) being as high as 6·1%; molecular-genetic data indicate that present species and *P. lutea* are sisters, with *P. flava* sister to them. Present species and *P. lutea* are the most similar in appearance, and *P. flava* and *P. lutea* differ most in areas where their distributions approach one another; analysis of geographical variation, however, complicated by considerable individual, age and seasonal variation. In the case of present species, wing and tail lengths vary somewhat, size decreasing from N to S (to Nicaragua), but bill length does not. Proposed races *zimmeri* (described from S Sonora, in NW Mexico) and *intensa* (from Oaxaca in S Mexico) are both treated as synonymous with nominate. Five subspecies provisionally recognized.
Subspecies and Distribution.
P. h. hepatica Swainson, 1827 – breeds SW USA (E California, Arizona and W New Mexico, casually elsewhere) S through highlands of Mexico (to Guerrero and Oaxaca); those in N migrate to S portion of breeding range or descend to lower elevations in winter.
P. h. dextra Bangs, 1907 – breeds S USA (mountains of New Mexico and W Texas) S through highlands of E Mexico (to C Veracruz, E Oaxaca and Chiapas); those in N migrate mainly to area from C Nuevo León and Tamaulipas S to W Guatemala or descend to lower elevations in winter.
P. h. figlina Salvin & Godman, 1883 – E Guatemala and Belize.
P. h. albifacies J. T. Zimmer, 1929 – highlands of W Guatemala, Honduras, N El Salvador and NC Nicaragua.
P. h. savannarum T. R. Howell, 1965 – extreme E Honduras and NE Nicaragua.

Descriptive notes. 18 cm; 23–47 g. Male nominate race has ear-coverts dusky grey (not in strong contrast); rest of head and upperparts dusky grey-brown, tinged red, brightest on forecrown and uppertail-coverts; lesser and median upperwing-coverts dusky with dull red fringes, greater coverts dusky, outer webs dull red (coverts appear mostly red); flight-feathers and tertials dusky, narrowly edged dull red, tail dull red, brighter on outer fringes; dull red below, brightest on throat; iris brown; strong bill with upper mandible mostly dusky, lower mandible blue-grey with dusky tip; legs grey. Female has ear-coverts dull grey, forehead to mid-crown yellowish, becoming duller towards nape, dullest on mantle and scapulars; lesser and median upperwing-coverts dusky with yellow-olive fringes, greater coverts vaguely edged yellow, flight-feathers dull dusky grey, primaries and most of secondaries edged dull yellow (not in strong contrast), tertials dusky, outer edge paler; tail dusky grey, tinged yellow; throat and undertail-coverts dull yellow to ochraceous yellow, middle of underparts dull grey with hint of yellow, sides and flanks olive. Subadult male acquires adult plumage at end of first year, but may show large patches of yellow in plumage. Races differ mainly in tone of plumage: *dextra* male is slightly smaller and darker than nominate, has both back and underparts slightly deeper red; *albifacies* male is overall much redder, with less contrasting grey on ear-coverts, female more uniformly yellow-olive above and more heavily washed olive below; *figlina* male is intermediate between nominate and previous; *savannarum* is most similar to last, but smaller, and adult male is brighter and with more orange tone, especially below, female brighter yellow ventrally, especially on throat and abdomen. Voice. Song a musical carolling "twee-hee chu-wíte cha-ha" etc., delivered slowly, with distinct pauses, and with a few hoarse notes. In SW USA sings from favourite high perch for half-hour or so at dawn, then moves around, singing from various trees, and eventually falls quiet. Calls include low, abrupt "chup" or "tchuk", less often a series of sharp rising notes, "chu-chit-it" or "chudidit"; flight call a husky, rising "weet".
Habitat. In all highland areas favours open oak or pine–oak (*Pinus–Quercus*) or pure pine woodland; outside breeding season may wander in parks, gardens and other areas with broadleaf trees. Lowland populations, e.g. in Belize (race *figlina*) and in E Honduras and NE Nicaragua (*savannarum*), occur primarily in pine savannas, but may irregularly wander or occur in adjacent broadleaf-woodland edge and coffee plantations. Elevations vary, mostly 1600–2300 m in SW USA, and to 3000 m in Mexico; 600–1800 m in Honduras, above 1100 m in El Salvador; also locally in lowlands.
Food and Feeding. Primarily insectivorous; also eats variety of vegetable matter, including domestic peppers, grapes, cherries and *Miconia* berries, and may take nectar from flowers including agaves, madrones and oaks. Contents of six stomachs were insects, including large ants (Formicidae). In territorial pairs when breeding, occasionally in small loose groups outside breeding period. Forages mostly in foliage, usually well up in trees, occasionally quite low; sometimes visits fruiting trees and shrubs. Forages by hopping rather slowly, peering at foliage and reaching out to peck prey; occasionally takes prey in air by making large looping aerial sallies within trees.
Breeding. Breeds May–Jul in USA and May and Jun in Mexico; Aug in Belize and Apr in Nicaragua. Male may assist female with nest-building; nest a loosely constructed cup of plant fibres and twigs, sometimes lined with pine needles, most often in oak or pine tree and placed 2–15 m up at end of branch. Clutch 3–5 eggs (usually 4), pale blue or greenish-blue with brown markings, these often concentrated in wreath at larger end; incubation by female alone. No other information.
Movements. Migratory in N portion of range in USA and N Mexico, moving S for unknown distance; in some other areas birds descent to lower elevations during winter months, or during rainy season.
Status and Conservation. Not assessed. Probably not globally threatened. Fairly common and relatively widespread. Found in numerous national forests, national parks and biosphere reserves from SW USA S to N Nicaragua. Its range also encompasses much intact foothill and higher-elevation pine–oak, evergreen and semi-evergreen forest, which, although not formally protected,

On following pages: 254. Highland Hepatic-tanager (*Piranga lutea*); 255. Lowland Hepatic-tanager (*Piranga flava*); 256. Summer Tanager (*Piranga rubra*); 257. Rose-throated Tanager (*Piranga roseogularis*).



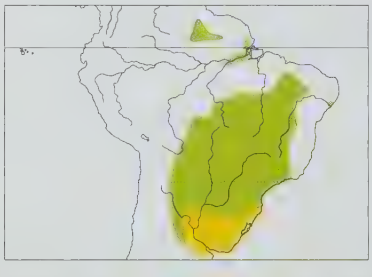
is not immediately threatened with deforestation or development. This species is also adapted to, or tolerates, a variety of disturbed and natural, semi-open wooded habitats.
Bibliography. Bent (1958), Binford (1989), Burns (1998a), Davis (1972), Dickey & van Rossem (1938), Eddleman (2002), Edwards (1972), Garrigues & Dean (2007), Howell, S.N.G. & Webb (1995), Howell, T.R. (1965, 1972), Isler & Isler (1999), Land (1970), Marshall (1957), Martin *et al.* (1954), Nehrkorn (1899), Poole (1938), Pough (1957), Rand & Traylor (1954), Remsen *et al.* (2010), Rowley (1962, 1966, 1984), Russell (1964), Schaldach (1973), Shy (1984b), Sibley (2000), Zimmer (1929).

254. **Highland Hepatic-tanager**

Piranga lutea

French: Piranga bourgogne **German**: Hochland-Zinnobertangare **Spanish**: Piranga Montana
Other common names: Tooth-billed Tanager; Blood-red Tanager (*haemalea*)

Taxonomy. *Pithylus luteus* Lesson, 1834, Callao, Peru.
Molecular-genetic evidence indicates that this genus forms a monophyletic group with *Habia* and *Chlorothraupis*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. This species, *P. hepatica* and *P. flava* have traditionally been treated as conspecific, but molecular-genetic analyses suggest that they are better regarded as three separate species, sequence divergence (cytochrome *b* gene) between individuals from extremes of range (Mexico and Bolivia) being as high as 6·1%; molecular-genetic data indicate that present species and *P. hepatica* are sisters, with *P. flava* sister to them. Present species and *P. hepatica* are the most similar in appearance, and *P. flava* and present species differ most in areas where their distributions approach one another; analysis of geographical variation, however, complicated by considerable individual, age and seasonal variation. Race *haemalea* of present species sometimes regarded as a separate species, and race *testacea* of lower Central American highlands also may prove to be vocally distinct from populations in Andes; more taxonomic work warranted. Six subspecies currently recognized.
Subspecies and Distribution.
P. l. testacea P. L. Sclater & Salvin, 1868 – highlands from N Costa Rica (Guanacaste) S to E Panama (E Darién).
P. l. desidiosa Bangs & Noble, 1918 – SW Colombia in middle and upper Cauca Valley (S from Antioquia, including isolated records at N end of both W & C Andean ranges) and W slope of W Andes (Dagua Valley S to upper Patía Valley, in Cauca).
P. l. lutea (Lesson, 1834) – Andes of SW Colombia (Nariño) S through W Ecuador and Peru (S to Lima in W, and on E Andean slope from S of Marañón Valley) S to WC Bolivia (Cochabamba).
P. l. faceta Bangs, 1898 – N Colombia (Santa Marta Mts) and Andes and N cordilleras of Venezuela (E to Paria Peninsula); Trinidad.
P. l. toddi Parkes, 1969 – E Andes of Colombia on W slope (at El Cauca, in Magdalena, and Serranía de los Yariguíes, in Santander) and E slope (Chicamocha National Park, in Norte de Santander).
P. l. haemalea Salvin & Godman, 1883 – tepuis of S Venezuela (in Amazonas and Bolívar), and adjacent N Brazil (Sierra Imeri) and the Guianas.



Descriptive notes. 17 cm; 28–40 g. Strong-billed tanager, overall slightly smaller and darker than *P. flava*. Male nominate race is bright red above, with dusky lores, faint pale streaking on ear-coverts and otherwise little contrast anywhere on upperparts; slightly paler below, more rosy on belly; iris brown; bill dusky horn above, paler horn-blue to faintly yellowish-horn below, especially at base; legs grey. Female is intense yellowish olive-green above, with with more golden or ochre tinge on forecrown; olive-yellow below, more olive on sides and flanks, throat and centre of belly usually more yellowish; more yellowish-olive above and on flanks than *P. flava*. Juvenile is dull, female-like in plumage, and with brownish streaking above and below; subadult male like female, but irregular patches of red appear, especially on foreparts, and brighter yellow below. Race *testacea* similar to nominate but more orange-red below; *desidiosa* is darker than nominate, male deeper red, ear-coverts not streaked, female with more strongly olive-tinged back; *haemalea* is notably darker, male maroon-red above, deep carmine-red below, with brighter throat and lower underparts, female also darker above than previous; *faceta* male is light brick-red to orange-red, with dusky grey lores, female paler, close to female of nominate; *toddi* male is much like male of last, but lores blackish, red upperparts faintly grey-tinged, less scarlet, flanks washed grey, and belly close to begonia-rose, female deepest yellow below, almost orange-yellow on throat, with very dark flanks. Voice. Song in Costa Rica a musical carolling of 5–7 rising and falling notes, higher in pitch than song of *P. bidentata* and with slight burry quality, "chew-chewee-cheer-cheeur-chuee"; in coastal cordillera of Venezuela a musical and leisurely, if somewhat choppy, series of throaty phrases, rising and falling, e.g. "wueep, purty, churdik, wudik, purty, wordik, chueet, breep, cheet", or shorter "whip, chew'wip, worry, jury, keép-fit". Song length varies, typically c. 4–8 phrases, and is rather repetitious. Dawn song similar but longer, and with only slight pauses between songs. Songs in S Peru (Cuzco) similar. Call in Costa Rica a quick series of 3–4 sharp rising notes, "chu-chit-it" or "chudidit"; commonest call in Venezuela and elsewhere in Andes a simple "chup", used also in alarm.
Habitat. Typically in rather open woodland, second growth and adjacent tall trees in clearings, coffee plantations, along forest borders, even parks, gardens and occasionally urban areas; occurs, at least sporadically, in dry scrub in foothills of coastal cordillera in Venezuela. In Costa Rica reported as occurring also in canopy of humid mountain forest. Found from c. 900 m to 1850 m, locally down to 600 m, in Costa Rica; in Venezuela, 450–2050 m N of Orinoco, and in S (race *haemalea*) 800–1800 m; mostly 1500–2200 m but locally down to 200 m in Colombia; lowlands to 1900 m on W slope and 1000–1350 m on E slope of Andes in Ecuador; 400–2700 m in Peru (both slopes).
Food and Feeding. Insects, including large beetles (Coleoptera) and caterpillars, and in Trinidad butterflies (Lepidoptera); also buds, berries and fruits, seeds and nectar. Of eight stomachs examined, one contained only vegetable matter and five only animal matter, and two held both; contents included beetles, caterpillars, a bee (Apoidea), an orthopteran, and seeds. Forages singly and in pairs, often slightly away from forest, and only infrequently with mixed-species flocks. Forages at a variety of heights, mostly high in trees, or in tops of low trees in scrubby areas. Hops sluggishly and peers in canopy and middle-level foliage; sallies to air in large looping circles within trees, or executes short rather awkward sallies, or flutters to foliage or to branch or trunk surfaces for variety of often large insect prey. Seen to probe flowers.
Breeding. Breeding reported in Feb, Jul and Oct in Trinidad; in Colombia, birds in breeding condition in Jun–Nov in Santa Marta Mts, in C Andes (in Cauca) and above Cali (in W Valle); nest found in early Mar in SW Ecuador (Tambo Negro, in Loja). In Trinidad, cup-nest of dry grass 6 m up in young vegetation at clearing edge; in Colombia (Santa Marta Mts) a frail flat structure of fine rootlets, two in roots under overhanging bank along road, a third 0·6 m up in small shrub on top of road bank. In Trinidad, clutch 2 eggs, blue or greenish, spotted with grey, violet or brown; chicks fed by both adults. No other information.
Movements. Mostly resident. May wander when not breeding, and some altitudinal migration to lower elevations possible during rainiest months.
Status and Conservation. Not assessed. Probably not globally threatened. Uncommon to locally fairly common. Found in numerous parks, biosphere reserves and refuges across its extensive, mostly Andean range. Occurs also in many areas of unprotected but relatively intact montane habitat. This species also utilizes a variety of lightly wooded and relatively open, second-growth and disturbed habitats, and fairly dry to humid regions, which to some extent protects it against habitat-related risks. Said to be a pest locally in corn fields.
Bibliography. 255. **Lowland Hepatic-tanager**

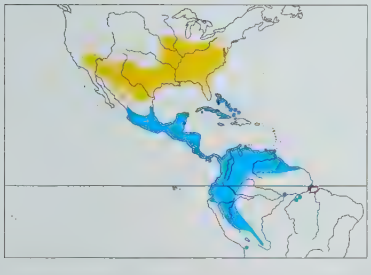
Piranga flava

French: Piranga orangé **German**: Südzinnobertangare **Spanish**: Piranga Bermeja
Other common names: Red Tanager

Taxonomy. *S.*[*altator*] *Flavus* Vieillot, 1822, Paraguay.
Molecular-genetic evidence indicates that this genus forms a monophyletic group with *Habia* and *Chlorothraupis*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. This species, *P. hepatica* and *P. lutea* have traditionally been treated as conspecific, but molecular-genetic analyses suggest that they are better regarded as three separate species, sequence divergence (cytochrome *b* gene) between individuals from extremes of range (Mexico and Bolivia) being as high as 6·1%; molecular-genetic data indicate that *P. hepatica* and *P. lutea* are sisters, with present species sister to them. Present species and *P. lutea* differ most in areas where their distributions approach one another; analysis of geographical variation, however, complicated by considerable individual, age and seasonal variation. Race *macconnelli* very poorly differentiated from *saira* and may be better subsumed within it; thorough review required. Four subspecies provisionally recognized.
Subspecies and Distribution.
P. f. macconnelli C. Chubb, 1921 – S Guyana and N Brazil (E Roraima) E to S Suriname; possibly also French Guiana.
P. f. saira (Spix, 1825) – E & S Brazil (both banks of R Amazon in Amapá and C Pará; SE Alagoas; and from C Maranhão and C Piauí S to E & S Mato Grosso and Rio Grande do Sul).
P. f. rosacea Todd, 1922 – E Bolivia (E Santa Cruz).
P. f. flava (Vieillot, 1822) – SE Bolivia (from Cochabamba and S Santa Cruz), Paraguay to N & C Argentina (S to Mendoza, Córdoba, N Buenos Aires) and Uruguay.

Descriptive notes. 18 cm; 30–40 g. Strong-billed tanager, overall lighter in colour than *P. lutea*. Male nominate race is mostly red to orange-red, somewhat tinged brownish above, including tail; forecrown, throat and breast brighter, lighter and more contrasting, with decidedly pinkish to peach-red colour; lores dusky; iris dark brown; bill blackish above, paler horn-blue to yellowish-horn below with dusky tip; legs dark grey. Female is yellowish-olive above, strongly tinged sandy-olive, dusky line on lores, weak yellowish eyering, forecrown and underparts fairly bright yellow, sides and flanks pale sandy-buff; weakly indicated yellowish eyering. Juvenile is like female, but somewhat streaked with dull brown above and below; subadult male like female, but with irregular patches of red showing in plumage, especially foreparts. Race *rosacea* male differs from nominate in having less grey edging on upperparts, and underparts more orange-scarlet (not pinkish), although underpart colour quite variable (from salmon-orange to flame-scarlet), female very like female of *saira* but slightly more greyish above; *saira* male is very like nominate, but slightly deeper and richer red above and uniformly bright scarlet-pink below, female darkest olive-grey above; *macconnelli* is exceedingly similar to last, differing perhaps in lighter average coloration of upperparts of male, female differs from nominate female in brighter citrine-olive upperparts, orangy supraloral area, dirty yellowish-white lores, and variable orange tinge on anterior underparts. Voice. Song, in Argentina, described as a repeated "tschip-tschurr", melodious but with little variation; in Brazil a melodious but little-varied stanza, "jip-jewlo, jewlo-jip", and in SE Brazil gives a loud "chip, chap, cherít". Call transcribed variously as a soft "chef" or "chu chu" and a loud "tchip" or "tcherit".
Habitat. Deciduous and gallery forest, borders of *Araucaria* forest, eucalypt (*Eucalyptus*) groves, *cerrado* and other open to semi-open areas with scattered trees. Found mainly in savanna with scattered trees in N portions of range, and in open deciduous woodland in S. Lowlands and foothills throughout most of range; c. 500–1200 m (probably somewhat lower, at least occasionally) in Suriname, and to 2050 m in SE Brazil.
Food and Feeding. Variety of arthropod prey, including caterpillars and spiders (Araneae); also variety of berries and fruit, especially figs (*Ficus*). Of four stomachs examined, one contained only animal matter and three contained both plant and animal matter; contents included termites (Isoptera), beetles (Coleoptera), hymenopterans, hemipterans, feathers, and fruit pulp. Occurs in pairs when breeding; in S of range, many may gather in groups on migration. Like others of genus forages mostly high or in upper branches of trees, sometimes also lower, rarely down to ground. Takes prey from foliage and bark and twig surfaces, and sallies for flying insects, mostly in or close to trees.
Breeding. Breeding reported in Nov SE Brazil (Rio Grande do Sul) and Oct in Paraguay; two males in breeding condition in Aug and Oct in mountains of Suriname. Nest a loosely woven, flat, cup-shaped structure of dry leaves, roots, grass stems and similar, usually placed on high branch,



some nests reported as low as 2 m up in bush. Clutch 3–4 eggs, greenish-blue or white, marked reddish-brown or cinnamon. No other information.
Movements. Resident in most of range. S populations (SE Brazil, Uruguay and Argentina) migratory; in Córdoba (W Argentina) moves downslope into valleys during coldest months.
Status and Conservation. Not assessed. Probably not globally threatened. Common to locally common, and widespread. Found in numerous parks and reserves, especially in Brazil. Occurs also in areas that are not formally protected, but do have extensive intact habitat. This species also utilizes a variety of lightly wooded and relatively open, second-growth and disturbed habitats in both dry and humid regions, providing a buffer against habitat-related risks. May be expanding its range following habitat disturbance and the opening-up of forested areas. No significant risks in the near term.

256. Summer Tanager

Piranga rubra

French: Piranga vermillon **German**: Sommertangare **Spanish**: Piranga Roja

Taxonomy. *Fringilla rubra* Linnaeus, 1758, South Carolina, USA.
Molecular-genetic evidence indicates that this genus forms a monophyletic group with *Habia* and *Chlorothraupis*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. Proposed race *ochracea* (described from Trout Creek, near Cane Springs, in W Arizona) is considered synonymous with *cooperi*. Two subspecies recognized.
Subspecies and Distribution.
P. r. cooperi Ridgway, 1869 – breeds SW USA (from SE California, S Nevada and C Arizona E to W Texas) and N Mexico (S to to NE Baja California, Sonora, N Durango, SW Coahuila and C Nuevo León); winters C & S Mexico (from S Sinaloa S to Michoacán, Morelos and Guerrero).
P. r. rubra (Linnaeus, 1758) – breeds E USA (from SE Nebraska, S Iowa, Ohio and Delaware S to C Texas, Gulf Coast and Florida); winters from S Mexico (Michoacán, Pueblo, Veracruz and Yucatán) S to N South America (S occasionally to N Bolivia, W Brazil and SE Venezuela, occasionally the Guianas.

Descriptive notes. 17–18 cm; 23·9–38·1 g (heaviest prior to migration), in boreal winter 21·6–32 g. Distinctive, with pale-looking bill, and occasionally appearing slightly crested. Male nominate race is red above, with head (including lores), throat and underparts bright rose-red to geranium-red; flight-feathers dusky, edged red; tail feathers red, duskier on inner webs; iris dark brown; bill pale to dusky horn, usually with faint yellowish tinge (typically looks obviously pale); legs dark grey. Female is brownish-yellow with olive tinge, underparts yellow to buff to cinnamon, sometimes with tinges of orange above and below. Subadult male is brownish-yellowish, like female, but by end of first year may show patches of red in irregular pattern, especially on head and foreparts; immature female often has dull orangish wash on belly. Race *cooperi* male is similar to nominate, but larger (on average 15% longer-billed and longer-tailed) and slightly paler, female is pale olive to pale olive-grey above, becoming pale yellowish-olive on lower back and rump, and light yellow on underparts, sometimes dusky loral area and greenish undertail-coverts (occasionally shows orange tinge, but in general paler than nominate). Voice. Song a slow musical carolling of mostly 3-syllable notes, some slightly burry, and with brief but distinct pause between phrases; songs of E birds (nominate race) lower in pitch than those of W populations (*cooperi*). On wintering grounds frequently gives calls but not songs. Call, in all areas, a loud, staccato "pik-tup", or "pik-a-tup" or extended to "pik-a-tuptup".
Habitat. In E portion of breeding range occurs in open hardwood forest; W populations found mainly in riparian woodlands that contain cottonwoods (*Populus*), willows (*Salix*), mesquite (*Prosopis*) and occasionally oak (*Quercus*) woodland, as well as shady parks and patches of trees. Generally overwinters in humid regions, but not inside humid forest; occupies open woodland, tall open second growth, forest borders, shady plantations and parks and gardens, even trees in cities, and occasionally scrub habitats. On non-breeding grounds in South America occurs from lowlands to at least 2700 m, most frequently above c. 500 m.
Food and Feeding. Mostly arthropods, including many bees and wasps and wasp larvae (Hymenoptera), also some fruits. In Arizona study, prey items predominantly flying insects less than 30 mm in length. Of 19 stomachs examined, one contained only vegetable matter, 17 held only animal matter and one contained both; contents mostly wasps. Other reported items include cicadas (Cicadidae), grasshoppers (Caelifera), beetles (Coleoptera, including weevils), ants (Formicidae), spiders (Araneae), caterpillars, dragonflies (Anisoptera) and other arthropods, as well as small fruits, including blackberries (*Rubus*) and whortleberries (*Vaccinium*). On wintering grounds also takes more insect prey than fruit; fruit items include *Miconia*, *Ficus*, *Cecropia*, mistletoe berries (Loranathaceae) and arillate fruits; stomach contents of seven birds contained only animal matter, including hymenopterans and dipterans. Occurs in pairs when breeding, otherwise usually alone. In E of breeding range typically forages in upper foliage of tall trees, where can be difficult to see. Reaches and pecks prey from twigs, foliage, bark, even flowers, and sallies short distances to air for flying insects, mostly within trees. In willow-dominated riparian woodlands in Arizona, breeding birds foraged at all heights from near ground to tops of trees, but rarely went to the ground. Most foraging occurs in outer part of branches, where branch diameter usually less than 7·5 cm. On wintering grounds usually solitary, apparently maintaining individual territories; may join mixed-species flocks, and often with temporary mixed feeding associations in fruiting trees. Foraging behaviour on wintering grounds similar to that when breeding, including frequent rapid swooping sallies to air, and picks fruit while perched or takes it in sallies; has been seen attending army-ant swarms.
Breeding. Season May–Aug in USA. Nest built by female alone, accompanied by male, a shallow cup of dry herbaceous vegetation, lined with fine grass, and placed on horizontal branch 2·5–15 m up in tree. Clutch 3–4 eggs, rarely 5, pale blue or greenish-blue, heavily spotted reddish-brown and faintly marked lilac-grey, sometimes forming a wreath or cap at large end; incubation by female, period 11–12 days; chicks fed by both adults, no information on duration of nestling period.
Movements. Entire breeding population migratory, wintering mainly from C & S Mexico S to W Ecuador, N Bolivia, C Amazonian Brazil and Suriname, once in NW Chile. Uncommon passage migrant and rare winter resident across most of West Indies. Present in Colombia mainly Oct–Apr.
Status and Conservation. Not globally threatened. Widespread and fairly common to common breeder across USA and N Mexico. Found in numerous protected areas. Utilizes a variety of habitats, including forest edges, second growth, partly cleared areas and park-like areas, an adaptability which buffers this species against potential threats. On wintering grounds loss of forested or partly forested habitat, including conversion of shade coffee plantations to sun coffee, is a threat, but overall impact of this remains unknown. Populations wintering in Central America face significantly more degradation and loss of forest and wooded habitat than do those wintering in N South America. In its breeding areas, the species is vulnerable to forest fragmentation which permits intrusion of cowbirds (*Molothrus*) and subsequent increases in nest parasitism.

257. Rose-throated Tanager

Piranga roseogularis

French: Piranga à gorge rose **German**: Rosenkehltangare **Spanish**: Piranga Yucateca

Taxonomy. *Pyranga roseo-gularis* S. Cabot, 1846, Yalahau, Quintana Roo, Mexico.
Molecular-genetic evidence indicates that this genus forms a monophyletic group with *Habia* and *Chlorothraupis*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. Three subspecies recognized.
Subspecies and Distribution.
P. r. roseogularis S. Cabot, 1846 – drier N portions of Yucatán Peninsula (N Campeche, N Yucatán and N Quintana Roo), in SE Mexico.
P. r. cozumelae Ridgway, 1901 – islands of Mujeres and Cozumel, off NE Quintana Roo.
P. r. tincta Paynter, 1950 – more humid C & S portions of Yucatán Peninsula, N Guatemala and Belize.

Descriptive notes. 16 cm; 21–30 g. Heavy-billed, comparatively dull tanager. Male nominate race has entire crown deep rose, lores dusky, large white eyering; rest of side of head, neck and upperparts grey with brownish tinge, uppertail-coverts reddish; tail dull crimson; upperwing-coverts dusky, broadly edged crimson, flight-feathers dusky, narrowly edged crimson, tertials mostly crimson; throat to upper breast bright rose, rest of underparts grey to buffy grey, tinged rose-pink on undertail-coverts, sometimes also a slight pink tinge on lower breast to central belly; iris dark brown; bill greyish, darker culmen; legs dark grey. Female has crown bright olive-yellow, side of head and upperparts duller yellowish-olive, upperwing and tail slightly darker yellowish-olive; conspicuous white eyering; throat and central foreneck yellow, turning pale grey on breast and whitish on lower underparts; undertail-coverts tinged yellow. Juvenile undescribed; immature male like female, but acquires dull reddish edges of greater wing-coverts in first pre-breeding moult; immature female duller than adult, throat pale lemon. Race *tincta* male is overall paler than nominate; *cozumelae* is somewhat darker than mainland birds. Voice. Song a rich warbled "whee chee cheer-el-chee cheer-el-cheu chee-el-chu..." and so on. Call a raspy, slightly nasal "rreh", and a nasal mewing "myaaa" suggesting a Grey Catbird (*Dumetella carolinensis*).
Habitat. Mainly semi-humid to humid forest edge and scrubby forest with thick undergrowth, infrequently inside tall forest; also occasionally in more open situations with scattered trees and low scrubby vegetation. Sea-level to c. 250 m.
Food and Feeding. Little information. In pairs when breeding. Forages in middle or upper part of medium-sized trees, and often in canopy with mixed-species flocks. Also observed to forage in undergrowth and in saplings, and has been reported as visiting fruiting trees and army-ant (Formicidae) swarms.
Breeding. No information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to locally common in scrub woodland on Yucatán Peninsula. Race *cozumelae* uncommon on Cozumel I, where appears to have declined since 1980s. Range encompasses several parks and biosphere reserves, including Sian Ka'an and Calakmul Biosphere Reserves, as well as Punta Put and Teacuterminos Lagoon Reserves. There is also extensive unprotected intact habitat within the species' range, and it tolerates some disturbance and scrubby second growth, which provides an additional buffer against near-term threats. Although portions of the area within its range are subject to considerable human-caused environmental pressures, the species does not appear to be at any immediate risk.

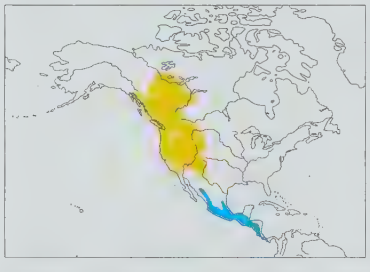
258. Scarlet Tanager

Piranga olivacea

French: Piranga écarlate **German**: Scharlachtangare **Spanish**: Piranga Escarlata

Taxonomy. *Tanagra olivacea* J. F. Gmelin, 1789, New York, USA.
Molecular-genetic evidence indicates that this genus forms a monophyletic group with *Habia* and *Chlorothraupis*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. This species has in the past been regarded as most closely related to *P. ludoviciana*, in part because of limited hybridization with that species, but cladistic analysis based on mitochondrial DNA (cytochrome *b* gene) indicates that the two are not each other's closest relative. *P. ludoviciana* appears to be most closely related to *P. bidentata* and the "*P. flava* group", the three forming a phylogenetic clade; depending on analyses used, the present species would be either a sister taxon to this clade, or sister to this clade and *P. rubra*. Monotypic.
Distribution. Breeds SE Canada (SE Manitoba E to S Quebec) S in E USA to N Arkansas, N Alabama, W North Carolina and Virginia and W to C South Dakota and C Kansas. Migrates to NW South America, mainly in W Amazon Basin from SE Colombia, E Ecuador and N Peru E to W Brazil and S to C Bolivia.



Descriptive notes. 17 cm; 23·5–33 g, prior to migration 32–38 g. Male breeding is bright red, with contrasting jet-black scapulars, upperwing-coverts, flight-feathers, tertials and tail; iris dark brown; bill entirely horn-grey to dull yellowish-horn; legs dusky grey. Non-breeding male is dark olive above, olive-yellow below, brighter on throat and lower underparts, but with scapulars, wing-coverts, flight-feathers, tertials and tail black. Female is plain dark greyish-olive above, paler and more olive-yellow below, palest on throat, and slightly brighter, more yellow, on chest, centre of breast and undertail-coverts; median and greater upperwing-coverts dusky, broadly edged yellow-olive, flight-feathers dusky, narrowly edged yellowish-olive. Subadult male much like female, but usually with some black on shoulder and/or pale yellow edgings on greater coverts and tertials; first-year male in breeding plumage may be dull red to orangish. Voice. Song of male, from very high perches when establishing territory (somewhat lower once nesting underway), a series of musical carolling phrases; easily confused with songs of American Robin (*Turdus migratorius*) and *P. rubra*, but phrases slurred and with distinctly hoarse quality (like American Robin with sore throat). Female also sings when gathering nest material and food, but songs shorter and softer than male's. Commonest call a rough "chik-burrr", with some regional variation; others include a thin "sweeee" in courtship, a nasal whistle when arriving at nest, and high descending screech in distress. Flight call a clear whistled "puwi".
Habitat. Breeds in humid E deciduous hardwood forests and mixed pine–oak (*Pinus–Quercus*) woodland, also parks, orchards and large shade trees in urban areas. On migration occurs in both forest and more open habitats, including woodlots, parks and urban areas with trees. Winters mostly in more heavily forested areas in South America than does *P. rubra*. To at least 1800 m on breeding grounds in USA; on migration up to 3000 m in Colombia; c. 2500 m in Ecuador, and to 1500 m in Peru.
Food and Feeding. Mostly insectivorous during breeding. Principal food hymenopterans, lepidopterans (especially caterpillars and moths) and both adult and larval beetles (Coleoptera); other animal foods recorded include spiders (Araneae), dragonflies (Anisoptera), orthopterans, and flies (Diptera); in early spring (in absence of foliage or during extended wet weather) may forage on ground for grasshoppers (Caelifera), ground beetles (Carabidae), earthworms (Oligochaeta), and other terrestrial invertebrates. Also takes some cultivated fruits such as cherries, and wild fruits and buds. Nestling diet insects and fruit. On migration in W Colombia seen to take insects from *Cecropia* and to eat *Cecropia* catkins. In pairs when breeding. Solitary on wintering grounds, but regularly joins mixed-species flocks in canopy, and feeding aggregations at fruiting trees. In small loose groups when migrating, seldom more than 10–20, rarely groups up to 50 reported in Colombia, where may remain for short periods in vicinity of a fruiting tree. On both breeding and wintering grounds spends most of time high in foliage of tall trees, often not moving much, hence can be difficult to locate. Most foraging done at middle heights, e.g. c. 6–18 m up; in New Hampshire mean foraging height was 12·8 m (in 22-m canopy). Searches for arthropods mostly by peering around and hopping in deliberate, almost slow manner, to examine foliage, twigs and branches. Regularly picks prey from outer leaf clusters, and will sally within trees for flying insects such as hymenopterans; may fly off fairly long distance to another tree.
Breeding. Season May–Jul; single brood. Males arrive before females on breeding grounds and establish territories. Territory boundaries somewhat flexible, and males frequently dispute boundaries when females present. In courtship, male descends to perch only 1–2 m above ground, and droops wings and stretches neck to expose scarlet back to female perched above. Female selects nest-site and builds nest alone; nest a shallow cup of plant stems, rootlets, grass, occasionally twigs, lined with finer material (eggs often visible through thin walls of nest), located on horizontal branch mostly 6–18 m up, infrequently much higher or lower. Clutch 2–5 eggs, mostly 3–4, dull white to greenish-blue, with brown markings concentrated at large end; incubation by female, often fed by male, period 12–14 days; chicks fed by both adults, nestling period 9–15 days.
Movements. Migratory; entire population makes post-breeding movement through Central America and a few through Caribbean region to N Amazonia. On wintering grounds recorded as far E as French Guiana. Uncommon to fairly common transient in Mexico, mostly S from S Veracruz and Yucatán. An uncommon passage migrant (so far as is known) through Andes of Colombia; a small number reported on Sabana de Bogotá during Nov–Mar. Considered a rare migrant across most of Caribbean, mainly Sept–Oct and even less frequent in Mar–May; very rare in Hispaniola, Puerto Rico, Virgin Is and N Lesser Antilles, and only a vagrant in S Lesser Antilles. Vagrant records throughout W USA, and rarely N to Alberta, in Canada.
Status and Conservation. Not globally threatened. Widespread and fairly common to common in breeding area, where found in numerous national forests and other national protected areas. Utilizes variety of habitats, including forest edges, second growth, and partly cleared and park-like areas, which offers some safeguard against potential threats. Not seen on South American wintering grounds in proportional numbers, and even in presumed main wintering area (in N Amazonia) this species is under-reported and seemingly scarce. On breeding grounds vulnerable to forest fragmentation, which permits intrusion by cowbirds (*Molothrus*) and subsequent increase in nest parasitism. Breeding censuses and other data suggest that the population is in decline.
Bibliography. Anon. (2000), Baldwin & Kendeigh (1938), Bent (1958), Brush (1967), Burns (1997a, 1998a), Burns *et al.* (2002, 2003), Connell *et al.* (1960), Cruz (1974), Davis (1972), Dechelle & Ingels (2007), Garrigues & Dean (2007), Graber & Graber (1962), Groskin (1943, 1950), Hales (1896), Harrison (1975), Hilty (1994, 1997, 2003), Hilty & Brown (1986), Howell & Webb (1995), Isler & Isler (1999), Klatt *et al.* (2008), Klicka *et al.* (2007), Land (1970), Landestoy *et al.* (2006), McCarthy (2006), Mee *et al.* (2002), Meyer de Schauensee (1966, 1970a), Mowbray (1999), Ogilvie-Grant (1912), Patterson & Allen (1968), Pearson (1972), Pough (1946), Prescott (1964, 1965), Raffaele *et al.* (1998), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Roberts & Norment (1999), Sabo & Holmes (1983), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Shy (1983, 1984a, 1984b, 1984c), Sibley (2000), Sick (1985, 1993), Skutch (1980b), Souza (2002), Stewart & Skinner (1967), Stiles & Skutch (1989), Terborgh (1989), Vega Rivera *et al.* (2003), Walley (1989), Weidensaul (1999), Yuri & Mindell (2002), Zimmer (1945).

259. Western Tanager

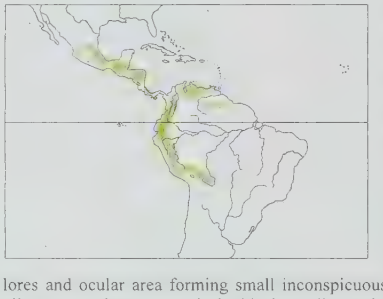
Piranga ludoviciana

French: Piranga à tête rouge **German**: Kieferntangare **Spanish**: Piranga Carirroja

Taxonomy. *Tanagra ludoviciana* A. Wilson, 1811, near Kamiah, Idaho, USA.
Molecular-genetic evidence indicates that this genus forms a monophyletic group with *Habia* and *Chlorothraupis*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. This species has in the past been regarded as most closely related to *P. olivacea*, in part because of limited hybridization with that species, but cladistic analysis based on mitochondrial DNA (cytochrome *b* gene) indicates that the two are not each other's closest relative. Present species appears to be most closely related to *P. bidentata* and the "*P. flava* group", the three forming a phylogenetic clade; further, vocalizations and several plumage characteristics support close relationship with *P. bidentata*, and the two are known to hybridize. Birds from Texas, described as race *zephyrica*, considered to fall within the range of variation of the population as a whole. Monotypic.
Distribution. Breeds S Alaska, and W Canada (from British Columbia and S Mackenzie, N Alberta and S Saskatchewan) S in W USA (E to Wyoming and C Colorado) to SW California, S Arizona, New Mexico and W Texas, and extreme NW Mexico (N Baja California). Migrates to mountains of W Mexico (from Jalisco and S Tamaulipas) S locally to Costa Rica and, rarely, W Panama.

Descriptive notes. 17 cm; 22·5–36 g, in boreal winter 28–34·5 g. Male breeding has forehead and crown, lores, ocular area, malar area and throat rose-red to bright red fading to bright yellow of neck and breast; mantle and scapulars black, lower back to uppertail-coverts bright yellow; wings black except for bright yellow median coverts, broad pale yellow to white on tips of outer webs of greater coverts, and narrow pale edges to outer webs of secondaries and especially tertials; tail black; most of underparts bright yellow; iris dark brown; bill horn-grey with yellowish tinge, cutting edges paler and more yellowish; legs grey. Non-breeding male is similar but duller, red colour on head faint, variable and confined to face, back somewhat mottled black. Female occurs in two colour morphs: yellow morph similar to male, but no red on head, yellow much duller, back and wings grey, wingbars weaker, and bill tends to be more yellowish-orange and less dusky; grey morph generally greyer, duller and more uniform, with bill more yellowish. Juvenile is similar to female. Voice. Song a series of throaty carolling phrases, much like that of *P. olivacea*. Commonest call a loud "pit-ick" or varied to "pit-er-ick"; also a burry "tu-weep". Flight call a soft whistled "howee" or "weet".
Habitat. Open coniferous forest, also mixed coniferous and deciduous forest and mature aspen (*Populus*) and alder (*Alnus*) groves. On wintering grounds found in pine and pine–oak (*Pinus–Quercus*) woodlands, scrubby forest and shady coffee plantations. During migration occurs also in variety of more open habitats, including desert scrub, parks and gardens. In El Salvador, reported as arriving in highlands, then spreading out into lowlands, but returning to highlands above c. 600 m before N migration. Breeds mainly at 1000–3050 m; as low as 450 m in Washington, and mostly above 2300 m in SW USA.
Food and Feeding. Mostly insects. Contents of 47 stomachs (Apr–Aug) were 82% insects and 18% fruit: hymenopterans, mostly wasps but some ants (Formicidae), accounted for 56% of the insect food, increasing to 75% in Aug; a further 12% were beetles (Coleoptera), including click beetles (Elateridae) and wood-borers; bugs (Hemiptera), including stink-bugs (Pentatomoidea) and a few cicadas (Cicadidae), made up 8%, grasshoppers (Caelifera) 4%, and caterpillars 2%; fruit included some large unidentified items, also elderberry (*Sambucus*) seeds, also raspberry or blackberry (*Rubus*) seeds. Other stomachs contained hemipterans and fruit and plant matter. Noted also as eating berries of juniper (*Juniperus*) and cotoneaster (*Cotoneaster*) and wild cherries (*Prunus*). Nestling diet adult and larval insects. On wintering grounds in El Salvador, consumed fruit and foraged in middle or upper branches of trees. In pairs when breeding, but solitary on wintering grounds. On migration may gather in mostly small loose groups, but flocks of up to 30 individuals reported; occasionally more, once reported in "large" numbers at a fruiting tree with Clay-coloured Thrush (*Turdus grayi*). Forages mostly in canopy or upper levels of coniferous and mature alder trees, mostly for insects. Sallies varying distances to air for flying ants and termites (Isoptera); sometimes remains motionless except for head movements as it watches for flying prey. Examines foliage in slow, methodical manner, hopping or jumping from perch to perch, and taking prey mostly by reaching or pecking from foliage, also from flowers.
Breeding. Season May–Jul. Cup-nest built from twigs, rootlets, grass and pine needles, lined with hair and fine rootlets, and placed 1·8–20 m up on outer horizontal limb, usually of fir (*Abies*) or pine, nest tree often in open area; one nest reported under ledge on ground. Clutch 3–5 eggs, pale blue or greenish-blue with brown or grey-green markings, these concentrated at larger end; incubation by female alone, period c. 13 days; chicks fed by both adults, no information on duration of nestling period.

On following pages: 260. White-winged Tanager (*Piranga leucoptera*); 261. Red-headed Tanager (*Piranga erythrocephala*); 262. Red-hooded Tanager (*Piranga rubriceps*); 263. Western Spindalis (*Spindalis zena*); 264. Jamaican Spindalis (*Spindalis nigricephala*); 265. Hispaniolan Spindalis (*Spindalis dominicensis*); 266. Puerto Rican Spindalis (*Spindalis portoricensis*).



Movements. Migratory; entire population moves S to wintering grounds in mountains and Pacific slope (not Caribbean slope) from C Mexico S to extreme NW Costa Rica, a few S to W Panama. Spring migrants reach S Arizona and New Mexico by c. 20 Apr, coastal migrants advancing more swiftly than those inland; by c. 20 May migrants have reached S British Columbia and begun nesting, while those in Rocky Mts plains region are little farther N than NE Colorado; in Montana (Bozeman), birds set off S from c. 27 Aug to 25 Sept.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common over large breeding range. Breeds in many national forests and other protected areas. Breeding range also encompasses extensive intact habitat that, although not formally protected, is at relatively low risk. Wintering habitat also encompasses a variety of protected areas, including in Mexico Cumbres de Majalca (Chihuahua), La Michilía Biosphere Reserve (Durango) and Sierra de Manantlán (Jalisco); also Celaque National Park, in Honduras, and probably Miraflor Natural Reserve and Bosawás Biosphere Reserve, in Nicaragua. Wintering range, which is mostly in foothills and highlands, also contains intact habitat that is not formally protected, but deforestation and fragmentation are locally extensive and it is difficult to assess the long-term viability of these areas. Nevertheless, the species appears to be at little imminent risk on wintering grounds, as it also is able to exploit a variety of disturbed or altered habitats, including shade (but not sun) coffee plantations and selectively logged pine–oak woodlands.

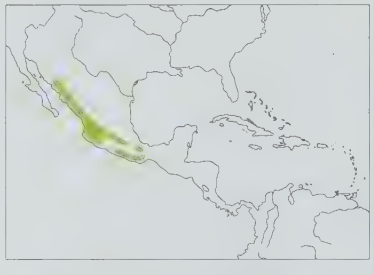
260. White-winged Tanager

Piranga leucoptera

French: Piranga bifascié **German**: Weißbindentangare **Spanish**: Piranga Aliblanca

Taxonomy. *Pyranga leucoptera* Trudeau, 1839, Mexico.
Molecular-genetic evidence indicates that this genus forms a monophyletic group with *Habia* and *Chlorothraupis*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. This species and *P. erythrocephala* have sometimes been placed in a separate genus, *Spermagra*, but recent DNA work does not support such treatment. Four subspecies recognized.
Subspecies and Distribution.
P. l. leucoptera Trudeau, 1839 – highlands of E Mexico (from Tamaulipas) S to Guatemala, Belize, El Salvador, Honduras and Nicaragua.
P. l. latifasciata Ridgway, 1887 – highlands of Costa Rica and W Panama (E to Veraguas).
P. l. venezuelae J. T. Zimmer, 1947 – Andes of Colombia (except Nariño), and highlands of Venezuela (N & S of R Orinoco) and adjacent Brazil (on Uei-tepui).
P. l. ardens (Tschudi, 1844) – W slope of Andes in SW Colombia (Nariño) S to SW Ecuador; E slope from Ecuador and Peru S to Bolivia (to Cochabamba).



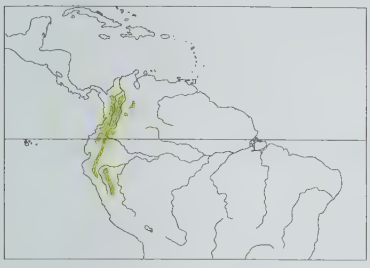
Descriptive notes. 13 cm; 13–20 g. Small stout-billed *Piranga* with conspicuous white wingbars. Male nominate race is mainly bright red, with narrow black line across base of forehead, ocular area and chin (forming small mask); scapulars, upperwing-coverts, flight-feathers, tertials and tail black, tertials sometimes very narrowly tipped white (inconspicuous arcs); median and greater wing-coverts tipped white, forming two bold white wingbars (size of bars varies); often some blackish mottling on back; iris dark brown; bill blackish, basally bluish-grey, especially on lower mandible; legs dark grey. Female has head yellowish-olive, dusky lores and ocular area forming small inconspicuous mask; upperparts slightly darker yellowish-olive, upperwing-coverts dusky black, median and greater coverts broadly tipped white (two conspicuous white wingbars), flight-feathers and tertials dusky, edged dull olive-yellow, tertials usually narrowly tipped white; tail dusky olive-yellow; yellow below, brightest on throat and undertail-coverts, tinged olive on sides and flanks. Juvenile is like female, but duller, juvenile male with blacker flight-feathers; immature male like adult, but underparts duller; subadult male more orangish than red, especially on belly and flanks. Race *latifasciata* male differs from nominate in broader white wingbars and darker red plumage (upperparts close to carmine), female broader white wingbars and more intense yellow and olive; *venezuelae* male differs from nominate primarily in having black of face restricted to lores and orbital ring (no black line over bill); *ardens* is similar to last, but both sexes have lower wingbar (tips of greater coverts) narrower. Voice. Song a thin, wiry "e-seé-se-whéét". In Mexico utters a stream of squeaks and twitters with occasional emphatic squeal. Frequently heard calls often the first indication of this species' presence. In Andes a distinctive "pit-sweet!" or "pit-sweet-sweet!", the "sweet" notes musical and rising; also various sharp "weet" and "chip" notes.
Habitat. In Mexico and N Central America occurs in pine–oak (*Pinus–Quercus*) associations and shady coffee plantations. In lower Central America and in Andes and tepuis occurs in canopy of humid montane forest, cloudforest, tall second-growth woodland, coffee plantations, and drier more seasonal mountain forest, especially drier areas where forest is broken or disturbed. In mature forest found mainly on top of canopy. At c. 100–1800 m in Mexico (mostly above 600 m on Atlantic slope), 1100–1850 m in Costa Rica, and 900–1800 m in Panama; in Venezuela 650–2100 m N of R Orinoco and, S of it, 1000–1800 m; c. 600–2000 m in Colombia, Ecuador and Peru.
Food and Feeding. Fruit, including melastome berries and *Heliocarpus* (Tiliaceae) seeds; probably also some insects. Pairs and groups of 3–6 individuals, calling frequently, usually forage in semi-open on top or outer edge of canopy foliage, either alone or with mixed-species flocks; fairly easy to see. Usually forages somewhat above other species. Peers and flutters in high outer twigs and foliage; looks under small branches in manner of some *Tangara* species.
Breeding. A small cup nest 14 m up on mossy branch, built by female. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common locally in mature montane forest, and second growth and partly wooded areas. Found in numerous parks, reserves and other protected areas, e.g. Celaque National Park (Honduras), La Amistad International Park (Costa Rica and Panama), Henri Pittier and Canaima National Parks (Venezuela), Farallones de Cali and Munchique National Parks (Colombia), Manu Biosphere Reserve (Peru) and Amboró National Park (Bolivia). Range also encompasses extensive intact habitat not formally protected, but at relatively low risk. Has suffered range contraction and fragmentation to varying degrees owing to deforestation, but the species' long-term viability seems secure so long as protected areas within its range are maintained.
Bibliography. Binford (1989), Blake (1953), Burns (1998a), Collins & Watson (1983), Davis (1972), Dickey & van Rossem (1938), Donegan & Dávalos (1999), Edwards (1972), Garrigues & Dean (2007), Ginés *et al.* (1951), Hartman & Brownell (1961), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995), Hubbard (1965), Isler & Isler (1999), Klicka *et al.* (2007), Land (1970), Lysinger *et al.* (2005), Mec *et al.* (2002), Meyer de Schauensee (1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Moore *et al.* (1999), Phelps & Phelps (1950, 1963), Remsen, Cadena *et al.* (2010), Remsen, Traylor & Parkes (1987), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Russell (1964), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Salaman, Stiles *et al.* (2002), Schäfer & Phelps (1954), Schulenberg (2000a), Schulenberg *et al.* (2007), Slud (1964), Smithe (1966), Souza (2002), Stiles & Skutch (1989), Tashian (1953), Wetmore (1939), Wetmore *et al.* (1984), Zimmer (1947a).

261. Red-headed Tanager

Piranga erythrocephala

French: Piranga érythrocéphale **German**: Rotkopftangare **Spanish**: Piranga Cabecirroja

Taxonomy. *Spermagra erythrocephala* Swainson, 1827, Temascáltepec, Mexico.
Molecular-genetic evidence indicates that this genus forms a monophyletic group with *Habia* and *Chlorothraupis*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. This species and *P. leucoptera* have sometimes been placed in a separate genus, *Spermagra*, but recent DNA work does not support such treatment. Two subspecies recognized.
Subspecies and Distribution.
P. e. candida Griscom, 1934 – NW Mexico from S Sonora and S Chihuahua S to Jalisco; outside breeding season recorded S to Michoacán and México.
P. e. erythrocephala (Swainson, 1827) – SC & S Mexico (Jalisco S to E Oaxaca at Isthmus of Tehuantepec).



Descriptive notes. 15 cm; 19·9–24·5 g. Male nominate race has black lores and narrow black eyering, rest of head (except rear crown), throat and foreneck geranium-red, ending in short crest at rear, with faint white markings on ear-coverts; rear crown, nape, rear side of neck, and upperparts, including scapulars, bright yellowish-olive; upperwing-coverts and flight-feathers dusky, broadly edged yellowish-olive, tail yellowish-olive; chest and breast to undertail-coverts olive-yellow, brighter and paler than upperparts; iris brown; bill dusky, basal half of lower mandible blue-grey; legs grey. Female has forecrown yellowish, becoming yellow-olive on rest of crown and upperparts; lores and ear-coverts dusky, throat and chest yellow, becoming whitish to buffy white on belly and undertail-coverts; wings and tail as on male. Juvenile male is similar to female, but brighter. Race *candida* is very similar to nominate, but tends to be slightly duller and darker, with white markings on ear-coverts often more prominent. Voice. Song a long, slow, throaty series of single or double notes, e.g. "chur chew che-wier chéé-chur wee chur cheer chéé-chur..." and so on; also described as a high, thin, fairly rapid, tinkling "tsi-tsi tsee-tsee", or similar variation, the first phrase often repeated up to three times. Call a high "chit" and twittering "chit-t-t-t"; also "spik" or "spi."
Habitat. Semi-humid and moist montane forest and pine–oak (*Pinus–Quercus*) associations, semi-deciduous and evergreen forest, and open woodland mixed with scrub; also forest edges and plantations. From 900 m to c. 2600 m.
Food and Feeding. Insects and small fruits, including blackberries (*Rubus*) and berries of a *Solanum*. Forages in pairs and small groups (possibly family parties), from eye level in shrubs up to canopy, more often at middle levels or higher in medium-sized trees. Inconspicuous; tends to remain within foliage, sometimes in view, as it forages out along ends of branches.
Breeding. Nest a cup of fine twigs and other plant material, at middle heights or high in outer canopy of tree. No other information.
Movements. Some southward movements within Mexico during non-breeding season; seasonal elevational movements also likely.
Status and Conservation. Not globally threatened. Locally fairly common along almost entire Pacific slope of Mexico. Occurs in a number of protected sites, including Cumbres de Majalca National Park (Chihuahua), La Michilía Biosphere Reserve (Durango), Sierra de Manantlán Biosphere Reserve (Jalisco), and almost certainly other reserves. Range also encompasses intact habitat that is not formally protected in S Sonora, Sinaloa, Nayarit, Jalisco, Michoacán and elsewhere. Although the long-term viability of habitat in these areas is unknown, it seems certain that the near-term risk to this species is low.
Bibliography. Alden (1969), Binford (1989), Burns (1997a), Burns *et al.* (2002, 2003), Davis (1972), Edwards (1972), Griscom (1934), Hellmayr (1936), Howell & Webb (1995), Hutto (1980), Isler & Isler (1999), Peterson & Chalif (1973), Rowley (1966), Salvin & Godman (1883), Schaldach (1963, 1973), Zimmerman & Harry (1951).

262. Red-hooded Tanager

Piranga rubriceps

French: Piranga à capuchon **German**: Scharlachkopftangare **Spanish**: Piranga Capuchirroja
Other common names: Gray's Tanager

Taxonomy. *P.*[*yranga*] *rubriceps* G. R. Gray, 1844, "Bogotá".
Molecular-genetic evidence indicates that this genus forms a monophyletic group with *Habia* and *Chlorothraupis*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. Monotypic.
Distribution. Locally in all three ranges of Andes in Colombia, and on E slope (from Nariño and Putumayo) S through Ecuador (locally also on W slope S to Pichincha) to N Peru (S to Huánuco).
Descriptive notes. 17 cm; 28–42 g. Colourful stout-billed tanager with red head and yellow underparts. Male has entire head down to upper mantle and to central breast deep red, back and scapulars yellowish-olive, becoming bright yellow on rump and most of uppertail-coverts; longest uppertail-coverts olive, rather like tail, which slightly darker dusky olive with dull yellow edgings; bend of wing and lesser and median upperwing-coverts bright yellow (often partly or

completely hidden), rest of wing and tail black with olive-yellow fringes on greater coverts and outer webs of tertials, secondaries and rectrices; underparts from chest to undertail-coverts bright yellow; iris dark brown; bill blackish; legs dark grey. Female is similar to male but duller, with red more restricted, reaching only as far as upper nape and foreneck. Juvenile undescribed. VOICE. Song a combination of thin trills, e.g., "tititi-titi", interspersed with sweeter, more musical phrases such as "tswe, weéteetseet-see". Also gives sharper, more piercing "tsee-ee-ee-ee" or similar note that rises, e.g. "tuueeet!". Calls include sharp "spink!" and "tink!" notes.

Habitat. Found in humid and wet montane forest, especially mossy epiphyte-laden forests, and forest edges. At 1700–3000 m in Colombia; mostly 2200–3000 m in Ecuador; c. 1800–3000 m in Peru.

Food and Feeding. Forages in pairs and in small groups of 3–6 individuals; with mixed-species flocks or away from them about equally. Hops and peers sluggishly along limbs or in foliage in middle or upper storey; often in open, where fairly conspicuous.

Breeding. Female in breeding condition in Sept at N end of W Andes. No other information.

Movements. Apparently resident.

Status and Conservation. Not globally threatened. Rare to uncommon and local; almost everywhere throughout limited Andean range occurs at low density. Can be found in a number of protected areas, including Las Orquídeas, Tatamá and Cueva de los Guácharos National Parks (Colombia), the Reserva Hidrográfica de Río Blanco, in Caldas (Colombia), Antisana and Cayambe-Coca Ecological Reserves and Sangay and Podocarpus National Parks (Ecuador), and Cordillera Azul National Park (Peru). Range encompasses intact forest in unprotected areas, although portions of this may be at near-term risk. The long-term viability of this species seems secure so long as the parks and reserves where it occurs are maintained. It has, however, suffered considerable range contraction and fragmentation, and these will probably continue to take place.

Bibliography. Clements & Shany (2001), Echeverry-Galvis & Córdoba-Córdoba (2007), Fjeldså & Krabbe (1990), Graves (1983), Hilty & Brown (1983, 1986), Isler & Isler (1999), Krabbe *et al.* (2001), Meyer de Schauensee (1964, 1966, 1970a), Moynihan (1979), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schulenberg *et al.* (2007), Zimmer (1945, 1947a).

Genus *SPINDALIS* Jardine & Selby, 1837

263. Western Spindalis

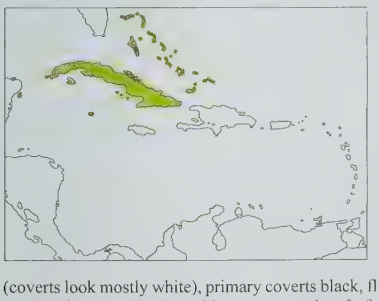
Spindalis zena

French: Zéna à tête rayée **German**: Kuba-Streifenkopftangare **Spanish**: Cigua Cubana
Other common names: (Western) Stripe-headed Tanager; Bahaman Spindalis (nominate and *townsendi*); Cuban Spindalis (*pretrei*); Cayman/Salvin's Spindalis (*salvini*); Benedict's/Cozumel Spindalis (*benedicti*)

Taxonomy. *Fringilla Zena* Linnaeus, 1758, New Providence, Bahama Islands.

Recent molecular-genetic studies suggest that this genus and *Nesospingus*, *Chlorospingus* and *Phaenicophilus* form a monophyletic clade that is sister to several New World warbler (Parulidae) genera (including *Dendroica*, *Basileuterus* and *Vermivora*), and are not closely related to other genera of present family. This species forms a superspecies with *S. nigricephala*, *S. dominicensis* and *S. portoricensis*; all four were formerly treated as conspecific, but differ in morphology, plumage and vocalizations, and are geographically isolated from one another. Moreover, races of present species originally suggested as representing four distinct species, nominate and *townsendi* forming one species and *pretrei*, *salvini* and *benedicti* a further three. Additional studies may lead to changes in the present taxonomic arrangement. Five subspecies currently recognized.

Subspecies and Distribution.



S. z. townsendi Ridgway, 1887 – N Bahamas (including Grand Bahama, Little Abaco, Abaco and offshore cays).

S. z. zena (Linnaeus, 1758) – C & S Bahamas (including Berry Is, Andros, Green Cay, New Providence, Eleuthera, Cat I, Exuma, Long I, Acklin and Mayaguana).

S. z. pretrei (Lesson, 1831) – Cuba and I of Pines.

S. z. salvini Cory, 1886 – Grand Cayman I.

S. z. benedicti Ridgway, 1885 – Cozumel I, off NE Yucatán Peninsula.

Descriptive notes. 15 cm; 17–25·5 g (nominate), 18–25·5 g (*pretrei*), 20·5–31 g (*salvini*), 26·5–35·6 g (*benedicti*). Smallest spindalis, bill short and conical. Male nominate race has head and side of throat black, long white supercilium, broad white submoustachial area, white chin, bright yellow central throat; nuchal collar and chestband chestnut and rich yellow; mantle and upper back black, lower back tawny-yellow, rump and shorter uppertail-coverts darker golden-rufous, longer uppertail-coverts black; tail black with extensive white outer edges; scapulars and upperwing-coverts black, greater coverts with outer webs almost entirely white (coverts look mostly white), primary coverts black, flight-feathers and tertials black, small white patch at base of outer primaries (white on outer webs of a few feathers), otherwise flight-feathers sharply and narrowly edged with white, tertials more broadly edged white; mid-breast yellow, turning white on lower underparts; iris dark brown; bill blackish, basal half to two-thirds of lower mandible and base of upper mandible steel-grey; legs dark grey. Female is greyish-olive above, with obscure whitish submoustachial; rump and uppertail-coverts paler brown than back, greater wing-coverts dusky, broadly edged whitish, flight-feathers dusky, narrowly edged whitish-olive, tertials dusky black, broadly edged whitish-olive, outer primaries with small white spot at base of feathers; tail dull olive-grey; throat and underparts unstreaked dirty greyish to buffy whitish. Juvenile is similar to female but much duller, with minimal pattern on foreparts. Race *townsendi* male differs from nominate in having nuchal collar tawny-rufous (not tawny), back dark olive-green mixed with dusky brown, lower back darker tawny-orange, scapulars duller, more dusky; *pretrei* male differs in bright olive-green back, brighter rump, paler tawny-yellow nuchal collar, paler tawny on chest, chestnut on lesser wing-coverts, median coverts broadly tipped olive-green, female differs in having long dull whitish supercilium, some yellow on underparts, and often a weak greyish malar stripe; *salvini* male is much like previous, but slightly larger, rump slightly darker, nuchal collar and chestband darker (more tawny-orange), and more extensively white on flanks and lower underparts; *benedicti* male most closely resembles nominate, but back deep yellowish-olive, scapulars sometimes partly blackish, lesser upperwing-coverts chestnut, and median coverts black, tipped with yellowish-olive. VOICE. Song high, thin, sibilant and rather variable, e.g. "see-tee" doublets mixed with high "seet" and reedy "deet" notes and sometimes with twittering notes; weak, but stronger during breeding season and usually delivered from top of high tree. A second song type described as a soft warbling series of notes given rapidly. Flight song a high, sibilant "seeet sit-t-t-t-t". A faint whisper song also described. High, thin quality of vocalizations often makes this bird difficult to locate. Calls include high thin "seeip" and soft "tsit-tsit-tsit".

Habitat. Lowlands to highlands, in wide range of fairly dry to humid regions. In Bahamas found in native pines (*Pinus*) and Australian pines (*Casuarina*) when breeding, and at other times can occur in almost all habitats, including scrub and densely vegetated habitats (coppice). On Cuba and I of Pines occurs from coast to mountains in open woodland, brushland, forest edges, second growth and mangroves, but not inside tall dense forest. Most numerous at middle and higher elevations. On Cozumel I mainly in disturbed, degraded and second-growth vegetation.

Food and Feeding. Feeds mainly on fruits and berries, also tips of soft leaves and other plant parts; once seen attempting to eat a snail (Gastropoda). In pairs when breeding; at other times in pairs and small groups, in past apparently also in larger groups. Forages from low in shrubs to high in trees.

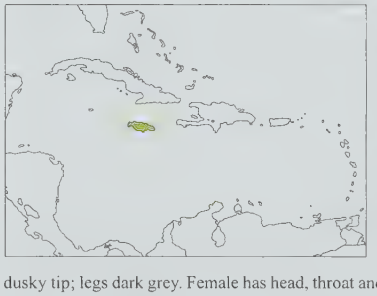
Breeding. Season Apr–Aug. In flight display, male flies up on slowly beating wings, circles above treetops while singing, then dives down to same or another perch; spread wing and tail feathers may make a noise during display. Thin, poorly constructed nest of palm fibres, placed low down or quite high up in bush or small to large tree. Clutch 2–3 eggs, white, covered with brownish dots. No other information.

Movements. Resident, with some inter-island wandering. Occasional records at various extralimital localities. Up to c. 50 records (some unverifiable) from S Florida (SE USA), in all months except Jul, with greatest concentration in Apr, May and Dec (which may represent periods when more human observers afield); estimated 65% of Florida records are of males.

Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Considered common in Bahamas and Cuba, fairly common on Grand Cayman I, and in small numbers on numerous other islands. Utilizes a variety of second-growth, disturbed and scrubby habitats, which buffers it against threats. In past reported to occur in large groups on Cuba, but populations there may have been much depleted as a result of trapping.

Bibliography. Acosta *et al.* (2003), Barbour (1943), Bond (1943, 1956, 1985), Brudenell-Bruce (1975), Buden (1980, 1987), Burns (1997a), Burns *et al.* (2002, 2003), Davis (1972), Downer & Sutton (1990), Edwards (1972), English (1916), Garrido & Montaña (1975), Garrido *et al.* (1997), Griscom (1926), Gundlach (1855), Hellmayr (1936), Howell & Webb (1995), Isler & Isler (1999), Klaas (1968), Oberle (2008), Olson & Angle (1977), Paynter (1955), Pranty & Smith (2001), Raffaele *et al.* (1998), Reynard (1969, 1982), Sibley (2000), Steadman *et al.* (1980).

264. Jamaican Spindalis



Spindalis nigricephala

French: Zéna de Jamaïque **German**: Jamaika-Streifenkopftangare **Spanish**: Cigua Jamaicana
Other common names: Jamaican (Stripe-headed) Tanager

Taxonomy. *Tanagra nigricephala* Jameson, 1835, Jamaica.

Recent molecular-genetic studies suggest that this genus and *Nesospingus*, *Chlorospingus* and *Phaenicophilus* form a monophyletic clade that is sister to several New World warbler (Parulidae) genera (including *Dendroica*, *Basileuterus* and *Vermivora*), and are not closely related to other genera of present family. This species forms a superspecies with *S. zena*, *S. dominicensis* and *S. portoricensis*; all four were formerly treated as conspecific, but differ in morphology, plumage and vocalizations, and are geographically isolated from one another. Further taxonomic evaluation may be warranted. Monotypic.

Distribution. Jamaica.

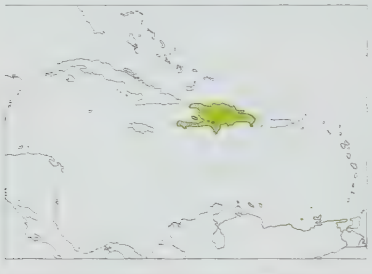
Descriptive notes. 18 cm; 38–64·8 g. Largest spindalis. Male has black hood with long, broad white supercilium reaching to side of nape, and long, broad white submoustachial stripe, with white also on chin and upper throat; yellowish-olive back, tawny-yellow rump and uppertail-coverts; wing and tail black, with greater upperwing-coverts, flight-feathers and sides of outer tail feathers heavily edged white; central chest bright yellowish-orange becoming yellow below, with greenish-golden tinge on sides and flanks, rearmost belly, thighs and undertail-coverts white; iris dark brown; bill dusky above, lower mandible steel-grey with dusky tip; legs dark grey. Female has head, throat and upperparts greyish-olive (facial stripes obscure or absent); white edging on greater wing-coverts and inner flight-feathers; pale orange-yellow central chest, becoming pale yellow on belly and whitish on undertail-coverts. Juvenile resembles female but much duller, with black markings on head obscure. VOICE. Notably quiet. A long-sustained whisper song consisting of a phrase c. 4 seconds long repeated over and over, e.g. "chu wheet, chee see whee see, chu wheet". Gives soft "seep" notes, often heard in flight, and a high, fast "chi-chi-chi-chi-chi" when foraging in groups. Male gives churrs or rattles when disturbed or in hostile situations; a female gave a harsh "chirring" note when gathering nesting material.

Habitat. Forest, woodlands and brushy areas; mainly fruiting trees and shrubs in forest and forest borders. Lowlands and highlands; much more numerous in hills and mountains. Local on N and SW coasts.

Food and Feeding. Fruit and berries, including many non-native species such as oranges, pimentos, and royal palm (*Roystonea*) fruits; other fruits in diet include *Ficus*, *Cecropia* and *Dunalia*, and has been noted as eating leaves and orange blossoms. Two stomachs contained fruit seeds. Pairs and family groups often at fruiting trees; also gathers in feeding aggregations of 8–10 individuals, which interact with much chattering and scolding. Acrobatic, hanging in various positions from twigs to take berries. Rests in treetops.

Breeding. Season Apr–Jul. Nest a loose cup of grass and rootlets. Clutch 2–3 eggs, greenish-white or pale grey, marked with brown or grey, especially around larger end. No other information.

Movements. Resident.



Status and Conservation. Not globally threatened. Restricted-range species: present in Jamaica EBA. Common and widespread, particularly at higher elevations. Utilization of a variety of habitats, including second growth and brushy areas, safeguards this species against near-term threats, despite its tiny global range.
Bibliography. Bond (1943, 1956, 1985), Cruz (1974), Danforth (1928), Downer & Sutton (1990), Garrido *et al.* (1997), Gosse (1847), Hellmayr (1936), Isler & Isler (1999), Jeffrey-Smith (1956), March (1863), Ogilvie-Grant (1912), Raffaele *et al.* (1998), Reynard (1969, 1982), Steadman *et al.* (1980), Taylor (1955).

265. Hispaniolan Spindalis

Spindalis dominicensis

French: Zéna d'Hispaniola **Spanish**: Cigua de la Española
German: Hispaniola-Streifenkopftangare
Other common names: Hispaniolan (Stripe-headed) Tanager

Taxonomy. *Tanagra dominicensis* H. Bryant, 1867, Port-au-Prince, Haiti.
Recent molecular-genetic studies suggest that this genus and *Nesospingus*, *Chlorospingus* and *Phaenicophilus* form a monophyletic clade that is sister to several New World warbler (Parulidae) genera (including *Dendroica*, *Basileuterus* and *Vermivora*), and are not closely related to other genera of present family. This species forms a superspecies with *S. zena*, *S. nigricephala* and *S. portoricensis*; all four were formerly treated as conspecific, but differ in morphology, plumage and vocalizations, and are geographically isolated from one another. Present taxonomic arrangement may warrant further evaluation. Monotypic.
Distribution. Hispaniola (Haiti and Dominican Republic) and Gonâve I.

Descriptive notes. 16·5 cm; 25–33·2 g. Male has black head with long, broad white supercilium and submoustachial area, chin white, bright yellow patch on central throat flanked by black triangle on lower part of malar area; rich yellow hindneck, mantle and back rather green citrine-olive, darker on scapulars, rump tawny-yellow becoming chestnut on uppertail-coverts, lower tail-coverts black; marginal and lesser upperwing-coverts deep chestnut, median coverts black with deep olive edges, greater coverts black, prominently edged white (most of outer web of each feather white); flight-feathers and tail black, narrowly edged white, tertials more broadly edged white, white spot at base of outer primaries; central chest broadly deep chestnut, becoming yellower on sides and bright rich yellow on breast, light greyish on flanks, white from central belly to undertail-coverts; iris dark brown; bill dusky, basal half of lower mandible steel-grey; legs dark grey. Differs from similar *S. nigricephala* in smaller size, yellow nuchal collar, and small rufous shoulder patch (marginal and lesser coverts). Female is greyish-olive overall, greyer on rather uniform head and mantle, yellower on rear upperparts, upperwing dusky brown with buffy-olive feather edges, lesser and median coverts mostly dull olive, primary coverts blackish-brown, tail feathers dusky-brown with olive outer edges; malar area and throat whitish with ill-defined dusky spots, a hint of dusky malar stripe in between, rest of underparts whitish with ill-defined dusky streaks, whitest on belly and undertail-coverts. Juvenile similar to female but much duller, with black on head obscure. Voice. Dawn song described as a thin, high-pitched whistle, or a prolonged weak, sibilant "tsee see see see". Male sings from exposed perch or lower and inside dense thickets. Female sings a whisper song of jumble notes recalling that of male. Commonest call a high "thseep"; also gives more drawn-out "seeee", this sometimes followed by ticking notes.
Habitat. Wide range of habitats, but favours humid regions with thickets and low vegetation in or near montane forest, woodland and pine (*Pinus*) forest. Away from forest mainly in orchards and plantations; attracted to fruiting shrubs and trees. Least numerous in overgrown clearings and dry scrub. Lowlands and highlands; most numerous in highlands.
Food and Feeding. Primarily fruits and flower buds, also seeds and tender green leaves, also insects. Fruit comprised 70–93% of foraging records in two studies, and stomach contents have included only fruit. Observed to eat fruits of *Cecropia*, *Miconia*, *Ficus*, *Brunellia*, *Solanum* and *Passiflora*, *Rubus* species (blackberries) and rose apples (*Syzygium jambos*); also pecks or opens oranges and other large fruits. Found in pairs and in small groups of 3–4 individuals; may congregate locally in larger numbers when fruit ripening. Forages from low in bushes to tops of fruiting trees. Takes insects from foliage and on fruit.
Breeding. Season May–Jun; some pairs raise second brood. Small cup-nest, loosely constructed entirely from dry grass, placed 1–4·5 m up in tree or bush. Clutch 3 eggs, whitish with brown spots, mostly on large end. No further information available.
Movements. Resident. Local movements in response to changing fruit supplies.
Status and Conservation. Not globally threatened. Restricted-range species: present in Hispaniola EBA. Common and widespread, particularly at higher elevations; less numerous in lowlands and on coast. Occurs in several parks in Dominican Republic, including Armando Bermúdez and José del Carmen Ramírez National Parks, and in numerous other protected areas, including Sierra de Neiba, Sierra de Bahoruco, La Barbacoa, Montaña de Humeadora and Nalga de Macao. Utilization of a variety of habitats, including second growth and brushy areas, buffers this species against near-term threats, despite its small world range.
Bibliography. Bond (1943, 1956, 1985), Christy (1897), Danforth (1926), Dod (1978), Garrido *et al.* (1997), Hellmayr (1936), Isler & Isler (1999), Raffaele *et al.* (1998), Reynard (1969, 1981), Steadman *et al.* (1980), Verrill & Verrill (1909), Wetmore & Swales (1931).

266. Puerto Rican Spindalis

Spindalis portoricensis

French: Zéna de Porto Rico **Spanish**: Cigua Puertorriqueña
German: Puerto-Rico-Streifenkopftangare
Other common names: Puerto Rican (Stripe-headed) Tanager

Taxonomy. *Tanagra portoricensis* H. Bryant, 1866, Puerto Rico.
Recent molecular-genetic studies suggest that this genus and *Nesospingus*, *Chlorospingus* and *Phaenicophilus* form a monophyletic clade that is sister to several New World warbler (Parulidae) genera (including *Dendroica*, *Basileuterus* and *Vermivora*), and are not closely related to other genera of present family. This species forms a superspecies with *S. zena*, *S. nigricephala* and *S. dominicensis*; all four were formerly treated as conspecific, but differ in morphology, plumage and vocalizations, and are geographically isolated from one another. Present taxonomic arrangement may warrant further evaluation. Monotypic.
Distribution. Puerto Rico.

Descriptive notes. 16·5 cm; male 22·5–37 g, female 28–41·1 g. Male has black head with long, broad white supercilium and submoustachial area, latter with narrow black flecking, chin white, bright yellow to orange patch on central throat flanked by black triangle on lower part of malar area; nape and side of neck yellow-orange to bright orange, mantle and scapulars deep yellowish-olive to olive-green, brighter olive-yellow tinge on rump and shorter uppertail-coverts; tail dusky with narrow yellowish-olive fringes; rufous at bend of wing and on marginal coverts (often hidden), median upperwing-coverts dusky with buff edgings and tips, greater coverts and flight-feathers dusky with narrow yellowish-white edgings; orange of foreneck fades to golden-olive on chest and breast, often greener on sides, most of flanks pale greyish, lower belly to undertail-coverts nearly white, entire abdomen usually with obscure dusky spots or stripes; iris dark brown; bill dusky, basal portion of lower mandible steel-grey; legs dark grey. Differs from similar *S. nigricephala* mainly in smaller size, orangy hindcollar, rufous patch on bend of wing, and less black on lower throat. Female is olive-brown above, tinged greenish-yellow on rump and uppertail-coverts; variable whitish supercilium, submoustachial area dingy whitish; upperwing and tail dusky brown, edged buffy brown to greenish-yellow; chin and central throat whitish, often a yellow to orange spot on central foreneck, rest of underparts pale sandy-buff, with ill-defined dusky streaks mainly on sides and flanks, and often some yellow on central underparts; very like female of *S. dominicensis*, but streaking below clearer, less smudgy, has white head markings, and often some yellowish on central underparts. Juvenile resembles female but much duller, with black pattern on head obscure. Voice. Song a thin, high, squeaky or wiry "zeé-tit-zeé-tittit-´zeé", the "zeé" notes sound like air being inhaled; or a thin high "tswee, tswee, tsweey". Basic call has two variations, a thin trill like a tiny hammer, and a short twittering. Call a soft "teweep", ventriloquial and difficult to locate.
Habitat. Woodland and forest, at all elevations.
Food and Feeding. Feeds mainly on small fruits and flower buds. Occurs in pairs, family parties and locally in larger groups around suitable fruiting trees; may gather in flocks locally when ripe fruit abundant. An arboreal species.
Breeding. Breeds primarily Mar–Jun, sometimes from as early as Dec. Nest a loose cup of vegetation, sometimes with *Usnea* lichen, built low in bush, tree or palm. Clutch 2–4 eggs, pale blue, blotched and scrawled with blackish or dark blue. No other information.
Movements. Resident. Local movements in response to shifting seasonal food supplies, but does not migrate away from the islands.
Status and Conservation. Not globally threatened. Restricted-range species: present in Puerto Rico and the Virgin Islands EBA. Common and widespread. There are 56 nationally recognized protected areas in Puerto Rico, and the species occurs in many of the terrestrial sites, including the well-known Caribbean National Forest/Luquillo Experimental Forest and Guánica State Forest and Biosphere Reserve. Utilization of a variety of habitats, especially second growth and brushy areas, safeguards this species against near-term threats, despite its small world range.

Genus *HABIA* Blyth, 1840

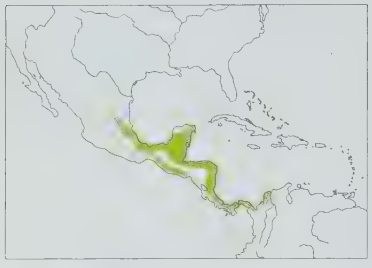
267. Red-crowned Ant-tanager

Habia rubica

French: Habia à couronne rouge **German**: Karminameisentangare **Spanish**: Habia Coronirroja
Other common names: Jungle Ant-tanager

Taxonomy. *Staltator* [sic] *rubicus* Vieillot, 1817, Paraguay.
Molecular-genetic evidence indicates that this genus may form a monophyletic group with *Piranga* and *Chlorothraupis*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. Nominate race and *bahiae* geographically isolated from all other races, in region of SE Brazil; other races are smaller and paler, with more contrasting pattern on head, and might represent a separate species. Several of the numerous races are weakly differentiated and seem barely worth recognizing. Seventeen subspecies currently recognized.
Subspecies and Distribution.
H. r. holobrunnea Griscom, 1930 – E Mexico from S Tamaulipas S to N Oaxaca.
H. r. rosea (Nelson, 1898) – Pacific slope of SW Mexico from Nayarit and Jalisco S to Guerrero.
H. r. affinis (Nelson, 1897) – SW Oaxaca (S Mexico).
H. r. nelsoni (Ridgway, 1902) – SE Mexico (Yucatán Peninsula).
H. r. rubicoides (Lafresnaye, 1844) – S Mexico (from Pueblo, E Oaxaca, Tabasco and Chiapas), Guatemala and Belize S to Honduras, El Salvador and possibly Nicaragua.
H. r. alfaroana (Ridgway, 1905) – NW Costa Rica (Guanacaste).
H. r. vinacea (Lawrence, 1867) – Pacific slope of Costa Rica (S from Nicoya Peninsula) and Panama (E to Darién).
H. r. perijana Phelps, Sr & Phelps, Jr, 1957 – Perijá Mts region of Venezuela–Colombia.
H. r. coccinea (Todd, 1919) – base of Andes in W Venezuela (S from Lara) and adjacent NC Colombia.
H. r. crissalis Parkes, 1969 – NE Venezuela (mountains of Anzoátegui and Sucre).
H. r. rubra (Vieillot, 1819) – Trinidad.
H. r. mesopotamia Parkes, 1969 – E Venezuela (R Yuruán region of E Bolívar).
H. r. rhodinolaema (Salvin & Godman, 1883) – Colombia E of Andes (from Meta S to Caquetá), NW Brazil, E Ecuador and NE Peru.
H. r. peruviana (Taczanowski, 1884) – E Peru, W Brazil and N Bolivia (S to Santa Cruz).
H. r. hesterna Griscom & Greenway, 1937 – C Brazil S of R Amazon (E to R Xingu, S to N Mato Grosso).
H. r. bahiae Hellmayr, 1936 – NE & CE Brazil (Alagoas; SE Bahia).
H. r. rubica (Vieillot, 1817) – E Paraguay, SE Brazil (from S Minas Gerais and Espírito Santo S to Rio Grande do Sul) and NE Argentina (Misiones).

Descriptive notes. 17–19 cm; male 27·7–42·9 g, female 22·5–37 g. Mostly brownish-red ant-tanager with strong bill and no obvious crest. Male nominate race is mainly dull brownish-red above, with partly hidden scarlet crown patch bordered narrowly by inconspicuous black line (crown patch usually shows as narrow medial stripe, and often inconspicuous, but can be raised); upperwing-coverts dull red, primary coverts blackish, narrowed edged red, flight-feathers dusky, inner half of primaries and most of secondaries edged dull red, tertials and tail mostly dull red; paler red below, throat (and sometimes chest) contrastingly brighter red, flanks tinged grey; iris dark brown; bill dusky above, generally paler below; legs dark grey. Female is similar to male but duller, olive-brown above, with brownish-yellow median crown patch; underparts paler than above. Juvenile is generally sooty olive-brown, paler below, and palest on throat; soon acquires immature plumage, which is much like female; adult male plumage gained in about one year. Races differ mainly in brightness of plumage above and below: *bahiae* rather similar to nominate, with red of breast somewhat less extensive; *perijana* is relatively dark, morocco-red above with scarlet crest, throat coral-red, breast dull scarlet, becoming rose-pink on lower underparts and tinged brick-red on flanks; *coccinea* has brightest red (scarlet) throat, blood-red breast and pale jasper-red underparts, generally redder above (although tinged brownish) and with more scarlet crest than other races; *crissalis* resembles previous (has throat deep red), but posterior underparts paler and pinker; *rubra* is duller and with red areas less scarlet than last; *mesopotamia* is paler than nominate, abdominal area greyish, undertail-coverts more salmon-pink (less rose-pink), dark margins of red crown patch less well marked or even absent, and bill paler, upper mandible brown (rather than blackish); *rhodinolaema* has rosy-red throat, and breast and belly washed grey; *rosea* is palest, with upperparts pinkish-red and underparts pale pinkish-red; *affinis* and *nelsoni* resemble last; *holobrunnea* darker above than nominate, slightly paler and redder below; *hesterna* slightly smaller than nominate and generally paler, especially on underparts; *rubicoides* is darker, with upperparts dull dark red, and red throat contrasting slightly with dusky red underparts; *vinacea* and *alfaroana* resemble preceding race. Voice. Has diverse array of vocalizations, some harsh, some exceptionally melodic. In Middle America three main song types: breeding-season dawn song by male, varying individually, may be e.g. "peer peer p"yerk pewk peer", or a series of musical, mostly trisyllabic phrases, e.g. "inter-vene, inter-vene..." and so on; day song, likely to be rough or burry and more repetitive (so far, reported mainly from Mexico to Belize); and whisper song mainly during day, may be given when carrying food, in territorial disputes and at other times. In South America dawn and day songs are quite variable from region to region, and may include only sweet, melodic phrases or, more often, a mixture of harsh and melodic phrases. Call notes in all areas are harsh "chat" or "chak" notes and other grating sounds, sometimes in chattering or rough series.
Habitat. Leafy undergrowth and lower levels of humid *terra firme* forest and tall second growth; also *várzea* and transitional forest in Amazonia. Occurs almost exclusively in forest interior, infrequently along river edges or forest borders. Lowlands to 1500 m in El Salvador; to c. 1200 m in Costa Rica and to 2250 m in Panama; to 1400 m in Venezuela, 500 m in Colombia, 600–700 m in Ecuador and c. 900 m in Peru.
Food and Feeding. Food primarily arthropods; small amount of fruit, including *Miconia* and *Solanum* berries. Of 24 stomachs examined, two contained only vegetable matter and 18 only animal matter and four contained both; contents included weevils (Curculionidae) and other beetles (Coleoptera), ants (Formicidae), caterpillars, millipedes (Diplopoda), mantises (Mantodea), snails (Gastropoda), berries and fruit. Nestling diet larvae and mature insects, some so large that young have difficulty in swallowing them. Lives in pairs and small family groups, and sometimes joined by other species, but typically wary and difficult to see. In N Central America may defend a common territory with Tawny-crowned Greenlet (*Hylophilus ochraceiceps*), the two species forming core of small mixed-species flocks; foraging territory in Belize c. 4–5 ha, and family-members may forage together along territorial boundaries when not breeding. In Amazonia, associates with a few other species in small understorey flocks and travels independently of them about equally. Follows army-ant swarms in Central America and Trinidad, but faithfulness to swarms varies; in Amazonia seldom follows army ants, but regularly reported at swarms in SE Brazil (Espírito Santo). Forages from near ground to c. 10 m up, infrequently higher. Mean foraging height in SE Peru was c. 3·6 m. Forages by hopping in foliage, or occasionally leaping or fluttering and lunging for prey, which it picks off twigs and foliage or captures in chasing manoeuvres. Rarely, captures prey by sallying. May hover or cling momentarily beneath a leaf or other substrate to capture an insect, and regularly searches hanging dead leaves. In Trinidad forages mostly on branches and twigs. May take fruit while perched or in short fluttering sally, and occasionally takes fallen fruit from ground.
Breeding. Breeding reported May and Jun (less often as early as Feb) in Mexico, Apr–Jul in Belize, Mar in Guatemala and Feb–Jun in Costa Rica; Feb–Aug (also Oct) in Trinidad; in Brazil, Feb and Apr in Pará and Sept–Dec in Rio de Janeiro; at least Sept through Jan in Paraguay; occasionally two broods. Pair defends a breeding territory. Nest built almost entirely by female, a shallow cup-shaped structure of rootlets, plant fibres and twigs, usually markedly thin-walled (eggs often visible from outside), but one nest in Paraguay thick-walled, placed 1–4 m (infrequently to 7 m) above ground in fork of sapling, bush or vine inside forest, often near small stream. Clutch 2 or 3 eggs, rarely 1 or 4, white or bluish with cinnamon or yellow-brown spots, especially at large end, where form a wreath; incubation by female, period 13–14 days; chicks fed by both adults, females feeding more than males; adults may engage in distraction displays, feigning injury, to lead intruders away from nest; nestling period c. 10 days; young leave nest before able to fly, and hop about in thick foliage and bushes.
Movements. Resident.
Status and Conservation. Not globally threatened. Widespread, and uncommon to locally fairly common. Occurs in a large number of parks and reserves throughout its large range, and its numerous populations, many of which are geographically isolated, face variety of environmental conditions. Deforestation extensive within the range of populations from Mexico S to NW Colombia and, while unprotected lowland forest remains in Guatemala, Belize and Nicaragua, the species appears to be largely confined to protected areas and parks in much of its area of distribution in Mexico, El Salvador, Costa Rica and Panama. Large Amazonian population widespread and is at little risk. Populations in E & SE Brazil appear to be largely confined to a string of parks and reserves; some in SE Brazil reported as surviving in remnant woodlots as small as 21 ha. Those in Andean foothills of Venezuela and NE Colombia have contracted with deforestation but remain viable in numerous areas, including shade coffee plantations. Status of populations in NE Venezuela uncertain, but deforestation is extensive and ongoing in this area, and likely that few birds persist away from the few protected areas, such as Cueva del Guácharo and Península de Paria National Parks.
Bibliography. Allen (1905), Álvarez del Toro (1952), Beebe (1909), Belcher & Smooker (1937), Belton (1985), Burns (1997a), Burns *et al.* (2002, 2003), Clements & Shany (2001), Diamond & Lovejoy (1985), Dickey & van Rossem (1938), Dunning (1982), Edwards (1972), Euler (1867), ffrench (1991), Foster *et al.* (1989), Garrigues & Dean (2007), Hartman (1955), Herklots (1961), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995), Isler & Isler (1999), Klicka *et al.* (2007), Land (1970), de Lima Fávaro & dos Anjos (2005), Meyer de Schauensee (1964, 1966, 1970a), Munn & Terborgh (1979), Narosky & Di Giacomo (1993), Nehrkorn (1899), Ogilvie-Grant (1912), Parker & Goerck (1997), Parkes (1969b), Paynter (1955), de la Peña & Rumboll (1998), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Rowley (1966), Russell (1964), Salaman *et al.* (2008), Schubart *et al.* (1965), Schulenberg (2000c), Schulenberg *et al.* (2007), Sick (1985, 1993), Skutch (1954, 1980b), Slud (1964), Smithe (1966), Snethlage & Schreiner (1929), Souza (2002), Stiles & Skutch (1989), Tashian (1952), Weske (1972), Wetmore *et al.* (1984), Willis (1960a, 1960b, 1960c, 1961, 1972, 1979, 1980), Zimmer (1945).



268. Red-throated Ant-tanager

Habia fuscicauda

French: Habia à gorge rouge **German**: Rotkehl-Ameisentangare **Spanish**: Habia Gorjirroja
Other common names: Jungle Ant-tanager; Salvin's Ant-tanager (*salvini*)

Taxonomy. *Phoenicothraupis fuscicauda* Cabanis, 1861, Costa Rica.
Molecular-genetic evidence indicates that this genus may form a monophyletic group with *Piranga* and *Chlorothraupis*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. Race *willisi* appears to intergrade with nominate in NW Panama, from where one specimen is intermediate between the two. Six subspecies recognized.
Subspecies and Distribution.
H. f. salvini (Berlepsch, 1883) – E & SE Mexico (from San Luis Potosí and S Tamaulipas) S to Guatemala (except N), Belize, Honduras and El Salvador.
H. f. insularis (Salvin, 1888) – SE Mexico (N & E Yucatán Peninsula) and N Guatemala.
H. f. discolor (Ridgway, 1901) – Nicaragua.
H. f. fuscicauda (Cabanis, 1861) – extreme S Nicaragua, and both slopes of Costa Rica S to W Panama.
H. f. willisi Parkes, 1969 – C Panama from NE Coclé and Colon E to San Blas (mainly on Caribbean slope).
H. f. erythrolaema (P. L. Sclater, 1862) – Caribbean coast of Colombia (N Atlántico, N Bolívar and Córdoba).
Descriptive notes. 18–20 cm; 29–46·5 g. Dark ant-tanager with strong bill. Male nominate race has head dull dark red, with usually concealed scarlet crown patch and dusky lores; upperparts dusky brown, tinged red; upperwing-coverts dark dull red, flight-feathers dusky, edged dull red, tertials and tail dull red to brownish-red; throat intense rose-scarlet, contrasting with dusky side of head and dusky reddish-brown breast; lower underparts dark greyish-brown with faint reddish tinge;

On following pages: 269. Black-cheeked Ant-tanager (*Habia atrimaxillaris*); 270. Sooty Ant-tanager (*Habia gutturalis*); 271. Crested Ant-tanager (*Habia cristata*); 272. Carmiol's Tanager (*Chlorothraupis carmioli*); 273. Olive Tanager (*Chlorothraupis frenata*); 274. Lemon-spectacled Tanager (*Chlorothraupis olivacea*); 275. Ochre-breasted Tanager (*Chlorothraupis stolzmanni*).

iris dark brown; bill dusky; legs brownish-flesh. Female is dark brown above, paler below, with contrasting ochre-yellow throat. Juvenile is overall dingy and dark, mostly sooty cinnamon-brown, but soon moults into immature plumage; immature much like female, male acquires adult plumage at c. 1 year of age. Races differ mainly in darkness of plumage, nominate darkest: *salvini* is close to nominate, male slightly less dark; *insularis* male is palest, brownish-red above, crown patch scarlet, throat, chest and undertail-coverts pale scarlet, breast and belly duller brownish-grey, tinged red; *discolor* male is slightly darker than previous; *willisi* similar to nominate but with more extensive red above and below; *willisi* and *erythrolaema* females are palest, brownish-olive above, olive-yellow below, with yellowish throat and brownish-tinged flanks. Voice. Often quite vocal. Song, mainly at dawn during breeding season, a rich mellow series of whistles, e.g. "cherry-quick cherry-quick cherry-quick cherry-chewer" or similar phrase, repeated over and over. At least three types of call, including a raspy scold of 2–20 notes, a high rattling "scack ack-ack" like static on a radio (or tearing paper) as birds flee from intruders, and soft "wik" and faint "chak".

Habitat. Found in older second growth and forest borders or shrubby areas near forest. Especially fond of thickets at edge of forest, thick growth along streambanks, and shady overgrowth shrubbery in old plantations; much less often in interior of humid forest. Sea-level to c. 1200 m in Mexico, Costa Rica and Panama; to c. 200 m in Colombia.

Food and Feeding. Arthropods, including ants (Formicidae), caterpillars (including some up to three times length of bird's bill), and long-horned grasshoppers (Tettigoniidae). Of five stomachs examined, two contained animal matter, one had vegetable matter, and two had both; contents included beetles (Coleoptera) and other insects, fruit, grass seeds, berries, and a small snake. In pairs when breeding, but at other times in family parties or noisy groups of up to about eight individuals; may associate with small understorey mixed-species flocks for short periods of time, or more often alone. With other species mainly around army-ant swarms, which it follows regularly. Forages in restless, nervous manner, with much wing-flicking and agitated calling as it hops. Of c. 4000 observations of foraging attempts in Belize, 75% were below 5 m; often foraged on ground around army-ant swarms. Around army ants mostly uses horizontal perches, peers rapidly, frequently turns about-face on branch, hops along branches, then lunges for escaping insects or hops on ground briefly to grab prey. Occasionally flutters upwards to beneath leaf, or hovers or sallies for flying insects. Behaviour similar away from ant swarms, where perches mostly in horizontal position and reaches or pecks prey from foliage and trunks. Frequently inspects curled dead leaves or accumulated leaves and debris in branch forks.

Breeding. Season at least Apr–Jun in Costa Rica. Apparently a co-operative breeder at times. Nest built by female, occasionally helped by other dull-plumaged birds, presumably subadults, a bulky, loose structure of leaves and other coarse material, mostly 1–5 m up in shrub or small spiny palm; in Belize, 33 nests were inside forest at heights of 1·4–7 m, mostly in sapling. Clutch 2–4 eggs, mostly 3, white; incubation by female, period 12–14 days; chicks fed by both adults, sometimes also by helpers if present, nestling period c. 9 days; young leave nest well before able to fly. Many nests fail owing to predation or unknown cause.

Movements. Resident.

Status and Conservation. Not globally threatened. Widespread, and locally fairly common. Occurs in various protected areas, including Tikal National Park (Guatemala), Indio-Maíz Biological Reserve (Nicaragua), La Selva Biological Reserve (Costa Rica), La Amistad International Park (Costa Rica and Panama), and Santa Fé, Soberanía and Chagres National Parks (Panama). Present also in unprotected lowland forest sites in Guatemala, Belize, Honduras, Nicaragua and C Panama. In E Mexico, El Salvador, Costa Rica and much of Panama, deforestation is so extensive that the species may survive primarily in protected sites. Despite a checkered distribution of range contraction and fragmentation, the species' viability should be secure so long as protected sites are maintained. Further, it appears able to persist locally in some second-growth and disturbed areas.

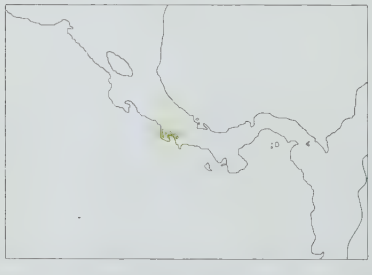
269. **Black-cheeked Ant-tanager**



Habia atrimaxillaris

French: Habia à joues noires **Spanish**: Habia Carinegra
German: Schwarzwangen-Ameisentangare

Taxonomy. *Phoenicothraupis atrimaxillaris* Dwight and Griscom, 1924, Puerto Jimenez, Puntarenas, Costa Rica.

Molecular-genetic evidence indicates that this genus may form a monophyletic group with *Piranga* and *Chlorothraupis*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. Monotypic.

Distribution. Vicinity of Osa Peninsula and Golfo Dulce (S Puntarenas), in SW Costa Rica.

Descriptive notes. 19 cm; one male 48·9 g. Relatively dull ant-tanager, strong-billed and with dark head. Male has partly concealed crown patch salmon-orange, the feathers long but normally held flat (crest rarely obvious); rest of crown dark grey, tinged reddish, forehead, lores and side of head dusky to sooty black, forming rather broad, diffuse mask (does not contrast strongly with back); upperparts dark grey, tinged reddish, tail blackish; upperwing-coverts and flight-feathers blackish, edged dark grey; throat bright pinkish-scarlet to salmon, becoming red-tinged grey on breast and darker grey with pink tinge on belly; iris dark red; bill dusky; legs dark horn. Female is similar to male, but central crown patch smaller and duller, head dull dusky, throat duller salmon, and plumage overall much duller. Juvenile is even duller than female, lacks red, is more brownish to sooty above, no crown patch, side of head and chin dark sooty brown, throat duller and greyish, underparts brownish with faint sooty shaft streaks, flanks dusky; immature male much like female. Voice. During foraging, groups continually give low, nasal "chit" and "chet" notes mixed with rough scolding notes similar to those of *H. fuscicauda* but more abrupt, e.g. "rrak" or "rruk". Song, only at dawn and presumably only during breeding season, usually from at least partial concealment, a clear, sweet whistled "tu-see, tu-see, tu-see" or "tu-seeur tu-swee tu-seeur".

Habitat. Dense lowland forest, streamside woodland, older second growth, occasionally selectively logged forest, palm trees and beach-front scrub; mainly inside mature humid forest. Sea-level to c. 200 m.

Food and Feeding. Arthropods; also some fruits, including berries of melastomes and Solanaceae. Found in pairs and in small groups, often with other birds in small mixed-species flocks. Forages mostly c. 1–6 m up in understorey, where it hops, peers and chases arthropod prey. Gleans small insects from leaves and twigs, rummages in dead-leaf clusters, inspects hanging dead leaves, and occasionally follows swarms of army ants (Formicidae). Squeezes the pulp of fruits.

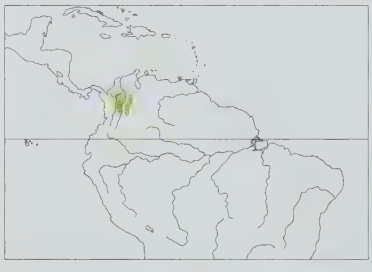
Breeding. Few nests found. Season approximately mid-Jan to May, spanning dry season and early rainy season; nests with eggs in late Jan, nest-building seen Feb–Mar and fledglings seen in May. Nest a bulky cup, outer layer of large dead leaves, vines, twigs and dry grass, middle layer of smaller, thinner dry twigs and vines, lining entirely of black fungal rhizomorphs, internal diameter 65·5 × 71 mm and 64·6 × 70·7 mm, cup depth 20 mm and 31 mm; nest supported by branches and leaf petioles, but not woven or fastened to plant, 0·5–2 m above ground, two nests placed very close to bank of river, two located near top of small shrub, another in top of *Dieffenbachia*, all in tall, older secondary forest. No information on clutch size; eggs immaculate white, slightly transparent when fresh, 26·05 × 18·89 mm and 26·57 × 18·94 mm. No other information. Nest structure and eggs most like those of *H. fuscicauda*.

Movements. Resident.

Status and Conservation. ENDANGERED. Restricted-range species: present in South Central American Pacific Slope EBA. Locally fairly common; declining. Found only on the Osa Peninsula and around the Golfo Dulce, in SW Costa Rica. Its range has been reduced by half since 1960. As recently as 1989 the species was still fairly common in unprotected forest areas in the Osa Peninsula area; since then it has become increasingly scarce and local in fragmented and ever-shrinking forested habitat outside Corcovado National Park and Golfito Faunal Refuge. Population in these protected areas remains stable.

Bibliography. Anon. (2010a), Butchart & Stattersfield (2004), Capper *et al.* (1998), Davis (1972), Garrigues & Dean (2007), Isler & Isler (1999), Roxero-Bixby *et al.* (2002), Sandoval & Gallo (2009), Skutch (1954), Slud (1964), Stattersfield & Capper (2000), Stiles & Skutch (1989), Willis (1972).

270. **Sooty Ant-tanager**



Habia gutturalis

French: Habia fuligineux **German**: Graurücken-Ameisentangare **Spanish**: Habia Sombría

Taxonomy. *Phoenicothraupis gutturalis* P. L. Sclater, 1854, Nova Grenada = Colombia.

Molecular-genetic evidence indicates that this genus may form a monophyletic group with *Piranga* and *Chlorothraupis*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. Monotypic.

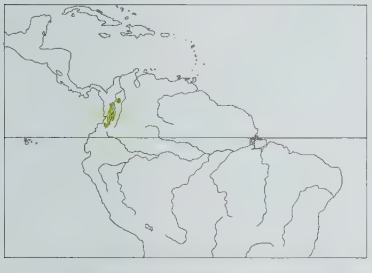
Distribution. NW Colombia along N base of Andes from Córdoba (upper R Sinú) E to Santander, and S on both slopes of Magdalena Valley to N Tolima on W side and to W Santander (SW of Bucaramanga and N of San Vicente), W Boyacá (including Reserva El Paujíl, in Serranía La Quinchas) and N Cundinamarca on E side.

Descriptive notes. 20 cm. Long-tailed ant-tanager with strong bill, male with striking pinkish-and-black plumage. Male has head and upperparts, including upperwing-coverts, flight-feathers and tail, mostly slaty to blackish-grey, with pinkish-scarlet crest conspicuous when raised (often held flat, except when alarmed or excited); side of head and side of throat black, central throat and chest bright rose to pinkish; rest of underparts dark grey; iris brown; bill blackish; legs dark grey. Female is similar to male, but duller, with brownish-tinged plumage, crest much shorter and duller, and throat greyish-white, tinged pink. Juvenile resembles female. Voice. Alarm and territorial-defence calls include fast, chattering, grating "chat-cha-cha-cha-cha-cha..." 5–15 notes at up to 5 notes per second, often ending with one or more static-like "chack" notes; notes sometimes doubled and delivered with distinct syncopated beat, e.g. "cha-chick, cha-chack...". Also "chak" notes when foraging, a "wik", rattles and contact note. Dawn song, usually from perch c. 3–8 m up, perhaps the most musical of those of all the ant-tanagers, somewhat variable, given in deliberate fashion, typically 2–4 rich whistles, the middle ones higher in pitch than the preceding one, then the last somewhat lower, "waa, wuu weet, wu", repeated a few times, then pattern changing slightly or interrupted with harsh scolding notes, then the sequence repeated at faster or slow speed, or with some pairs of notes given more quickly. In longer variation may sound like "cheh, wher, whereyeh, whoa, pong", and "where'errr", then may switch to different series of notes. Songs given near nest when female out of sight, and especially at dawn or dusk as male moves through understorey. Apparently no day song.

Habitat. Understorey of tall second growth, wooded streamsides, bushy forest borders and inside tall humid forest and primary forest in middle Magdalena Valley. Also colonizes dense young second growth in landslides, along streambanks, even regenerating young, dense, low growth in former pastures, and may benefit to some extent from limited forest disturbance by humans. Mainly restricted to foothill forest regions; c. 100–1400 m.

Food and Feeding. Small arthropods; infrequently eats or pecks at fruit. Like others of genus lives in pairs or family groups of 3–4 individuals; sometimes associates with mixed-species flocks, but much more often found away from flocks, where it is often wary and fast-moving and difficult to see. Pairs notably territorial, and hostile encounters at borders involve chattering, wing-flicking and tail-flicking, short flights and raising and spreading of crest. Forages mostly 1–5 m up in understorey, or a little higher (4–10 m) in tall forest. Searches for insects on bare horizontal perches or executes short sallies; regularly follows army ants (Formicidae), when it sallies to foliage above the ants or sallies to ground for arthropod prey.

Breeding. Nine birds in breeding condition in Feb–May in S Bolívar and S Córdoba, and juvenile with two adults in early May in E Antioquia. Nest described as a deep loose cup of roots and fibres, lined with ferns, and located in bush near stream in hills; one was a leafy cup in crown of fishtail palm (*Caryota*) 0·6 m above a creek in tall forest. Clutch probably 2 eggs, white or pale grey marked with reddish-brown and lilac, especially at large end; nestlings fed by both adults. No other information.



Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Nechí Lowlands EBA. Generally rare and local. Occurs in the protected and privately operated Reserva El Paujil (W Boyacá) and in tiny Reserva Bellavista (near La Victoria, in SE Caldas). Present also in scattered patches of unprotected forest and second growth, but much of the unprotected habitat (both primary and regrowth) formerly occupied has now disappeared, and this species has doubtless undergone extensive range contraction and fragmentation. Survives locally in dense and surprisingly young second-growth scrub and palmetto (e.g. N of San Vicente, in Santander), but the long-term viability of this species is of concern as there are few protected sites within its range, and deforestation is widespread, although perhaps slowing. Recent mapping of this species' range, however, suggests that it may be more widespread than was believed.
Bibliography. Álvarez-Rebolledo *et al.* (2007), Anon. (2010a), Butchart & Stattersfield (2004), Donegan & Briceño (2005), Hilty (1985), Hilty & Brown (1986), Isler & Isler (1999), Klicka *et al.* (2007), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Ogilvie-Grant (1912), Quevedo *et al.* (2006), Renjifo *et al.* (2002), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan, Cuervo & Ochoa (2001), Sclater & Salvin (1879), Stattersfield & Capper (2000), Stiles *et al.* (1999), Willis (1972).

271. **Crested Ant-tanager**

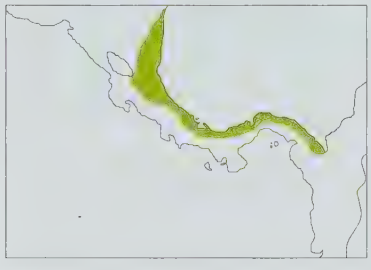
Habia cristata

French: Habia à crête rouge **Spanish**: Habia Copetona
German: Scharlachhauben-Ameisentangare

Taxonomy. *Phoenicothraupis cristata* Lawrence, 1875, "Bogotá", Colombia. Molecular-genetic evidence indicates that this genus may form a monophyletic group with *Piranga* and *Chlorothraupis*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. Monotypic.
Distribution. W Colombia on W slope of W Andes from Antioquia S to S Cauca (Cerro Munchique), locally on E slope of W Andes.

Descriptive notes. 19 cm. Strong-billed ant-tanager with "bicoloured" appearance, red and greyish. Male has long, prominent crest scarlet, most often held erect (occasionally held flat in narrow rearward-pointing spike); rest of crown and side of head dusky, tinged red; mantle red, becoming darker crimson to brownish-red on rump and uppertail-coverts; tail dusky, edged red; upperwing-coverts and flight-feathers dusky, tinged red, tertials more broadly edged and tinged dark red; throat and chest bright scarlet, centre of lower underparts grey, stained red, sides and flanks contrastingly grey; iris reddish-brown; bill blackish; legs dusky grey to dusky pink. Female is similar to male, but crest shorter, and overall slightly duller and with less grey on sides and flanks. Immature is mainly russet-brown above, slightly paler cinnamon-brown below, and lacks crest. Voice. Mobs with loud, shrill "chi-veek!", repeated 2–4 times or over and over in long series; contact calls "chip" or a sharp series of "chee" notes. Dawn song 3–4 unmusical, monotonous "che'ik" notes, repeated up to a dozen times per minute.
Habitat. Understorey of humid pre-montane and montane forest, especially dense or bushy regrowth vegetation along rushing streams, around landslides and in steep ravines; occasionally at openings to woodlots or in isolated trees in pastures. At 700–2000 m.
Food and Feeding. Food mostly insects, caterpillars and other arthropods; also some fruit, and regularly eats *Miconia*, palm seeds and other fruits, but usually only few at any time. Occurs in pairs and in small groups of 2–5 individuals (probably family parties). Moves rapidly through undergrowth, foraging mostly 1–10 m up, higher than congeners, and frequently with mixed-species flocks or at feeding associations in small fruiting trees. Typically rather wary, but can at times be inquisitive and may perch partly in open briefly to peer and scold at intruders. Foraging territory c. 5–8 ha, and boundaries disputed by males, which posture with raised and spread crest, fluffed body feathers and spread tail, facing alternately towards and away from each other while nearby families intermingle. Searches by perching on horizontal bare branches and peering at foliage, often methodically, before moving. Like others of genus, reaches out to twigs and leaves for prey, or flutters or hovers briefly, and may sally to snap prey from substrates or to catch falling prey. Also takes arthropods from hanging dead leaves. Up to ten have been observed together at an army-ant (Formicidae) swarm.
Breeding. One bird, accompanied by two others, seen carrying nesting material in deep streamside ravine in N Tolima, in Jun. No other information available.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Chocó EBA. Fairly common locally. Can be found in a few parks and preserves, including Farallones de Cali National Park, Otún-Quimbaya Sanctuary, Tambito Nature Reserve, and probably Munchique National Park. Also occurs locally in unprotected watersheds, e.g. on E slope of W Andes above Cali (Pichindé), E slope of C Andes in Tolima (areas near Ibagué; above Líbano, etc.) and at N end of C Andes in Antioquia and Caldas. This species' numbers are undoubtedly declining; it has experienced considerable range contraction and fragmentation because of deforestation, and should probably be regarded as being at risk in the near future.
Bibliography. Álvarez-Rebolledo *et al.* (2007), Donegan & Dávalos (1999), Gochfeld & Tudor (1978), Hilty (1985, 2009b), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Willis (1966b).

Genus *CHLOROTHRAUPIS*



Salvin & Godman, 1883

272. **Carmiol's Tanager**

Chlorothraupis carmioli

French: Habia de Carmiol **German**: Carmioltangare **Spanish**: Tangara de Carmiol

Taxonomy. *Phoenicothraupis carmioli* Lawrence, 1868, Angostura, Costa Rica.
Molecular-genetic evidence indicates that this genus may form a monophyletic group with *Piranga* and *Habia*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. This species often treated as conspecific with *C. frenata*, the two being morphologically very similar; further investigation desirable. Three subspecies provisionally recognized.
Subspecies and Distribution.
C. c. carmioli (Lawrence, 1868) – Caribbean slope and lowlands and very locally on Pacific slope at low passes from E Nicaragua S to extreme NW Panama (vicinity of Almirante Bay).
C. c. magnirostris Griscom, 1927 – W Panama (both slopes in Veraguas).
C. c. lutescens Griscom, 1927 – from C Panama (Coclé and Colon locally E to San Blas and NW Darién, generally N & E of valleys of R Chepo and R Chucunaque, and on Cerro Tacarcuna) and adjacent extreme NW Colombia (slopes of Cerro Tacarcuna, in Chocó).

Descriptive notes. 16 cm; 30·5–44 g. Robust tanager with heavy bill and nearly uniform plumage. Nominate race has head and entire upperparts, including upperwing-coverts and tail, intense olive, lores and ocular area slightly darker than rest of head; flight-feathers dusky, edged yellowish-green; throat and underparts yellowish-green, slightly paler than upperparts, flanks greenish-olive, underwing-coverts greenish-yellow; iris light to dark brown; bill blackish, variably paler grey on most of lower mandible; legs dark grey. Sexes similar. Juvenile is similar to adult, but iris dull grey. Races differ mainly in measurements and in plumage tone, nominate more greenish (less yellow) than others: *magnirostris* is very similar to nominate, but bill longer and heavier, and chin and throat lighter, more yellowish (less olive); *lutescens* is very like nominate, but slightly more yellowish on throat and underparts, and with less olive tinge in plumage. Voice. Dawn song a rapid stream of mostly short notes, some grating or wheezy, some musical, and typically given rapidly in groups of 3–8, then abruptly switching to another type of note, entire sequence often lasting up to several minutes; some song sequences consist of clear whistled notes much like those of Northern Cardinal (*Cardinalis cardinalis*). Can be rather noisy when foraging, uttering variety of mostly short, high, thin notes, including "chay", a squeaky "eep", a churring "wrsst", and abrupt "chut", squeezed "chee" and metallic "whit"; also a slightly buzzy "seeet" or "seee-seeee" and staccato "tik" in bursts when about to fly; in alarm a scratchy "nyaaah" or "cheeyah".
Habitat. Undergrowth of humid and wet lowland and foothill forest and adjacent tall second-growth woodland, less often along forest borders; in Panama reported as favouring vicinity of wetter areas near rivers. In Panama mostly c. 300 m to 1000 m, locally to 1450 m.
Food and Feeding. Arthropods, including beetles (Coleoptera), cockroaches (Blattodea), crickets (Gryllidae), katydids (Tettigoniidae); also some berries and fruit. In Panama seen to eat arillate fruits of *Lindackeria*; in Costa Rica reported as eating many berries, especially of melastomes, and taking pieces from large *Coussarea* (Rubiaceae). Usually encountered in rather noisy, single-species flocks of 5–15 individuals, also in pairs when breeding. Groups may follow regular routes and defend a common flock territory, and sometimes join or are joined by other species of flocking birds, especially *Tachyphonus delatrii*. Forages mostly c. 2–6 m up in understorey, occasionally higher, where it hops rather heavily in vegetation, rummaging and peering for arthropods, lunging forward or hanging downward for fast or fleeing prey. From a sample of 59 insect-searching records, 63% were on foliage, and 65% of these were from underside of leaves.
Breeding. Breeding reported in Apr in Nicaragua, Mar–May in Costa Rica and Mar in Panama. Nest a neat cup of mosses and long plant fibres, with some leaves at base, lined with fine rootlets and black fungal rhizomorphs, placed 1·5–2·5 m up in fork of understorey shrub or tree. Clutch 2 eggs, creamy white, speckled brown and lavender, especially around larger end. No other information.
Movements. Resident.
Status and Conservation. Not assessed. Believed not globally threatened. Fairly common to common, especially in humid and wet hilly terrain and foothills. Occurs in several protected areas, including Indio-Maíz Biological Reserve (Nicaragua), La Selva Biological Reserve and Braulio Carrillo National Park (Costa Rica), and Soberanía and Darién National Parks and Comarca Kuna Yala Indigenous Reserve and Atlantic Forest (Panama). The species occurs primarily inside primary forest and tall, older second growth, making it sensitive to human disturbance. Much hill-country forest within its range has been lost to deforestation as human settlement and agriculture increase. Most unprotected habitat within its range has now disappeared, creating range contractions and distributional gaps. Populations now fragmented and declining, but the long-term viability of this species will likely continue so long as there is adequate protection of existing parks and reserves.
Bibliography. Burns (1997a), Burns *et al.* (2002, 2003), Davis (1972), Garrigues & Dean (2007), Greenberg (1981a, 1984), Greenberg & Gradwohl (1980), Huber (1932), Isler & Isler (1999), Klicka *et al.* (2007), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Ross & Whitney (1995), Salaman *et al.* (2008), Slud (1960, 1964), Stiles & Skutch (1989), Wetmore *et al.* (1984).

273. **Olive Tanager**

Chlorothraupis frenata

French: Habia bridé **German**: Streifenkehltangare **Spanish**: Tangara Embridada
Other common names: Yellow-lored Tanager

Taxonomy. *Chlorothraupis frenata* Berlepsch, 1907, Marcapata, Peru.
Molecular-genetic evidence indicates that this genus may form a monophyletic group with *Piranga* and *Habia*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. This species often treated as conspecific with *C. carmioli*, the two being morphologically very similar; further investigation desirable. Monotypic.
Distribution. S Colombia at E base of Andes (Caquetá and Nariño), Ecuador (along E base of Andes N of Lumbaquí, in Sucumbíos; Loja–Zamora Road in extreme SE), and E base of Andes in Peru (C Huánuco S to C Pasco, and from C Cuzco) S to WC Bolivia (Cochabamba).
Descriptive notes. 16 cm. Robust, heavy-billed tanager with nearly uniform plumage (especially male). Male is almost entirely dingy olive-green above, slightly paler below; lores and, especially, throat somewhat yellowish, vaguely olive-streaked; iris light to dark brown; bill blackish, variably paler grey on most of lower mandible; legs dark grey. Differs from very similar *C. carmioli* in having lores and facial area paler, more yellowish. Female is very similar to male (and to either sex of *C. carmioli*), but loral area and face distinctively yellowish (not olive) and throat lighter, more clear yellow, and without streaking. Juvenile undescribed. Voice. Song in SE Peru an excited, rapid

rolling "ki'r'r'rup-ki'r'r'rup-ki'r'r'rup-ki'r'r'rup-ki'r'r'rup...", sometimes up to c. 8 notes in the series with squealing, frantic quality, and often repeated over and over at short intervals. At times song more varied, with other high or squeaky notes inserted into the long series, e.g. "ki'r'r'rup-ki'r'r'rup-ki'r'r'rup-éé-kir'r'r'r-éé-kir'r'r'r, squik-Skeek-Skeek-Skeek-kir'r'r-kir'r'r..." and so on for up to 30 seconds or more; also transcribed as a grating "kettup" or "keetup". A somewhat more melodic song (context uncertain) is a series of several similar notes, then a series of different notes, and so on, e.g. "chow-chow-chow-chow-chi-chi-chi-chow, chow, chow, whi-chow, whi-chow, wheeup, wheeup, wheeup, wheeup, tic-chow tic-chow, tic-chow, tic-chow, tic-chow, tic-tic-tic-tic-ch-ch-ch-ch...", for 10–25 seconds. Songs and other vocalizations rather unlike those of *C. carmioli*.

Habitat. Humid foothill and pre-montane forest along E base of Andes and also, at least in Peru, on outlying ridges. At c. 300–1000 m; to c. 800 m in Colombia, c. 600–1100 m in Ecuador and 400–1350 m in Peru.

Food and Feeding. Arthropods, also fruit; has been seen to eat *Cecropia* catkins. Of 13 stomachs examined, two contained only vegetable matter, nine only animal matter and two both; contents included fruit, seeds, beetles (Coleoptera) and other insects. Occurs singly and in pairs, sometimes in small groups of 3–4 individuals that join, or are joined by, other small understorey passerines. Stays mainly in undergrowth c. 1–6 m up, occasionally higher, and can be difficult to see. Foraging movements and behaviour reminiscent of those of larger members of genus, but seems more restless and faster-moving, often constantly flicking wings and tail in agitated manner as it hops along branches and in tangles and foliage or flies short distances through understorey.

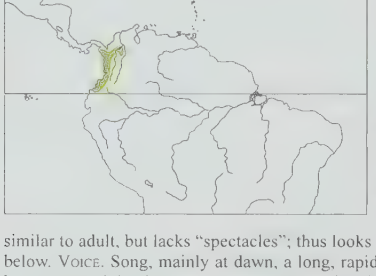
Breeding. No information.

Movements. No information; almost certainly resident.

Status and Conservation. Not assessed. Believed not globally threatened. Locally fairly common; distribution in Colombia and Ecuador particularly spotty and poorly known. Has recently been reported as numerous in the Bermejo oil-field area N of Lumbaquí (Sucumbíos), in N Ecuador. Found in a narrow elevational band along E base of Andes that is subject to extensive deforestation and human settlement. Occurs in a few protected areas, most notably the Manu Biosphere Reserve (SE Peru) and Madidi National Park (Bolivia). Deforestation in unprotected areas is extensive, especially in Colombia and locally in Ecuador, and has almost surely contributed to range contractions and distributional gaps. Despite local population declines, the species' long-term viability seems secure so long as existing protected areas are maintained.

Bibliography. Hilty (2009a, 2009b), Hilty & Brown (1986), Isler & Isler (1999), Mee *et al.* (2002), Meyer de Schauensee (1966, 1970a), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (1999), Schulenberg (2000a), Schulenberg *et al.* (2007), Zimmer (1947a).

274. Lemon-spectacled Tanager



Chlorothraupis olivacea

French: Habia à lunettes **German**: Gelbbrauentangare **Spanish**: Tangara Olivácea
Other common names: Lemon-browed Tanager, Spectacled Tanager

Taxonomy. *Orthogonys olivaceus* Cassin, 1860, River Truandó, north-west Colombia.

Molecular-genetic evidence indicates that this genus may form a monophyletic group with *Piranga* and *Habia*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. Monotypic.

Distribution. Pacific slope in extreme E Panama (SE Darién S & E of R Chepo and R Chucunaque) and W Colombia (E along N base of Andes to Magdalena Valley in Antioquia, and in Pacific lowlands) S to NW Ecuador (N Esmeraldas).

Descriptive notes. 17 cm; 36–41 g. Robust species with conspicuous "spectacles" and strong, heavy bill, but dingy plumage. Male is uniformly dark olive above, including head, upperwing and tail; lores and prominent, contrasting eyering bright yellow; chin and throat dull yellow, vaguely streaked along lower border; underparts dark olive, becoming yellowish on belly and undertail-coverts; iris reddish-brown; upper mandible blackish with pale line along cutting edge, lower mandible light blue-grey; legs grey. Female is essentially similar to male, but slightly paler and more yellowish on lower underparts. Juvenile is similar to adult, but lacks "spectacles"; thus looks much like *C. stolzmanni*, but not so ochraceous below. Voice. Song, mainly at dawn, a long, rapid series of notes that begins softly, then rapidly becomes much louder, e.g. "wu-wu-wu-wu-chu-chu-chu-chéé-chéé-chéé-chéé". Often noisy when foraging, uttering rapid, excited "treu-treu-treu-treu..." of 4–8 notes; also "turee" and "jee-ut", and "eep", and other notes and more nasal "nyaah-nyaah-nyaah-nyaah-nyaah".

Habitat. Lower levels of wet lowland and foothill forest and adjacent second growth, especially along streams. Sea-level to c. 400 m in Ecuador; to 1500 m (although rarely above c. 400 m) in Colombia.

Food and Feeding. Two stomachs contained animal matter, another had both animal and plant material; contents included parts of ants (Formicidae), coleopterans including weevils (Curculionidae) and scarab beetles (Scarabaeidae), caterpillars, wasps (Vespidae), and seeds of *Solanum*. Occurs in pairs and in small groups of three or four individuals, often joining or joined by mixed-species flocks. Groups stay mainly in undergrowth, mostly out of sight, and, except for chattering calls, are easily overlooked.

Breeding. No information.

Movements. Resident.

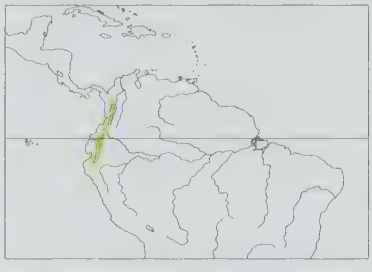
Status and Conservation. Not globally threatened. Uncommon to locally fairly common in Colombia; decidedly less numerous at S end of range in extreme NW Ecuador. Occurs in a few protected areas, including Darién National Park (Panama) and Los Katíos, Ensenada de Utría and possibly Sanquianga National Parks (Colombia), but most of range lies outside protected areas. Extensive and ongoing deforestation in much of its range is a longer-term risk, and habitat loss is fragmenting its range, resulting in overall decline in numbers. On the positive side, the species utilizes a variety of shrubby forest-edge and second-growth habitats and does not appear to be at any immediate risk in Colombia. Relatively little suitable habitat remains within its range in W Ecuador.

Bibliography. Burton (1975), Chapman (1917, 1926), Davis (1972), Dunning (1982), Haffer (1975), Hilty & Brown (1986), Isler & Isler (1999), Jahn *et al.* (2002), Klicka *et al.* (2007), Meyer de Schauensee (1964, 1966, 1970a), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008).

275. Ochre-breasted Tanager

Chlorothraupis stolzmanni

French: Habia de Stolzmann **German**: Ockerbrusttangare **Spanish**: Tangara Pechiocre



Taxonomy. *Phoenicothraupis stolzmanni* Berlepsch and Taczanowski, 1884, Chimbo, Ecuador.

Molecular-genetic evidence indicates that this genus may form a monophyletic group with *Piranga* and *Habia*, and that all three are more closely related to cardinals (Cardinalidae) than to true tanagers. Races weakly differentiated. Two subspecies recognized.

Subspecies and Distribution.

C. s. dugandi Meyer de Schauensee, 1948 – Pacific slope of Andes in Colombia (Risaralda S to Nariño); extreme NW Ecuador (El Placer, in Esmeraldas).

C. s. stolzmanni (Berlepsch & Taczanowski, 1884) – W slope of Andes in Ecuador from Pichincha S to El Oro.

Descriptive notes. 17 cm; 36·6–43 g. Large and robust, with stout bill and few obvious field marks. Nominate race has head and upperparts, including upperwing and tail, dull dark olive-green with brownish tinge; throat and centre of lower underparts dull ochraceous, rest of underparts dull clay-coloured, breast, sides and flanks tinged olive; iris brownish-grey; bill dusky, basal portion of lower mandible pale blue-grey, sometimes pinkish at corner of gape; legs dusky horn. Sexes similar. Juvenile is darker than adult, dingy brownish, with no pattern or contrasts in plumage. Race *dugandi* is very like nominate, but has greyish tone on crown and is slightly paler below. Voice. Rather vocal, like many congeners. Dawn song, given all year, from high exposed canopy perch, a fast, energetic series of variable and mostly unmusical phrases, e.g. "geegeegee wit'er wit'er tututu, weep, twéér- twéér-twéér, eep'eep k'eep eep eep twéér- twéér-twéér jeep-jeep twéér..." and so on in loud uninterrupted stream for half an hour or more; thin "eep" notes extremely high-pitched. Each individual has distinctive repertoire. When foraging, chatters incessantly with rough "jeep-jeep-jeep-jeep"; mobs with loud "jee'ut" and other notes.

Habitat. Mostly in lower storey of wet foothill and pre-montane forest and along adjacent borders; recorded at 200–2100 m in Colombia, and mostly 400–1500 m in Ecuador. Confined mostly to a rather narrow elevational band along W base of Andes, corresponding closely to belt of highest rainfall in Western Hemisphere.

Food and Feeding. Fruits and insects, also flowers. Of 232 feeding records in study in upper R Anchicayá watershed (W Valle del Cauca), in Colombia, fruit-eating comprised 71% of observations, insect-hunting c. 27% and searching at flowers c. 2%. Recorded as eating at least 24 species of fruit, primarily melastomes (87% of all fruit-eating observations), of which 57% were of genus *Miconia*. Frequently captured large insects, including katydids (Tettigoniidae), skippers (Hesperioidea) and moths (Lepidoptera). Forages in groups of 5–15 individuals throughout year; often joined by other small passerines. In upper R Anchicayá watershed, foraged in a rather plodding manner with heavy hopping in understorey vegetation. Most observed foraging was 1·5–9 m up, more rarely ascended to 15 m or higher, and generally foraged lower for insects than for fruit; median foraging height c. 5·5 m. Perched or occasionally hung downwards awkwardly to take fruit, and snatched berries in short sallies or lunges. Searched for insects by hopping on small live or dead and bare or mossy branches (less than 2·5 cm in diameter) and peering. Used wide range of foraging motions, many of them involving rather clumsy acrobatics, including hanging downwards, stretching upwards, reaching around or under leaves and branches, lunging, and diving to pursue fleeing or perched prey, but seldom took prey in the air.

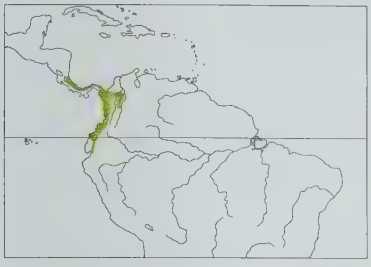
Breeding. In Colombia (R Anchicayá), four nests found mid-Jan to mid-Feb, stub-tailed fledgling early Apr, and one female with brood patch in mid-Jun. Rough cup-nest placed 2–5 m up in fork of sapling inside forest; clutch 1–2 eggs, white with dense ring of reddish-brown spots, mostly at large end. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Fairly common to common locally in Colombia and extreme NW Ecuador (El Placer); decidedly less numerous and more local S in W Ecuador. Occurs in only a few protected sites, including Farallones de Cali National Park (Colombia) and Cotocachi-Cayapas Ecological Reserve and Reserva de Milpe (Ecuador). Deforestation within this species' range, especially in Ecuador, is extensive and its habitat is fragmented. Viability of this species, however, at least in short term, is probably secure so long as existing protected areas are maintained.

Bibliography. Donegan & Dávalos (1999), Hilty (1997, 2009b), Hilty & Brown (1986), Isler & Isler (1999), Klicka *et al.* (2007), Lysinger *et al.* (2005), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Moore *et al.* (1999), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008).

PLATE 33 ➤



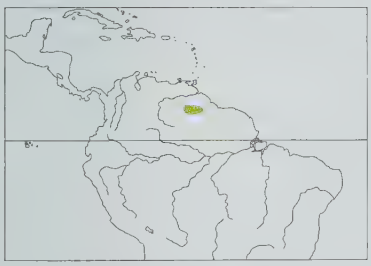
Genus *MITROSPINGUS* Ridgway, 1898

276. **Dusky-faced Tanager**

Mitrospingus cassinii

French: Mitrospin obscur **German**: Rußgesichttangare **Spanish**: Tangara Carinegruzca

Taxonomy. *Tachyphonus Cassinii* Lawrence, 1861, Lion Hill, Panama.
Recent molecular-genetic data indicate that this genus may be unrelated (or, at least, not closely related) to any other in present family; affiliations uncertain, and no closely related family or sister-taxon yet identified. Two subspecies recognized.
Subspecies and Distribution.
M. c. costaricensis Todd, 1922 – Caribbean lowlands of Costa Rica (from Heredia) S to extreme NW Panama (vicinity of Almirante Bay).
M. c. cassinii (Lawrence, 1861) – Caribbean lowlands of W Panama (from Veraguas and Chiriquí Lagoon E to E Darién, also locally on Pacific slope in Veraguas); and Colombia at N end of W Andes (R Nechí) E to Serranía de San Lucas, S on E slope of C range in Caldas (to Tasajos; La Victoria), and entire Pacific lowlands (from Chocó) S to W Ecuador (S to Guayas).
Descriptive notes. 18 cm; 32–41 g. Relatively dull species with rather long, slender and conical bill, and feathers of face rather short and stiff. Nominate race has centre of crown mustard-yellow; forehead, lores, entire side of head, including area above eye, black, forming large dark mask, shading to dark grey on throat; rear and lower half of ear-coverts slightly paler; upperparts, including upperwing and tail, plumbeous grey, uppertail-coverts faintly tinged olive; chin narrowly blackish, throat light grey, becoming olive-yellow on breast and sides and flanks, with belly and undertail-coverts dusky grey mixed olive-yellow; underwing-coverts grey; iris pale grey to greyish-white; upper mandible blackish with blue-grey at base, lower mandible blue-grey; legs dark grey. Sexes similar. Juvenile is duller than adult, with mustard-yellow on crown only faintly indicated, underparts tinged buff. Race *costaricensis* differs from nominate in having upperparts slightly darker, more blackish, tinged dark olive, throat slightly darker, and undertail-coverts duller and tinged rufescent. Voice. Song, repeated persistently at dawn, a sharp, high-pitched, emphatic "zeep zeep zeep zeep-it zeepity zeep", described also as "seety, seety, seety, seety, seety". Foraging groups



noisy, uttering incessant clattering, low, gravelly "chet" and "chet-ut" with chattering and metallic quality; other short notes include a high "wss" or "sszeet?" and thin "zeet".
Habitat. Thickets and dense shrubbery along forest borders, light gaps, second growth of various ages, and especially along bushy stream borders and watercourses. Sea-level to 600 m in Costa Rica, up to 1200 m in Panama, and to 1100 m in Colombia and 800 m in Ecuador. In all areas most numerous in lowland and foothill areas, and local at highest elevations.
Food and Feeding. Small arthropods and fruits. In Costa Rica recorded as eating fruits especially of melastomes, Rubiaceae and Solanaceae, also grass seeds (*Lasiacis*) and hard seeds of arillate fruits of *Alchornea*; arthropods taken in W Colombia include orthopterans and spiders (Araneae). Four stomachs contained fruit, including *Carludovica palmate* (Cyclanthaceae); stomach contents of two birds in Panama (at Cana), contained both insects and small fruits, one with c. 15% (by weight) insect parts, and the other c. 65% (by weight) insect parts and much of remainder seeds of various fruits. Nestling diet arthropods, including spiders, grasshoppers (Caelifera), caterpillars. A social species that lives in family groups or single-species groups of up to c. 15 individuals; seldom follows or is joined by other birds. Noisy, excitable groups forage mostly rather low in shrubbery, move rapidly with much agitated wing-flicking and tail-flicking and chattering; generally rather wary and keep out of sight, but may ascend higher to visit fruiting trees and occasionally perch up briefly in semi-open tree or tall bush. In W Colombia took berries from perched position, and hopped along branches and on large leaves to search for prey. Picked insects mostly off foliage, especially from large leaves of *Heliconia* and palm fronds. Sometimes hung upside down from leaves, inspected palm fronds with head down between leaflets, and probed curled arboreal dead leaves. Has been found near ant (Formicidae) swarms.
Breeding. Breeding reported in Mar–Apr in Costa Rica; in Colombia, twelve birds in breeding condition in Feb–May in NW and a stub-tailed juvenile with two adults seen in Sept in W (Anchicayá Valley). Co-operative breeding recorded in Costa Rica, where one nest with two nestlings was attended by at least three and possibly all seven adults in flock. Nest can be thin or bulky, composed of thread-like flower stems and black fungal filaments, placed 1·5–3 m up and slung between two to several upright stems of small tree near stream. Clutch 1–2 eggs, white and spotted with brown and reddish-brown, heavily at large end. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to locally common throughout most of range. Occurs in a number of protected areas, including, among others, La Selva and Braulio Carrillo National Parks and Hitoy Cerere Biological Reserve (Costa Rica), La Amistad, Soberanía, Chagres and Darién National Parks and Pipeline road near L Gatun (Panama), and Los Katíos, Ensenada de Utría and Farallones de Cali National Parks and Tambito Nature Reserve (Colombia). Utilizes bushy second growth, but extensive conversion of lowland areas for cattle grazing, banana plantations and other activities is fragmenting its once continuous range. Nevertheless, appears not to be facing any serious near-term threats.
Bibliography. Burns (1997a), Burns *et al.* (2002, 2003), Burton (1975), Carriker (1910), Davis (1972), Donegan & Dávalos (1999), Garrigues & Dean (2007), Haffer (1975), Hilty (1997), Hilty & Brown (1986), Isler & Isler (1999), Jahn *et al.* (2002), Klicka *et al.* (2007), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Skutch (1972, 1980a), Slud (1960, 1964), Stiles & Skutch (1989), Stiles *et al.* (1999), Wetmore *et al.* (1984), Yuri & Mindell (2002).

277. **Olive-backed Tanager**

Mitrospingus oleagineus

French: Mitrospin à dos olive **German**: Olivmanteltangare **Spanish**: Tangara Dorsioliva

Taxonomy. *Eucometis oleaginea* Salvin, 1886, Mount Twek-quay, Guyana.
Recent molecular-genetic data indicate that this genus may be unrelated (or, at least, not closely related) to any other in present family; affiliations uncertain, and no closely related family or sister-taxon yet identified. Races very weakly differentiated; species may be better treated as monotypic. Two subspecies provisionally recognized.
Subspecies and Distribution.
M. o. obscuripectus J. T. Zimmer & Phelps, Sr, 1945 – Sierra de Lema and cerros of the Gran Sabana (except Roraima area), in SE Bolívar region of SE Venezuela, S to N Brazil (on Uei-tepui).
M. o. oleagineus (Salvin, 1886) – extreme SE Venezuela (vicinity of Mt Roraima) and adjacent Guyana (on Mt Twek-quay); probably also tepui slopes in adjacent Brazil.

Descriptive notes. 19 cm; 35·5–46 g. Rather large, drab and undistinguished in appearance; wings fairly short and rounded, tail longish and rounded, and bill relatively slender. Nominate race has forehead and side of head dark grey, throat and foreneck slightly paler grey, rest of head and mantle to uppertail-coverts deep olive; upperwing-coverts, secondaries and tertials dusky olive (slightly darker than back), primaries and tail mainly dusky; breast and lower underparts olive-yellow, brighter and yellower on belly; iris grey; upper mandible dusky, lower mandible pale blue-grey; legs dark grey. Sexes similar. Juvenile is much duller and plainer than adult, with no grey mask, and iris brownish-grey. Race *obscuripectus* is very similar to nominate, but marginally darker and more olive above. Voice. Easily overlooked song a short "zweee-eet?" or "zwee-er-eet?", often repeated over and over at intervals of 1–3 seconds. Two or three individuals may sing at same time. Calls frequently when foraging, but vocalizations thin, weak, high-pitched and audible only at fairly close range (hence species seems rather quiet), include a very high, thin "seeep", a thin, drawn-out and rising "seeeeeek", a buzzy "pzzzzz, pzzzzz...", also thin ticking "tic'tic'tic" contact notes.
Habitat. Humid and wet forest and forest borders on slopes of tepuis. On Sierra de Lema found in mature forest and in dense, stunted, melastome-dominated second growth on white sandy soil. Much more often inside shady forest (mature or older second growth) than at borders. At 900–1800 m.
Food and Feeding. Mostly insects; also some fruit, especially melastome berries. Moves about in single-species groups of 5–20 individuals, occasionally more; often follows mixed-species flocks, or joined by other species. Appears to be a keystone species in formation and maintenance of some understorey flocks in tepui mountains. Rather sluggish, typically foraging quietly through understorey or lower middle storey of forest, occasionally to c. 15 m up. Searches methodically, mostly by hopping, then peering at foliage, reaching up to snap insect prey, or occasionally lunging in heavy, semi-acrobatic manner to grasp mostly insect prey. Also snatches items from foliage during short clumsy sallies. Reported as searching twigs, bark, moss and dead leaves.
Breeding. No information.
Movements. Resident. Possibly some altitudinal movement to lower elevations during rainiest months; verification required.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tepuis EBA. Fairly common to locally common. Canaima National Park, in Venezuela, protects a large proportion of the range of this species, although the park itself is poorly protected and has remained intact largely because of an extremely low human population in the area. Unlikely to face near-term threats as most of its range is centred on forested lower slopes of tepuis, which are subject to relatively little human impact except for sporadic and localized diamond-mining and gold-mining.
Bibliography. Ascanio (2009), Braun *et al.* (2000), Hilty (2003), Isler & Isler (1999), Klicka *et al.* (2007), Meyer de Schauensee (1966, 1970a), Meyer de Schauensee & Phelps (1978), Phelps & Phelps (1950, 1963), Snyder (1966), Souza (2002), Yuri & Mindell (2002).

Genus *PHAENICOPHILUS* Strickland, 1851

278. **Black-crowned Palm-tanager**

Phaenicophilus palmarum

French: Katje à couronne noire **Spanish**: Cuatro-ojos Coroninegro
German: Schwarzscheitel-Palmtangare
Other common names: Hispaniolan Palm-tanager (when treated as conspecific with *P. poliocephalus*)

Taxonomy. *Turdus palmarum* Linnaeus, 1766, Cayenne; error = Santo Domingo, Dominican Republic.
Recent molecular-genetic studies suggest that this genus and *Nesospingus*, *Chlorospingus* and *Spindalis* form a monophyletic clade that is sister to several New World warbler (Parulidae) genera (including *Dendroica*, *Basileuterus* and *Vermivora*), and are not closely related to other genera of present family. This species forms a superspecies with *P. poliocephalus*; sometimes treated as conspecific, and hybridization between them occurs. Monotypic.
Distribution. Haiti (E from Morne d'Enfer, on W edge of Massif de la Selle) and Dominican Republic (including Saona I).

Descriptive notes. 17–18 cm; 24–32 g. Bill rather long, strong and sharply pointed. Has crown and side of head black, small white supraloral spot, larger trapezoidal-shaped white patch above eye that projects rearwards a short distance, and small inverted white arc below eye; nape grey; upperparts, including upperwing-coverts, bright yellowish-olive; flight-feathers dusky, edged yellowish-olive, tertials and tail yellowish-olive; throat white, white extending narrowly down central underparts and blending gradually into light neutral grey of side of breast, flanks, belly and undertail-coverts; grey on side of chest extends up to meet grey of nape; iris dark red-brown; upper mandible black, lower mandible blue-grey with variable black tip; legs horn-grey. Sexes similar. Immature has black areas replaced by dusky grey, and whitish areas of foreparts tinged buff. Voice. Song varies among populations, but typically consists of jumbled squeaky notes that grow louder, then diminish and slow to short "chit" notes at end; in some areas, song contains more raspy and buzzy phrases. Vocal when foraging, frequently giving nasal, buzzy "pe-u", and higher, more penetrating "tseep", often doubled; also a low "chep".
Habitat. Thrives in variety of habitats; found in dry to humid zones in both urban and rural situations, especially in thickets, gardens, isolated trees, woodland and forest of all types, including mangroves, pines (*Pinus*), even cloudforest. Common in lowlands, less so in highlands. Sea-level to c. 1800 m.
Food and Feeding. Arthropods, also fruits; reported as eating nectar. Takes wide variety of fruits, including species in Rosaceae, Ulmaceae (probably *Celtis trinervia*), Solanaceae, Lauraceae, and Papaveraceae (*Bocconia*). Of five stomachs examined, three contained only vegetable matter and two contained vegetable and animal matter, and included fruit seeds, a large tree-cricket (Gryllidae), a small katydid (Tettigoniidae), a March fly (Bibionidae), leaf-footed bug (Coreidae) and a wasp (Vespidae). From sample of 739 observations, insect-searching comprises c. 68% of feeding records, fruit-eating 30%, and visits to flowers 2%. Occurs in pairs, post-breeding pairs often accompanied by one or more immatures moving in family groups, and sometimes associate with mixed-species flocks in wooded areas. Forages at almost all levels, from ground to treetop, often for extended period of time in one area before moving. Moves in rather deliberate fashion, often flicking tail. Searches for insects mostly on leaves, but c. 12% of attempts were on bark, where it clambers over trunks and large limbs, using strong feet to cling to rough bark, examining twigs and bark, pecking and pulling at loose bark and Spanish moss (*Usnea*), and flying out in short sallies to capture insects.

On following pages: 279. Grey-crowned Palm-tanager (*Phaenicophilus poliocephalus*); 280. Eastern Chat-tanager (*Calyptophilus frugivorus*); 281. Western Chat-tanager (*Calyptophilus tertius*); 282. Rosy Thrush-tanager (*Rhodinocichla rosea*).

Breeding. Breeding reported in Apr in Haiti and May–Jun in Dominican Republic. Deep cup-shaped, loosely formed nest, unlined, placed 1–2 m up (probably also higher) in bush or tree, often near human habitation. Clutch 2–3 eggs, greenish to whitish, spotted, and variable in size; incubation period c. 10 days; nestling period c. 10 days.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Hispaniola EBA. Common. Has successfully adapted to human-altered environments. Occurs in most, if not all, of the 16 national parks, nine natural monuments and six scientific reserves, as well as most other protected areas and ecological corridors, in Dominican Republic, where common throughout also in unprotected rural and urban areas. Common in heavily damaged habitats in Haiti, although rarely found W of Port-au-Prince. There seems to be little near-term risk associated with this species.
Bibliography. Bond (1928a, 1934, 1943, 1948, 1961), Burns (1997a), Burns *et al.* (2002, 2003), Cherrie (1896), Danforth (1929), Dod (1978), Isler & Isler (1999), Keith *et al.* (2003), Latta (2005), Latta *et al.* (2006), Maurrasse & Rigaud (1982), McCarthy (2006), McDonald (1988), McDonald & Smith (1990, 1994), Raffaele *et al.* (1998), Reynard (1981), Rimmer *et al.* (2005), Steadman *et al.* (1980), Townsend (2007), Wetmore (1932), Wetmore & Swales (1931).

279. **Grey-crowned Palm-tanager**

Phaenicophilus poliocephalus

French: Katje à couronne grise **Spanish**: Cuatro-ojos Coronigris
German: Grauscheitel-Palmtangare
Other common names: Hispaniolan Palm-tanager (when treated as conspecific with *P. palmarum*)

Taxonomy. *Dulus poliocephalus* Bonaparte, 1851, Haiti.
Recent molecular-genetic studies suggest that this genus and *Nesospingus*, *Chlorospingus* and *Spindalis* form a monophyletic clade that is sister to several New World warbler (Parulidae) genera (including *Dendroica*, *Basileuterus* and *Vermivora*), and are not closely related to other genera of present family. This species forms a superspecies with *P. palmarum*; sometimes treated as conspecific, and hybridization between them occurs. Three subspecies recognized.
Subspecies and Distribution.
P. p. coryi Richmond & Swales, 1924 – Gonâve I (off WC Hispaniola).
P. p. poliocephalus (Bonaparte, 1851) – S peninsula of Haiti and immediately adjacent SW Dominican Republic; also island of Grande Cayemite.
P. p. tetraopes Wetmore & Lincoln, 1932 – I à Vache (off SW Hispaniola).

Descriptive notes. 17–18 cm; mean c. 31 g. Bill rather long, strong and sharply pointed. Has black forecrown, ocular area and ear-coverts forming large black mask, this highlighted by prominent white supraloral spot, a second white spot over eye and a small inverted arc of white immediately beneath eye (the three spots imparting a "broken-spectacled" appearance); black mask contrasts sharply with grey middle and rear crown, and conspicuous white chin and upper throat, which extends rearwards to submoustachial area and side of neck; upperparts, including upperwing-coverts, yellowish-olive, flight-feathers and tail dusky, edged yellowish-olive; lower throat and underparts uniformly neutral grey; iris dark brown; upper mandible black, lower mandible blue-grey with small black tip; legs horn-grey. Sexes similar. Immature is like adult, but duller. Race *tetraopes* is slightly paler than nominate, especially in grey of hindcrown, nape and underparts, with back paler green, belly whiter, also bill slightly longer; *coryi* is slightly larger than nominate, also paler, with centre of breast and belly white, undertail-coverts white, and some (but not all) males with a small white spot in centre of crown. Voice. Call a brief "peee-u", often doubled. During breeding season male gives an extended, musical song; apparently also gives a canary-like whisper song, reportedly while approaching female.
Habitat. Forested areas, forest borders, thickets, semi-open areas, mangroves, gardens in dry to humid zones, including cloudforest. Sea-level to mountain summits (to c. 1800 m).
Food and Feeding. Arthropods, some fruits. Insect-seeking comprises more than 90% of foraging records, the rest fruit eating. Of five stomachs examined, three contained only animal matter and two contained both animal and vegetable matter, including seeds (5%), a large cockroach (*Blattaria*), caterpillars, nymphs of hemipterans and homopterans, coleopterans comprising darkling beetles (Tenebrionidae), weevils (Curculionidae), click beetles (Elateridae) and ground beetles (Carabidae), and snails (Gastropoda). Found in pairs and, following breeding, in small family parties or groups of up to about six individuals. At times active, at other times rather slow and deliberate. Forages from ground to treetops, using a variety of foraging methods, including gleaning from leaves and bark, and sallying to air, sometimes up to 15 m or more.
Breeding. Breeding reported in May–Jun on Gonâve and Jul in Haiti. Deep cup-nest thin-walled and frail (eggs visible from below) placed 1–9 m up in bush or tree. Clutch 2–4 eggs, greenish-white or bluish-white, with buff, brown or violet-grey marks forming wreath at larger end. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Hispaniola EBA. Locally common in Haiti; rare in Dominican Republic. In Haiti, occurs mainly W of Jacmel Depression, a small strip of low-elevation land forming E boundary of Tiburon Peninsula, an area still partly forested; reported as particularly numerous in the karst limestone forest of Macaya Biosphere Reserve, a rather poorly maintained national park in the Massif de la Hotte, and, while still numerous locally, it has doubtless declined greatly because no more than an estimated 1·5% of Haiti's original forest remains. Even these tiny remnants are under pressure as a source of firewood and for charcoal production. In Dominican Republic, found only on slopes of Sierra de Baoruco, in extreme SW, and in S part of Loma de Toro and Hoyo de Pelempito. Various predators, mostly introduced, are potential threats to the species; they include black rat (*Rattus rattus*), Norway rat (*Rattus norvegicus*), Indian mongoose (*Herpestes javanicus*) and feral cats (*Felis catus*), as well as small native raptors such as the Sharp-shinned Hawk (*Accipiter striatus*) and American Kestrel (*Falco sparverius*).
Bibliography. Anon. (2010a), Bond (1928a, 1948, 1961), Butchart & Stattersfield (2004), Danforth (1929), Dod (1978), Isler & Isler (1999), Keith *et al.* (2003), Latta (2005), Latta *et al.* (2006), Maurrasse & Rigaud (1982), McCarthy (2006), McDonald (1988), McDonald & Smith (1990, 1994), Raffaele *et al.* (1998), Richmond & Swales (1924), Rimmer *et al.* (2005), Stattersfield & Capper (2000), Townsend (2007, 2009), Wetmore & Lincoln (1933), Wetmore (1932), Wetmore & Lincoln (1932, 1933), Wetmore & Swales (1931).

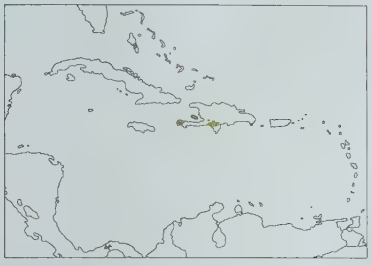
Genus *CALYPTOPHILUS* Cory, 1884

280. **Eastern Chat-tanager**

Calyptophilus frugivorus

French: Konichon dominicain **German**: Ostschmätzertangare **Spanish**: Tangara Dominicana
Other common names: Lowland Chat-tanager

Taxonomy. *Phoenicophilus frugivorus* Cory, 1883, Villa Rivas, Dominican Republic.
Molecular data suggest that genus does not belong with this family. This species was originally described in genus *Phoenicophilus*, and subsequently placed in newly erected present genus. Often treated as conspecific with *C. tertius*, the enlarged species then consisting of four races, these sharing some characters, which makes clear separation into an E species and a W species difficult; treatment as two distinct species provisional, and further study required. Two subspecies recognized.
Subspecies and Distribution.
C. f. frugivorus (Cory, 1883) – Samaná Peninsula, on N coast of Dominican Republic.
C. f. neibae J. Bond & Dod, 1977 – C mountains of Dominican Republic (E to Reserva Científica de Ebano Verde).



Descriptive notes. c. 18–19 cm; 26·3–38·6 g. Dull species with rather long and pointed bill and large, strong legs and feet; long tail, slightly rounded at tip, imparts a general shape not unlike that of a mockingbird (*Mimus*). Nominate race has crown dusky brown, becoming dark greyish-brown on side of head, with narrow broken yellow eyering (not very conspicuous) and narrow but more prominent yellowish loral mark (or line); otherwise mainly dark olive-brown above, including upperwing and tail; throat and underparts white, sides, flanks and lower underparts heavily washed greyish-brown; yellowish underwing-coverts often visible along bend of wing; iris dark brown; upper mandible black, lower mandible pale blue-grey with dusky tip; legs horn-grey. Differs from *C. tertius* in smaller size, paler plumage, yellow eyering, lack of rufescent colour on wing and tail. Sexes similar. Juvenile undescribed. Race *neibae* is smaller and darker than nominate, and has rufescent tail. Voice. Song, heard mostly at dawn, given by both sexes. Songs of the two races differ somewhat; both are excellent songsters, regarded as among the finest on Hispaniola (as is *C. tertius*). Nominate race sings a low slurred or whistled "swerp, swerp, chip, chip, chip...", sometimes accelerating into a chatter; *neibae* song similar but more varied, "weet-weet-werp chip-cheep-sweet...", sometimes ending in short trill.
Habitat. Thick undergrowth of mountain forest and dense vegetation along streams and ravines; reported as occurring especially in areas of dense undergrowth dominated by an invasive fern, *Dicranoteris pectinada*, with native bushes and trees typical of Hispaniolan cloudforest. At various elevations from lowlands to mountains, but primarily above 1000 m. Nominate race in areas below 600 m.
Food and Feeding. Feeds primarily on insects and other invertebrates; takes only very small amount of fruit (despite scientific name). One stomach contained animal matter, another held vegetable matter, including seeds, a moth (Lepidoptera), an ant (Formicidae), two hairy spiders (Araneae), a thrips (Thysanoptera) and a cockroach (Blattaria) ootheca. Found in pairs; secretive and tending to remain hidden in dense vegetation. Strongly territorial and mainly a ground-dweller, foraging on or near ground by searching leaf litter.
Breeding. Season probably May–Jul. One nest, believed to be of this species, was cup-shaped, placed 0·6 m above ground in a fern at edge of a blackberry (*Rubus*) patch; contained 1 spotted egg. No other information.
Movements. Resident.
Status and Conservation. Not assessed. Probably Vulnerable. Restricted-range species: present in Hispaniola EBA. Rare to locally common. Nominate race has not been reported in recent years, and may be extinct. Race *neibae* has reportedly declined dramatically, with recent records mainly from Sierra de Neiba, where it is still locally common, and at Ebano Verde Scientific Reserve, where it may be relatively numerous, at least in upper zone (800–1565 m). It appears that relatively little of the species' habitat lies within protected areas, and priority should be given to sites where it is known to occur. Primary threats appear to be logging and the clearing of forest or wooded areas for agricultural purposes. Considering its extremely small distribution and rapid decline, the species may be better listed as Endangered.
Bibliography. Almonte & Fernández (2002), Anon. (1998, 2010a), Bond (1928a, 1943, 1961), Bond & Dod (1977), Butchart & Stattersfield (2004), Cherrie (1896), Cory (1886), Danforth (1929), Dod (1978), Isler & Isler (1999), Keith *et al.* (2003), Latta (2005), Latta *et al.* (2006), Pregill & Olson (1981), Raffaele *et al.* (1998), Reynard (1981), Stattersfield & Capper (2000), Townsend *et al.* (2007), Wetmore & Swales (1931).

281. **Western Chat-tanager**

Calyptophilus tertius

French: Konichon d'Haïti **German**: Westschmätzertangare **Spanish**: Tangara Haitiana
Other common names: Highland Chat-tanager

Taxonomy. *Calyptophilus frugivorus tertius* Wetmore, 1929, higher slopes of Morne La Hotte, Haiti.
Molecular data suggest that genus does not belong with this family. This species was originally described in genus *Phoenicophilus*, and subsequently placed in newly erected present genus. Often treated as conspecific with *C. frugivorus*, the enlarged species then consisting of four races, these sharing some characters, which makes clear separation into an E species and a W species difficult; treatment as two distinct species provisional, and further study required. Proposed race *selleanus* (described from Massif de la Selle, in Haiti) is considered synonymous with nominate. Two subspecies recognized.
Subspecies and Distribution.
C. t. abbotti Richmond & Swales, 1924 – Gonâve I (off WC Hispaniola).
C. t. tertius Wetmore, 1929 – SW Haiti (Massif de la Hotte and Massif de la Selle) and adjacent SW Dominican Republic.
Descriptive notes. 20–21 cm; 40·2–55·3 g. Dull species with rather long and pointed bill and large, strong legs and feet; long tail, slightly rounded at tip, imparts a general shape not unlike

that of a mockingbird (*Mimus*). Nominate race has small, inconspicuous rusty loral spot, rest of head mainly rich dark olive-brown, becoming blackish on crown; upperparts, including upperwing and tail, deep rufescent brown; throat and underparts white, side of chest and side of breast to flanks and lower underparts heavily washed greyish brown; yellowish underwing-coverts often visible along bend of wing; iris dark brown; upper mandible black, lower mandible pale greyish; legs horn-grey. Differs from *C. frugivorus* in larger size, darker plumage, more rufescent upperparts, lack of yellow eyering. Sexes similar. Juvenile undescribed. Race *abbotti* is slightly smaller and more greyish-brown in colour than nominate. VOICE. Song, by both sexes, mostly at dawn, "wee-chee-chee-chee", quite similar to that of *C. frugivorus*, but weaker and buzzier. Makes "chip-chip" while foraging; "tick, tick, tick, tick..." when approaching nest.

Habitat. Broadleaf forest and dense thickets, especially in ravines and near water, much as for *C. frugivorus*. In semi-arid scrub on Gonâve I (race *abbotti*). From sea-level up into mountains; locally numerous at a few high-elevation sites.

Food and Feeding. Few data. Diet probably primarily small invertebrates, with small amount of fruit. In pairs; secretive. Details apparently similar to those for *C. frugivorus*.

Breeding. Two nests found, in mid-May and early Jun; season probably May–Jul. Nest is coarsely built, partially domed, bulky structure, placed 1–1·5 m above ground; one nest was in dense thicket, the other in a forest clearing; exterior made of small woody stems and coarse herbaceous stems, vine tendrils, moss, and foliose lichens, partially overlain by whole leaves of broadleaf species; inner cup lined mainly with fine herbaceous stems and leaf fragments; external diameter 11–13 cm, depth 5 cm. One nest contained two eggs (other nest empty, already predated); eggs pale blue with irregular brown spotting. Both adults fed chicks, male sporadically, female every 15–20 minutes when not brooding; female removed faecal pellets; male sang regularly, within 10 m of nest. Both nests ultimately predated.

Movements. Resident.

Status and Conservation. Not assessed. Probably Vulnerable. Restricted-range species: present in Hispaniola EBA. Rare to locally fairly common. Race *abbotti*, confined to Gonâve I, has not been reported for many years, and may already be extinct. Nominate race is fairly numerous locally in S Haiti and also in in SW Dominican Republic (Sierra de Bahoruco). Several reserves existed in Haiti, but unstable governments and chronic poverty have made it almost impossible to protect these sites; in addition, recent earthquake damage has caused further deterioration and environmental damage. Dominican Republic has an extensive series of protected areas, including the Sierra de Bahoruco, which offers some security for the species.

Bibliography. Almonte & Fernández (2002), Anon. (1998, 2010a), Bond (1928a, 1929a, 1943, 1961), Bond & Dod (1977), Cherrie (1896), Cory (1886), Danforth (1929), Dod (1978), Isler & Isler (1999), Keith *et al.* (2003), Latta (2005), Latta *et al.* (2006), Pregill & Olson (1981), Raffaele *et al.* (1998), Reynard (1981), Rimmer *et al.* (2008), Stattersfield & Capper (2000), Townsend *et al.* (2007), Wetmore & Swales (1931).

Genus *RHODINOCICHLA* Hartlaub, 1853

282. Rosy Thrush-tanager

Rhodinocichla rosea

French: Quéo rosalbin **German**: Rosenbrusttangare **Spanish**: Tangara Rosada
Other common names: Rose-breasted Thrush-tanager

Taxonomy. *Furnarius roseus* Lesson, 1832, Brazil; error = Caracas, Venezuela.

Relationships uncertain. Traditionally placed in present family, and such treatment partly supported by recent genetic and morphological data, but further evidence required; sometimes thought to be closest to mockingbirds and thrashers (Mimidae). Races represent at least three geographically isolated populations; furthermore, it is possible that the three races in South America (typically represented as a single geographical unit) are isolated from each other. Five subspecies currently recognized.

Subspecies and Distribution.

R. r. schistacea Ridgway, 1878 – W Mexico from S Sinaloa S to W Michoacán, also isolated population in vicinity of Laguna Tres Palos (near Acapulco, in Guerrero).

R. r. eximia Ridgway, 1902 – W Costa Rica (E San José) S to C Panama (Panamá on Pacific slope; locally on Caribbean slope in Coclé and Colon).

R. r. harterti Hellmayr, 1918 – Colombia (N & W base of Santa Marta Mts and W Guajira; E slope of C Andes in N Tolima; and W slope of E range from Norte de Santander S to Cundinamarca).

R. r. beebei Phelps, Sr & Phelps, Jr, 1949 – both slopes of Perijá Mts, on Venezuela–Colombia border.

R. r. rosea (Lesson, 1832) – N Venezuela in Sierra de San Luis, S Lara, and coastal cordillera (from Yaracuy E to Distrito Federal and Miranda, S to extreme N Guárico at San Francisco de Macaira).

Descriptive notes. 19–20 cm; 43–52 g. Distinctive species, with fairly long sharp bill and large and strong legs and feet. Male nominate race has crown and side of head slate-grey, broad carmine-rose supercilium (broad in supraloral area) narrowing and becoming white over and behind eye; upperparts and tail slate-grey, flight-feathers tinged brownish; bend of wing, and throat and underparts to undertail-coverts bright begonia-rose, sides and flanks broadly brownish-grey; iris reddish-brown; bill generally black above and mostly pale horn-grey below, considerable variation, a few have mostly yellowish bill; legs greyish-horn. Female similar to male, but with rose-red colour replaced by orange-cinnamon. Subadult male is like female, but may show patches of rose colour. Races differ mainly in coloration and in tone of red, which show "leap-frog" pattern in geographical variation, with grey-backed populations in Mexico and in South America, and intervening black-backed population in lower Central America: *beebei* is similar to nominate, but male has only a prominent supraloral spot carmine-rose, rest of supercilium white but reduced or essentially absent behind eye, female little or no white supercilium behind eye (same as on male) and with warmer, more yellowish-orange, tinge on underparts; *harterti* differs from nominate in having entire supercilium carmine-rose, but becoming very narrow behind eye; *eximia* differs rather markedly from nominate in having upperparts black (not dark grey), and supercilium pronounced, and both front of supercilium and underparts much brighter and redder, female differs in having black (not dark grey) upperparts and colder, browner underparts; *schistacea* is much like nominate, but male breast and underparts brighter and pinker, perhaps also slightly paler grey above, also wing and tail on average longer and tarsus shorter, female differs from nominate in warmer, slightly more yellowish-orange tinge below. VOICE. Songs vary somewhat geographically, but in all areas they retain distinctive quality and pattern. In Venezuela, songs, given by both male and female separately and antiphonally, include a loud, clear, very musical series of choppy but forceful phrases, "cholo, cheela, cholo, cheela, cheela..." and so on, heard especially during first half of year; may also alternate phrases, e.g. "tor-chíl-o, wachéer, tor-chíl-o..." etc. During foraging, occasionally utters a ringing "eeoo" and a short, dry "tur-ta'tup", the latter closely resembling a call of the Tawny-crowned Pygmy-tyrant (*Euscarthmus melacoryphus*).

Habitat. Thickets and tangled undergrowth on scrubby semi-arid slopes, undergrowth in thorn-forest, cane brakes along rivers, undergrowth in dry and moist woodland, and locally into humid pre-montane forest borders and dense bushy second growth. Mainly foothills and lower slopes. Sea-level to 1000 m in Mexico, 250–900 m in Costa Rica and sea-level to 1200 m in Panama; c. 100–1700 m in Colombia and 100–1450 m in Venezuela.

Food and Feeding. Takes a rather wide variety of food items. Of six stomachs examined, three contained only vegetable matter and three contained both animal and vegetable matter; contents included seeds of fruit, grass and sedges (Cyperaceae), beetles (Coleoptera, of four species), ants (Formicidae), bugs (Hemiptera), a frog-bone fragment, and grains of sand. Alone and in pairs; usually wary, remaining close to the ground and skulking in dense vegetation, where notably difficult to see well. When approached, apt to move away in a series of hops and short flights, and only rarely ascends well up in trees. Forages on ground and within dense cover, flicking aside leaves with the bill, often spending considerable periods of time in one area.

Breeding. Jul in Mexico, and reported in Jan–Sept in Costa Rica. Nest built by both sexes, a shallow, well-made cup of acacia-like rachises on a twig foundation, sometimes lined with hair-like fibres of black fungal rhizomorphs, placed c. 1 m up in dense thicket. Clutch 2–3 eggs, white or pale blue with black markings, sometimes in wreath around large end; both sexes incubate eggs and attend young; no information on duration of incubation and nestling periods.

Movements. Resident.

Status and Conservation. Not globally threatened. Fairly common very locally. Occurs in a series of small, isolated populations from W Mexico S to N Venezuela. Decidedly local and with apparently narrow micro-habitat tolerance, but sometimes surprisingly common, e.g. in dry W foothills of Santa Marta Mts, in Colombia, and in wooded areas within city limits of Caracas (e.g. Urbanización San José; Hotel Tamanaco), in Venezuela; fairly common in E foothills of Sierra de San Luis and locally elsewhere in Venezuela. Throughout its range generally restricted to dry to moist wooded sites, where often tolerates a surprising amount of habitat disturbance. Relatively little of its habitat lies within protected areas or parks, and in numerous areas dry and moist forest and scrub vegetation is rapidly being cut and converted to grassland for grazing, or being damaged or destroyed through fire and other human activities. Found in a few small protected areas, including Metropolitan Park (near Panama City), Laguna del Tabacal Municipal Park, near La Vega (Colombia), Henri Pittier and Guatopo National Parks and patches of dry to moist scrub and woodland within the metropolitan area of Caracas (Venezuela).

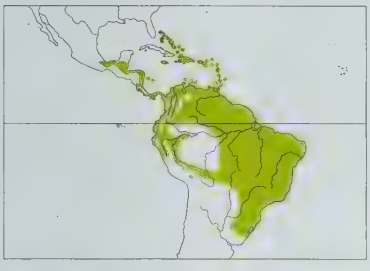
Genus *COEREBA* Vieillot, 1809

283. **Bananaquit**



Coereba flaveola

French: Sucrier à ventre jaune **German**: Zuckervogel **Spanish**: Platanero
Other common names: Common Bananaquit; Bahama Bananaquit/Honeycreeper ("*bahamensis* group")

Taxonomy. *Certhia flaveola* Linnaeus, 1758, Jamaica.
Taxonomic placement long disputed. Has often been placed in its own family, Coerebidae, and sometimes with New World warblers (Parulidae) or with buntings and New World sparrows (Emberizidae), sometimes as a subfamily. Recent molecular-genetic data do not support historically recognized family Coerebidae, but do show strong support for a monophyletic grouping that includes present genus, *Tiaris*, the Galapagos finches, and several Caribbean genera (especially *Euneornis*), all usually placed in Emberizidae but now thought to belong clearly within the thraupine lineage; genetic variation between species in this clade comparable to that within most avian genera, despite marked differences in bill morphology and feeding behaviour. Within present species, molecular-phylogenetic studies reveal three clades, "*bahamensis* group" (Quintana Roo region of SE Mexico, and Bahamas), "*flaveola* group" (Cayman Is, Jamaica and Hispaniola), and "*bartholemica* group" (Puerto Rico, Lesser Antilles, Mexico except Quintana Roo, and Central and South America), and these may be better treated as three separate species; several taxa not yet sampled, but should fall within with one of above groups on basis of distribution; placement of SW Caribbean island races *oblita* (San Andrés) and *tricolor* (Providencia) remains uncertain. Recent molecular-genetic studies point to an origin in Greater Antilles, this followed by multiple expansion phases resulting in island to mainland colonization as the species extended its range. Remarkable geographical variation, especially in Caribbean islands. Number of races likely subject to revision, some races (or groups of races) perhaps worthy of species status and others poorly separated genetically; for example, *roraimae* could be subsumed in *guianensis* and *alleni* in *chloropyga*. Forty-one subspecies currently recognized.

Subspecies and Distribution.
C. f. caboti (S. F. Baird, 1873) – SE Mexico (Quintana Roo) and islands off NE Yucatán Peninsula (Holbox, Cancún, Cozumel, and Cayo Culebra).
C. f. bahamensis (Reichenbach, 1853) – Bahamas (from Grand Bahama and Little Abaco SE to Great Inagua and Grand Turk).
C. f. sharpei (Cory, 1886) – Grand Cayman I, Little Cayman I, and Cayman Brac.
C. f. flaveola (Linnaeus, 1758) – Jamaica.
C. f. bananivora (J. F. Gmelin, 1789) – Hispaniola, Gonâve I, Petite Cayemite I and I à Vache.
C. f. nectarea Wetmore, 1929 – Tortue I, off Haiti.
C. f. tricolor (Ridgway, 1884) – Providencia I, off E Nicaragua.
C. f. oblita Griscom, 1923 – San Andrés I, off E Nicaragua.
C. f. mexicana (P. L. Sclater, 1857) – SE Mexico (from C Veracruz and Oaxaca) S on Caribbean slope (and Pacific slope in Costa Rica) to W Panama (Veraguas, including Coiba I).
C. f. cerinoclunis Bangs, 1901 – Pearl Is, in Bay of Panama.
C. f. columbiana (Cabanis, 1865) – Panama (from Canal Zone) E through C & SW Colombia (Andes from Antioquia to Huila) to S Venezuela (extreme NW Amazonas).
C. f. portoricensis (H. Bryant, 1866) – Puerto Rico.
C. f. sanctithomae (Sundevall, 1870) – Vieques I and Culebra I (off E Puerto Rico) and Virgin Is.
C. f. newtoni (S. F. Baird, 1873) – St Croix (S Virgin Is).
C. f. bartholemica (Sparrman, 1788) – N & C Lesser Antilles (Anguilla, St Martin, Saba, St Bartholomew S to Guadeloupe, Marie Galante and Dominica).
C. f. martinicana (Reichenbach, 1853) – Martinique and St Lucia (SC Lesser Antilles).
C. f. barbadensis (S. F. Baird, 1873) – Barbados.
C. f. atrata (Lawrence, 1878) – St Vincent, in S Lesser Antilles.
C. f. aterrima (Lesson, 1830) – Grenada I and the Grenadines.
C. f. uropygialis Berlepsch, 1892 – Aruba and Curaçao, in Netherlands Antilles.
C. f. bonairensis Voous, 1955 – Bonaire I, in Netherlands Antilles.
C. f. melanornis Phelps, Sr & Phelps, Jr, 1954 – Cayo Sal, off N Venezuela.
C. f. lowii Cory, 1909 – Los Roques Is, off N Venezuela.
C. f. ferryi Cory, 1909 – La Tortuga I, off N Venezuela.
C. f. frailensis Phelps, Sr & Phelps, Jr, 1946 – Los Frailes (Puerto Real) and Los Hermanos, off N Venezuela.
C. f. laurae P. R. Lowe, 1908 – Los Testigos Is, off N Venezuela.

C. f. luteola (Cabanis, 1851) – Colombia (Caribbean coast of Bolívar and Magdalena) and N Venezuela (Zulia E to Monagas, S to Apure and N Bolívar); Trinidad and Tobago.
C. f. bolivari J. T. Zimmer & Phelps, Sr, 1946 – E Venezuela (lower Orinoco Valley of Delta Amacuro, and N & E Bolívar from R Cuchivero S to lower R Paragua).
C. f. guianensis (Cabanis, 1851) – C Venezuela (lower Caura Valley) S & E across Guyana.
C. f. roraimae Chapman, 1929 – S Venezuela (N & E Amazonas, S Bolívar) and region of Cerros Roraima and Uei-tepui in Guyana and SE Venezuela.
C. f. minima (Bonaparte, 1854) – E Colombia (R Guainía) and S Venezuela (S half of Amazonas) E to French Guiana and NC Brazil (to Pará, N of R Amazon).
C. f. obscura Cory, 1913 – W Venezuela (E side of L Maracaibo, SE Zulia and below 1200 m in Andean foothills of Mérida and Táchira) and adjacent Colombia (Norte de Santander).
C. f. montana P. R. Lowe, 1912 – Venezuelan Andes (above 1200 m in Mérida and Táchira).
C. f. caucae Chapman, 1914 – Colombia in upper Cauca Valley and on slopes of C & W Andes (from Caldas S to Cauca).
C. f. intermedia (Salvadori & Festa, 1899) – SW Colombia (Nariño), W Ecuador and N Peru (from San Martín, and Loreto) E to W Brazil and S Venezuela (SW Amazonas).
C. f. gorgonae Thayer & Bangs, 1905 – Gorgona I, off W Colombia.
C. f. magnirostris (Taczanowski, 1880) – Peru in upper Marañón Valley (in Piura, Cajamarca and E Libertad).
C. f. pacifica P. R. Lowe, 1912 – W Peru (NW Lambayeque, W Libertad and Ancash).
C. f. dispar J. T. Zimmer, 1942 – C & SE Peru (from S San Martín) S to Bolivia (La Paz).
C. f. chloropyga (Cabanis, 1851) – C Peru (from Huánuco and Junín) S to C Bolivia (to Santa Cruz), then E across SC & E Brazil (to Ceará and Pernambuco, then S to Rio Grande do Sul) and S to E Paraguay, NE Argentina (Misiones) and extreme N Uruguay.
C. f. alleni P. R. Lowe, 1912 – E Bolivia (Santa Cruz) E to C Brazil (Mato Grosso).

Descriptive notes. 10·5–11 cm; 6·4–14·2 g. Distinctive for its bill shape, which is short, sharply pointed and decurved. Generally dark grey to dusky olive above, much brighter on rump, with prominent pale supercilium, white patch at base of flight feathers; throat greyish, underparts bright yellow. Sexes more or less alike. Immature is similar to adult, but paler and dingier, with supercilium dull, often yellowish, or with anterior portion yellow and posterior portion white; immatures of sooty races are similar to adults, but duller and browner. Remarkable range of geographical variation; details presented below for each of the three major clades. *Clade 1* (Bahamas, Cozumel Is: "*bahamensis* group"). Race *bahamensis* has crown dark grey, rest of upperparts plain grey, long white supercilium and small white spot at base of primaries, bill black with red gape, entire side of head, throat, and chest white, broad yellow band across mid-breast, with lower breast to undertail-coverts white; *caboti* is similar to previous, but slightly larger, blacker above, with bill broader at base and slightly less curved. *Clade 2* (Jamaica, Hispaniola, Grand Cayman Is: "*flaveola* group"). Nominate race has deep black upperparts with white supercilium, large and prominent white spot at base of primaries, small dull yellow rump patch, slaty-black throat, and dark wax-yellow underparts; *bananivora* differs from nominate in being slightly lighter in colour overall, with back blackish-slate (not deep black), throat dark grey (less slaty), underparts not so deep yellow, and white wing spot smaller; *nectarea* reported as very similar to previous, but throat and foreneck slightly darker grey; *sharpei* most closely resembles *caboti* (of clade 1, above), from which it differs in having larger bill, smaller and duller yellow rump, smoke-grey (not pale grey) throat and chest, larger white tail tips, and lores and ear-coverts with black more restricted. Two subspecies, *tricolor* and *oblita* are perhaps most similar in appearance to *sharpei*, but both have pale grey of throat spreading well down onto chest (as in *caboti* and *bahamensis*) and their true taxonomic placement remains uncertain; *tricolor* has throat and chest (not just throat) smoke-grey, and also differs from *sharpei* in shorter bill and brighter yellow rump; *oblita* is extremely similar to *tricolor*, but with grey area of throat and chest slightly darker and even more extensive, spreading to upper breast, also yellow of breast paler, more greenish-yellow, flanks slightly more greyish-olive, and bill shorter. *Clade 3* (Central America [except Cozumel], rest of Caribbean, and South America: "*bartholemica* group"). Race *columbiana* has crown and side of head black with long white supercilium, back and wings olive-tinged slate-grey, bright yellow rump, small white spot at base of primaries, white tail tips, throat grey, underparts yellow, white undertail-coverts lightly tinged cream; *mexicana* differs from previous in having rump patch duller, more greenish-yellow and smaller, and back not so dark grey; *cerinoclunis* differs little from *columbiana*, but upperparts black (little contrast with head), instead of deep mouse-grey to dark greyish-olive, also paler grey throat, darker yellow below, smaller white wing spot, and smaller white tail tips; *luteola* is nearest *guianensis*, but blackish above with conspicuous wing spot, differs from *columbiana* in entire upperparts blackish (no olive tinge), rump brighter, and lower underparts white; *montana* is nearest *columbiana*, but upperparts darker, fuscous black (instead of deep mouse-grey to dark greyish-olive), yellow of rump brighter, throat darker grey (more like *luteola*) and bill longer and stronger (*montana* is intermediate between *luteola* and *columbiana*); *obscura* differs in having lower underparts creamy, back, wing-coverts and flight-feathers paler, more dusky; *bolivari* differs in having back and wings distinctly greyish and rump whitish; *minima* is nearest *chloropyga*, but slightly darker above, rump brighter (differs from *columbiana* in slightly smaller size, back slate-grey); *guianensis* differs in having back and wings paler, more brownish-black (not olive), wing spot vestigial or absent, and no white tail tips; *roraimae* is extremely similar to last, but slightly larger, back a little darker and contrasting less with crown, and throat perhaps darker; *caucae* is much like *columbiana*, but supercilium much narrower and somewhat variegated with dusky edges. Several more S races are much paler, mainly greyish, including *intermedia*, which is exceedingly similar to *columbiana*, but underparts brighter yellow (near wax-yellow), upperparts on average slightly darker, rump generally richer yellow; *intermedia* differs from *chloropyga* mainly in conspicuous white wing spot, darker back and darker throat; *pacifica* is very like previous, but has shorter bill, back less sooty, throat paler grey (in colour nearly identical to *magnirostris*, but with much shorter bill and smaller size); *magnirostris* differs in large size, notably long tail and unusually long bill; *dispar* and *chloropyga* resemble *pacifical intermedia*, but slighter larger and essentially lack white wing spot (*chloropyga* quite greyish above and pale yellow below, with pale sandy-buff tinge on flanks); *gorgonae* is nearest *intermedia*, but side of throat and malar area finely barred dusky, back sooty, and white wing spot and tail tips very small; *alleni* is doubtfully ly indistinguishable from *chloropyga*, although may average slightly paler. More different still are several Caribbean races somewhat like *columbiana*: *portoricensis*, which differs in darker grey throat and red gape (additionally, is generally similar to *bananivora*, but differs in black upperparts, clearer slate-grey throat, and much larger, longer, white tail tips); *bonairensis* has red gape, wider white supercilium rearwards, white (not yellow) throat, back olive-brown, wing-coverts with two white wingbars, flight-feathers extensively edged white, rump pale yellow (not bright yellow); *ferryi* is nearest *luteola*, but has forehead with varying amount of white, pale greyish edging on flight-feathers, sometimes extreme base of gape red; *uropygialis* is close to preceding race (and has pale grey wing edgings), but differs in black chin and side of throat, rest of throat white (not grey), also no white wing spot, upperparts less sooty, rump patch reduced and more greenish-yellow, and well-developed red gape; *frailensis* has large white wing spot, and grey flanks and thighs; *martinicana* differs in having long bill with red gape, broad white supercilium, black side of head, side of throat and chin, with central throat whitish, little or no white wing spot and no white tail tips (in general closest to *uropygialis*, and throat similar, but differs in blacker upperparts, much shorter supercilium, and duller yellow underparts with olive-tinged sides); *barbadensis* is much like *martinicana*, differing mainly in having smaller amount of white on throat; *bartholemica* is much like previous two races (including no white wing spot), but differs most obviously in having uniformly slate-coloured throat; *newtoni* resembles *portoricensis* and *sanctithomae*, but has much darker slaty throat, and duller, more olive-yellow, rump; *sanctithomae* is very similar to *portoricensis*, but underparts brighter, cleaner yellow and flanks paler. A few S Caribbean races found on small islands are mainly black or dark olive, and utterly unlike any of the above races: *laurae* is similar in size and colour to *atrata*, but differs in lacking red gape and also in decidedly stronger, longer and less decurved bill; *melanornis* is all black like *laurae*, but smaller and with much shorter bill; *lowii* is similar in size to *melanornis*, but with red gape and olive-tinged lower underparts; *aterrima* is nearest *lowii*, mainly sooty black but with slight greenish-yellow wash on uppertail-coverts and breast and lower underparts (it also has a light morph, similar to *luteola* but with blacker upperparts and duller underparts, dark morph predominates in Grenada, light morph in Grenadines); *atrata* is exceedingly close to *aterrima*, but differs in larger size and longer, heavier bill. VOICE. Gives weak little "tsit" notes when foraging. A persistent singer, songs typically short, high-pitched series of unmusical buzzes, "chip" notes and insect-like hisses. There are hundreds of regional dialects and much individual variation within regions, which can make recognition of this species' songs difficult. Because of this extreme regional variation, songs are easily confused with those of hummingbirds (Trochilidae), *Conirostrum* species, dacnises and others, and even with insect sounds.

Habitat. Occurs in almost any shrubby or semi-open area or forest border in fairly dry to humid regions; in general most numerous in gardens, disturbed or shrubby areas, light woodland and mangroves, least numerous or absent locally in arid scrub, and generally scarce or absent in areas of extensive humid forest. Abundant in gardens and areas with flowers on many Caribbean islands and locally inside humid forest on Caribbean islands, also in dry (but not arid) to moderately humid areas across Caribbean region of N South America; fairly common in arid upper Marañón Valley in Peru, but largely or entirely absent from W Amazonia, including S Colombia, E Ecuador, NE Peru and much of W Brazil. Generally more common and widespread in lowlands, but also found locally in Andes to c. 2000 m; regularly to 2600 m near Bogotá, in Colombia (*columbiana*), 1200–1900 m or higher in Mérida and Táchira, in Venezuela (*montana*), at 1000–2400 m in upper Marañón Valley, in N Peru (*magnirostris*), and up to 2400 m farther S in Andes of Peru and Bolivia (*chloropyga*).

Food and Feeding. Feeds primarily on nectar; also takes some small fruits and berries and a few insects. Feeds many insects to young. Forages alone or in loosely associated pairs; may join mixed-species flocks, but much more often alone. Takes nectar at almost any height, from below eye level up to canopy of tall trees, by probing into flowers or by piercing, from the outside, the base of tubular flower corollas. Notably active, restless, and nervous-acting when foraging; hops rapidly, probes with high-speed movements for nectar, then quickly moves on. Much attracted to hummingbird feeders or bowls of sugar, and in many parts of Caribbean and N South America it may become very bold and tame, entering porches and open dining areas to take sugar from tables even while guests are seated.

Breeding. In Caribbean region breeding cyclical, closely correlated with onset of rains, mainly Mar–Jun, occasionally in other months; in Costa Rica reported throughout year, with peak in Jul–Sept (may vary with flowering in Caribbean lowlands); breeding records scattered throughout year in Colombia, and reported Sept–Oct in Bolivia (La Paz); may regularly produce two or more broods in some areas, e.g. on Barro Colorado (Panama) one pair attempted three broods (two successful) between Jan and Jun. Globular nest, circular entrance hole on lower side and facing slightly downward, made from grass and a wide variety of plant fibre, placed mostly 1·5–4 m up, less often to 15 m; nests sometimes reused. In all areas also builds dormitory nests (resemble sleeping nests), and breeding nests also used as dormitories when female not breeding. Clutch 2–4 eggs, dull white with brown flecks and dots; incubation by female alone, period 12–13 days; chicks fed by male and female, nestling period 17–19 days; fledged juveniles do not return to nest to sleep, but may build own dormitory nest (or use abandoned nest of other species) before acquiring adult plumage.

Movements. Generally resident. In most areas sedentary and territorial throughout year, but in dry areas local population shifts in response to flower abundance. Bahamas race (*bahamensis*) recorded as a vagrant in Cuba, mainly on offshore islets. Rare visitor to S Florida (USA).

Status and Conservation. Not globally threatened. Varies from being uncommon, as in heavily forested areas, to being abundant, as on many Caribbean islands and also locally in gardens and parks in Venezuela and Colombia. Occurs in many protected areas, but generally more numerous in settled areas where there are gardens or hedgerows with flowers. Has profited greatly from human disturbance, primarily because of its ability to use a wide variety of nectar resources, including those of many non-native species. Also, on some Caribbean islands, e.g. Trinidad and Tobago, and locally in N South America, is attracted to fruit and hummingbird feeders and readily comes to sugar bowls, where it can become extremely numerous.

Class AVES

Order PASSERIFORMES

Suborder OSCINES

Family CARDINALIDAE (CARDINALS)

- Small to medium-sized passerines with conical to very thick finch-like bill; male plumage coloration often brilliant, with pigmented reds and structural blues, females usually duller.
- 11–24 cm.

- America.
- Temperate and tropical forest, mixed woodland, savanna, arid scrub, suburban gardens; one species in grassland.
- 11 genera, 42 species, 135 taxa.
- No species threatened; none extinct since 1600.

Systematics

Cardinalidae includes some of the most beautiful and best-loved birds of the Americas. The taxa traditionally placed in this family are, with the exception of the anomalous *Parkerthraustes* and *Saltator*, a fairly homogeneous group of small to medium-sized finch-like birds ranging throughout much of North and South America. "Traditional" cardinalids have a more or less heavy, conical bill and, frequently, brilliant colours ranging from rich reds to glittering blues. They are almost entirely inhabitants of forest, forest edge and brushland, the chief exception being the grassland-specialized, sparrow-like Dickcissel (*Spiza americana*).

The distribution of the family is centred on Middle America, its area of highest diversity ranging from the south-western USA southwards to South America north and west of the Andes. Other than *Parkerthraustes* and *Saltator*, which are probably not true cardinalids, only five of the twenty-five "traditional" species breed entirely outside these limits, although the Dickcissel and the Indigo Bunting (*Passerina cyanea*) are only marginal breeders within them. Three of these five, the Rose-breasted Grosbeak (*Pheucticus ludovicianus*), Vermilion Cardinal (*Cardinalis phoeniceus*) and Yellow-green Grosbeak (*Caryothraustes canadensis*) have close relatives within the region. Only the Red-and-black (*Periporphyrus erythromelas*) and Glaucous-blue Grosbeaks (*Cyanoloxia glaucocaerulea*) represent genera absent from this core distribution, although both species have close, and possibly congeneric, relatives within it, the former being closely affiliated with *Rhodothraupis* and *Caryothraustes* and the latter being close to *Cyanocompsa*.

True cardinalids are entirely absent as breeding birds from the West Indies north of Trinidad and Tobago. The Rose-breasted Grosbeak winters sparingly in the western West Indies, and the Blue Grosbeak (*Passerina caerulea*), the Indigo Bunting and, rarely, the Painted Bunting (*Passerina ciris*) likewise spend the winter in that region. The Lesser Antillean Saltator (*Saltator albicollis*), however, is endemic to the islands of Martinique, Guadeloupe, St Vincent and Dominica.

Cardinalidae is one of the few nine-primaried oscine families with a fossil record predating human settlement. The Black-headed Grosbeak (*Pheucticus melanocephalus*) is known from the Pleistocene of Rancho La Brea, in California. D. W. Steadman and M. C. McKitrick assigned the proximal and distal ends of a right humerus and the distal end of a left humerus, collected in 1971 from a Pliocene (late Hemphillian) site in Chihuahua, in northern Mexico, to the genus *Passerina*, although they did note that the specimens were "not adequate for a definitive generic assignment".

Since the late nineteenth century, cardinals have been considered to constitute a subfamily, variously named Richmondeninae, Pyrrhuloxiinae and Cardinalinae, or a tribe, Cardinalini, of a wider Emberizidae or Fringillidae, or they have, as in the present treatment, been regarded as a family in their own right. More crucial than debates about taxonomic rank, however, are the questions of how Cardinalidae is related to the other New

Resembling an emberizid sparrow and inhabiting grasslands rather than forest and forest edge, the ***Dickcissel*** *looks out of place in the Cardinalidae. Some authors have proposed removing it, and one placed it among the New World Blackbirds (Icteridae), but its palatal structure is typically cardinalid and recent molecular-genetic studies support its placement in the present family. Its "aberrant" features may simply be adaptations to its grassland habitat. The female is smaller and duller than the male, with a much less prominent supercilium, and the black throat patch reduced to two narrow streaks.*

[*Spiza americana*, Chambers County, Texas, USA. Photo: Brian E. Small]

Pheucticus *species are large and robust, with a very heavy bill. Five species are recognized here. The plumage of the males of four species, including the* ***Black-backed Grosbeak****, is predominantly black and yellow. There have been various treatments of this "Yellow Grosbeak complex". The Yellow Grosbeak* (Pheucticus chrysopeplus) *of Mexico, Black-thighed Grosbeak* (P. tibialis) *of Middle America and Golden-bellied Grosbeak* (P. chrysogaster) *of north-western South America have been treated as conspecific, or as forming a superspecies with the Black-backed Grosbeak.*

[*Pheucticus aureoventris aureoventris*, Buenos Aires, Argentina. Photo: Matías Romano]

World nine-primaried oscines, and of which species actually belong within the family. The two questions are interlinked, as studies comparing cardinalids with other nine-primaried groups have at times used, as examples of Cardinalidae, genera that probably do not belong within its ranks. For example, a 1995 molecular study of the Emberizidae (*sensu lato*) by M. Watada and colleagues, following C. E. Hellmayr, included two "cardinals" in the genus *Paroaria* as examples of the Cardinalinae, notwithstanding the fact that in 1954 H. B. Tordoff had concluded, on the basis of skeletal morphology, that the genus was not cardinaline. Recent molecular analyses, including a 2002 study by T. Yuri and D. P. Mindell, support the placing of *Paroaria* among the tanagers (Thraupidae), although it is currently included within Emberizidae.

The species traditionally placed in Cardinalidae were generally put there because they were large-billed, often brightly coloured fruit-eaters and seed-eaters. Species having another bill morphology and different feeding habits were usually placed with other nine-primaried groups, tanagers in particular. Bill shape, however, has proven not to be a reliable phylogenetic character.

Hellmayr, in 1938, treated the group as the subfamily Richmondeninae of Fringillidae. He included within its ranks the genera *Saltator*, *Rhodothraupis*, *Caryothraustes*, *Periporphyrus*, *Pitylus*, *Gubernatrix*, *Paroaria*, *Richmondena*, *Pyrrhuloxia*, *Pheucticus*, *Hedymeles*, *Guiraca*, *Cyanocompsa*, *Cyanoloxia*, *Passerina*, *Porphyrospiza*, *Tiaris* and *Spiza*, *Hedymeles* being used for the Rose-breasted and Black-headed Grosbeaks, now included in *Pheucticus*. Tordoff removed *Gubernatrix*, *Paroaria*, *Tiaris* and *Porphyrospiza* on the basis of their palatomaxillary structure, a decision supported by later molecular studies.

Some three decades later, in his subfamily Cardinalinae for J. L. Peters's *Check-list of Birds of the World*, R. A. Paynter included the following genera: *Spiza*, *Pheucticus*, *Cardinalis*, *Caryothraustes*, *Rhodothraupis*, *Periporphyrus*, *Pitylus*, *Saltator* and *Passerina*. His expanded genus *Passerina* incorporated five genera which had been treated separately by Hellmayr, namely *Passerina*, *Cyanocompsa*, *Cyanoloxia*, *Porphyrospiza* and *Guiraca*. This treatment paralleled that used in 1888 by R. B. Sharpe, who included *Cyanocompsa* and *Cyanoloxia* in *Guiraca*. It should be noted that, in the present arrangement, *Pitylus* is subsumed in *Saltator*, and *Porphyrospiza*, no longer considered cardinaline, is included within Emberizidae.

Twenty years after Paynter's classification, in 1990, C. G. Sibley and B. L. Monroe included *Spiza*, *Pheucticus*, *Cardinalis*, *Caryothraustes*, *Rhodothraupis*, *Periporphyrus*, *Pitylus*, *Saltator*, *Cyanoloxia*, *Cyanocompsa*, *Passerina* and *Porphyrospiza* in a tribe Cardinalini within an expanded family Fringillidae.

In 2007, J. Klicka and colleagues performed the first molecular analysis in which all of the cardinalid genera recognized by Sibley and Monroe were sampled. They examined 34 of the 42 species involved, and concluded that, although there is a valid, monophyletic cardinalid clade at the core of the Cardinalidae, the family as traditionally recognized was both polyphyletic, including genera and species that belonged elsewhere, and paraphyletic, excluding taxa that seemed properly to belong within its ranks. The results of this analysis expanded the membership of Cardinalidae to include not only the warbler-like "chats" of the genus *Granatellus*, an assignment first proposed in 2002 by I. J. Lovette and E. Bermingham, but also the *Amaurospiza* seedeaters and three genera of supposed tanagers, *Piranga*, *Habia* and *Chlorothraupis*. *Granatellus* is currently placed with the New World warblers in the family Parulidae, while *Amaurospiza* is usually included within Emberizidae. Klicka and colleagues found that both *Cyanoloxia* and *Amaurospiza* were nested within *Cyanocompsa*. In contrast, *Parkerthraustes*, formerly included within the genus *Caryothraustes*, and *Saltator*, the most speciose genus in the Cardinalidae as currently constituted, appeared not to be cardinalids at all. An additional genus, *Porphyrospiza*, often included in Cardinalidae, was associated instead with *Phrygilus alaudinus*, the Band-tailed Sierra-finch, a species usually placed in Emberizidae but probably a thraupid.

Klicka and colleagues identified five subclades within the newly reconstituted family. Two, the *Habia–Chlorothraupis* and the *Granatellus* subclades, contain only genera newly assigned to Cardinalidae and currently treated within, respectively, Thraupidae and Parulidae. The "traditional" cardinalids retained in the family fall into three subclades:

1) a "masked" subclade consisting of *Piranga*, *Cardinalis* and *Caryothraustes* (including *Rhodothraupis* and *Periporphyrus*, but excluding *Parkerthraustes*);
2) a "blue" subclade consisting of *Passerina* (including *Guiraca*), *Cyanoloxia* (including *Cyanocompsa* and *Amaurospiza*) and *Spiza*; and
3) a grosbeak subclade containing the *Pheucticus* species.

It should be noted that, in the present arrangement, *Granatellus* is still treated under Parulidae, *Piranga*, *Habia* and *Chlorothraupis* under Thraupidae, and *Amaurospiza* under Emberizidae.

The upper mandible of the ***Pyrrhuloxia*** *is remarkably like that of a parrot (Psittacidae), being short, thick and deep, with a strongly curved culmen. Mainly because of this unique bill, the species was formerly placed in the monotypic genus* Pyrrhuloxia. *The mandibles of the Northern Cardinal* (Cardinalis cardinalis) *are quite different, but the bill of the Vermilion Cardinal* (C. phoeniceus) *is intermediate between the two, and the Pyrrhuloxia was returned to* Cardinalis *because of this and other arguments, including similarities in song and nest-building behaviour.*

[*Cardinalis sinuatus fulvescens*, Arizona, USA. Photo: John Cancalosi/ DRK]

Many of these conclusions, and those of earlier molecular studies, have already been accepted by the American Ornithologists' Union (AOU) and the South American Checklist Committee (SACC), although these bodies have not followed the study's proposed generic lumpings. Both have transferred *Chlorothraupis*, *Habia*, *Piranga*, *Granatellus* and *Amaurospiza* to the family Cardinalidae and removed *Saltator* to "incertae sedis" [of uncertain taxonomic position] near Thraupidae. The SACC has also transferred *Parkerthraustes*, which does not occur in North America, from Cardinalidae to a position "incertae sedis".

This radical shift in classification, if correct—and the evidence supporting it appears to be strong—means that the present text, confined to species traditionally placed in the family, can give only a partial picture of the range of morphological and ecological variation within the cardinalid clade. To avoid confusion, the genera *Parkerthraustes* and *Saltator* will generally be discussed only at the end of each introductory section.

Klicka and colleagues' 2007 study was not the first to question the traditional make-up of the Cardinalidae. An earlier molecular study by Klicka, K. P. Johnson and others, published in 2000, pointed to the misplacement of *Piranga* outside the group and of *Saltator* within it, and suggested that Cardinalini, as the authors classified it, was sister to the other four emberizid groups, namely Icterini, Emberizini, Parulini and Thraupini.

A. Grapputo and his colleagues, in a 2001 molecular study of relationships within the Emberizidae, found that the Cardinalidae, represented by the Northern Cardinal (*Cardinalis cardinalis*) and the Rose-breasted Grosbeak, clustered with the *Calcarius* longspurs and the snow buntings (*Plectrophenax*) as basal to other emberizids. These authors, however, did not examine other nine-primaried groups and used the cardinalids essentially as an outgroup, and the support for this positioning was only moderate.

Placement of the genera *Piranga*, *Habia* and *Chlorothraupis* within Cardinalidae was supported in 2002 by Yuri and Mindell, who found molecular evidence that cardinals and tanagers were sister-groups. J. Cracraft and F. K. Barker proposed that Cardinalidae and Thraupidae diverged 13·6–11·6 million years ago, during the Miocene. The cardinalid–thraupid clade, in turn, diverged from the emberizid lineage 16·3–14·1 million years ago.

With its aberrant plumage and behaviour, the Dickcissel has for a long time seemed to be out of place within the Cardinalidae. W. J. Beecher removed it from the family altogether, placing it among the Icteridae, and R. J. Raikow, on the basis of appendicular myology, considered the species to be intermediate between the emberizids and the icterids. Tordoff, however, found the palatal structure of *Spiza*, with its unfused palatomaxillaries, to be typically "richmondenine" (cardinalid). Electrophoretic data obtained by J. W. Tamplin, J. W. Demastes and J. V. Remsen placed *Spiza* as the outgroup to all other cardinalids with the exception of *Parkerthraustes*, which is probably not a cardinalid, and Demastes and Remsen suggested that *Spiza* might be closer to *Saltator*. The 2007 study by Klicka and colleagues, however, allied *Spiza* with typical members of the "blue" subclade, such as *Passerina*, suggesting that its peculiar features may simply be adaptations to its grassland habitat.

The Yellow-shouldered Grosbeak (*Parkerthraustes humeralis*) was formerly included in the genuinely cardinalid genus *Caryothraustes*, although F. M. Chapman placed it in *Saltator*. It has long been recognized, however, that this species differs from its supposed congeners in morphology, plumage and behaviour. Tamplin and his colleagues, using data from starch-gel electrophoresis, suggested that *humeralis* was not a cardinalid, and pointed out that its foraging behaviour, in which it is quiet, inconspicuous, and solitary or in pairs in mixed-species flocks, differed from the noisy, single-species flocking behaviour of *Caryothraustes*. The 2007 Klicka-led study placed it among the tanagers, although both the AOU and the SACC retain it as "incertae sedis".

W. J. Bock, in 1964, supported the submerging of *Richmondena* into *Pyrrhuloxia*, later to be renamed *Cardinalis*, on the grounds that the morphological gap, manifested by a difference in bill shape, between the Pyrrhuloxia (*Cardinalis sinuatus*) and the Northern Cardinal is bridged by the third member of the genus, the Vermilion Cardinal of northern South America (see Morphological Aspects). Bock suggested that the difference in bill shape between the two North American species might have evolved during a time when the two overlapped in habitat to a much greater degree than they do today.

Treatment of the generic boundaries within the *Passerina–Guiraca–Cyanoloxia–Cyanocompsa* complex has varied, some authorities lumping the genera in various combinations (see above) and others keeping them separate. L. L. Short considered the geographically widely separated Blue Bunting (*Cyanocompsa parellina*) and Ultramarine Grosbeak (*Cyanocompsa brissonii*) to be members of a superspecies, but Klicka and colleagues' 2007 study placed *parellina* either as a sister-species to the other members of their expanded *Cyanocompsa*, which included the Glaucous-blue Grosbeak and the "emberizid" Blue Seedeater (*Amaurospiza concolor*), or as one of the branches of a four-way polytomy including *Cyanocompsa*, *Passerina* and *Spiza*. The Ultramarine Grosbeak appeared to be most closely allied not to the Blue Bunting, but to the Glaucous-blue Grosbeak.

The status and affinities of the Blue Grosbeak, in particular, have been a point of disagreement for some time. Placed in the genus *Guiraca* by earlier authorities, such as Hellmayr, it has more recently been included in *Passerina* following Paynter's 1970 treatment. In a 1977 study of skeletal and morphological characters, J. J. Hellack and G. D. Schnell supported the maintaining of *Guiraca* and allied it more closely to *Pheucticus*, but this placement has not been supported by later studies. Klicka's molecular data suggest that the genus *Passerina* contains two lineages, a "blue" lineage consisting of the Indigo Bunting and Lazuli Bunting (*Passerina amoena*), and a "painted" lineage containing the Rose-bellied Bunting (*Passerina rositae*), Orange-breasted Bunting (*Passerina leclancherii*), Varied Bunting (*Passerina versicolor*) and Painted Bunting, and that the Blue Grosbeak fits within the "blue" lineage.

There have been varying treatments of the members of the "Yellow Grosbeak complex", some recognizing them as separate species, the Yellow Grosbeak (*Pheucticus chrysopeplus*) of Mexico, the Black-thighed Grosbeak (*Pheucticus tibialis*) of Middle America and the Golden-bellied Grosbeak (*Pheucticus chrysogaster*) of north-western South America, and others treating them as conspecific. Short considered all three to form a superspecies with the South American Black-backed Grosbeak (*Pheucticus aureoventris*), noting areas of sympatry between the latter and the Golden-bellied Grosbeak and differences in the degree of sexual plumage dimorphism among members of the complex (see Morphological Aspects).

Paynter considered the Black-faced Grosbeak (*Caryothraustes poliogaster*) and the Yellow-green Grosbeak to be conspecific but this idea has not been widely accepted. However, the 2007 study by Klicka and others indicates that the two are sister-taxa. C. W. Thompson, in 1991, suggested that the eastern and western subspecies of the Painted Bunting should be regarded as separate phylogenetic species, on the grounds that there appeared to be little gene flow between them, but the suggestion has not been taken up.

The question of species limits among cardinalids has been particularly vexing for two species pairs, the Rose-breasted and Black-headed Grosbeaks and the Indigo and Lazuli Buntings, each with one representative in eastern and one in western North America. In each case, the members of the species pair hybridize in a narrow zone of overlap at or near the western edge of the Great Plains. Presumably, eastern and western populations became isolated during the Pleistocene, but came into secondary contact at some point following the retreat of the glaciers. For the grosbeaks, especially, this situation has raised questions as to whether one or two species should be recognized, and has also, more productively, led to a number of studies on the nature and effect of evolutionary isolating mechanisms and the viability of hybrids.

The two grosbeaks have generally been maintained as separate species, although D. A. West and, later, A. R. Phillips favoured combining them. In the USA, R. L. Kroodsma found few hybrids in North Dakota, where there is little suitable habitat in what might otherwise be an area of range overlap. He demonstrated that male grosbeaks in areas of allopatry in North Dakota were more likely to attack mounted specimens of their own type than they were those of the other member of the species pair, suggesting that males, at least, discriminate between the two species on the basis of plumage. In South Dakota, B. W. Anderson and R. J. Daugherty found that Black-headed and Rose-breasted Grosbeaks hybridized within a zone some 84 km in width

Excluding the genera Parkerthraustes *and* Saltator, *which are now thought to belong outside Cardinalidae, almost all cardinalids are sexually dichromatic in plumage. The two* Caryothraustes *species are the only exceptions. The* ***Yellow-green Grosbeak*** *and the Black-faced Grosbeak* (Caryothraustes poliogaster) *have been treated as conspecific, and the race* simulans *of the Black-faced has sometimes been included in the Yellow-green. They may form a superspecies. Along with the Red-and-black Grosbeak* (Periporphyrus erythromelas), *they differ from other cardinalids also in being primarily forest-dwellers.*

[*Caryothraustes canadensis canadensis*, Les Nourages Nature Reserve, Régina, French Guiana. Photo: Olivier Tostain]

Formerly placed in the genus Caryothraustes, *the* ***Yellow-shouldered Grosbeak*** *differs significantly in its bill shape and sexually dimorphic plumage, and its quiet, inconspicuous behaviour. It is usually seen alone, in pairs or in mixed-species flocks, in contrast to* Caryothraustes, *which forms noisy single-species flocks. It now occupies the monotypic genus* Parkerthraustes. *It is no longer thought to belong with the cardinals, but its true relationships are uncertain. It has been suggested that it belongs in the tanager family (Thraupidae), but for now it is "*incertae sedis*" (of uncertain taxonomic position).*

[*Parkerthraustes humeralis*,

along the Missouri River. Even within this range, where hybrids might be expected to predominate, parental phenotypes occur in numbers too high to be explained by genetic recombination or immigration. Anderson and Daugherty found evidence that female Black-headed Grosbeaks, at least, prefer to mate with males of their own morphotype. In addition, the clutch size of hybrid pairs was lower than that of "pure" Rose-breasted or Black-headed pairs, suggesting that hybrids have reduced viability. On the basis of this evidence, the authors concluded that the two forms should be regarded as separate "semi-species". A 2009 molecular study by R. D. Mettler and G. M. Spellman re-evaluated Anderson and Daugherty's work and suggested that hybridization was less frequent than had been estimated on the basis of phenotype alone. These authors concluded that the hybrid zone between the two species was stable, and supported the conclusion that hybrids within it were less fit than their parents.

The question of the relationship between the Indigo and Lazuli Buntings has been confused by Klicka's cytochrome *b* analysis of *Passerina*, which suggested that the two were not, in fact, sister-species, the Lazuli Bunting being more closely related to the Blue Grosbeak. A later study by M. D. Carling and R. T. Brumfield, using ten nuclear loci, did, however, support the traditional sister relationship between Lazuli and Indigo Buntings. Carling, I. J. Lovette and Brumfield have recently estimated that the two species diverged about 1·04 million years ago, during the Pleistocene.

Calculations based on the presumed dates for the expansion of oak (*Quercus*) savannas in central North America suggest that Indigo and Lazuli Buntings may have been in secondary contact for at least 3500 years, and they have certainly been so for the past 120 years. Their ranges overlap within a contact zone that may be as little as 40 km wide, although Sibley and Short estimated that Indigo and Lazuli Buntings overlapped in Nebraska, in a zone more than 640 km across containing both hybrid and "pure" forms. This difference may partly reflect the way in which introgression has been measured in different studies: phenotypically, for example, as opposed to the findings of molecular-genetic analyses.

Studies of bunting hybridization have produced conflicting results, morphological analyses suggesting a high degree of interbreeding, but field studies finding that the real frequency of hybridization was much lower. Because different alleles may introgress at different rates, the presence of hybrid gene combinations may occur over a narrower or broader geographical distance, depending on which alleles are involved. Mixed pairs, especially those in which the female parent is herself a hybrid, show lower reproductive success than single-species matings, suggesting that there is selective pressure against hybridization. This pressure may be the reason why the zone of overlap is so narrow. Female mate selection appears to strengthen the isolating mechanisms between the two species. Within their zone of overlap, male Indigo and Lazuli Buntings act in some ways like members of the same

Closely affiliated with the Red-and-black Grosbeak (Periporphyrus erythromelas), *the* ***Crimson-collared Grosbeak*** *also occupies a monotypic genus,* Rhodothraupis. *This bird is a male. In the female, all the crimson areas are replaced by olive on the upperparts, and olive-yellow on the underparts. Only* Cardinalis *species possess a true crest, but a male Crimson-collared Grosbeak observed in Texas raised its crown feathers when singing, lending it a crested appearance and a cardinal-like silhouette. This species frequently wanders into south Texas from its main distribution along the Atlantic slope of north-eastern Mexico.*

[*Rhodothraupis celaeno*,
Texas, USA.

The largest genus in the Cardinalidae, as currently constituted, appears not to belong there at all but to be closer to the tanagers (Thraupidae). The genus's name, Saltator, *means "jumper" or "dancer", and refers to the birds' long powerful legs. Unlike most true cardinalids, they are subtly rather than brightly coloured. Some, including the* ***Black-headed Saltator****, have a strikingly patterned head and throat. The Black-headed Saltator's white throat patch is bordered with black, including a broad black breastband in all but one race* (lacertosus)*; in another race,* suffuscus, *the throat patch is not white, but cinnamon.*

[*Saltator atriceps atriceps*, Arenal, Guanacaste, Costa Rica. Photo: Mike Danzenbaker/ AGAMI]

species; they defend territories against each other, and they respond aggressively to each other's songs. Females, on the other hand, show a preference for mating with their "own" plumage types, or with males whose song phrases match those of their own plumage type. Interestingly, hybrid females mate randomly on the basis of plumage, but prefer Lazuli song types.

M. C. Baker and J. T. Boylan concluded, after a four-year study of colour-ringed individuals, that Indigo and Lazuli Buntings should continue to be regarded as separate species. Males of each species, however, can learn one another's song traits, and this learnt behaviour can contribute to interspecific mating and introgression, despite the genetic differences between the two species.

Recent work suggests that the measuring of mitochondrial genetic distances between closely related species pairs ("DNA barcoding") can provide a means by which to assign specimens to species, pairs with hybridizing species tending to have smaller distances than pairs with non-hybridizing species. Distance data for Indigo and Lazuli Buntings (taken outside the hybrid zone) are higher than average, but this may not be a measure of overall genetic distinctiveness.

Kroodsma speculated in 1975 that introgression in North Dakota and eastern Montana, in the north USA, was relatively high, but S. T. Emlen, J. D. Rising and W. L. Thompson, who studied populations farther south, in Nebraska, suggested that it was minimal in either direction. Carling and Brumfield's later studies, which benefited from technology that allowed detailed studies of individual loci, found that the degree and direction of introgression varied for different alleles. Mitochondrial haplotypes (mtDNA) showed greater introgression from *cyanea* (Indigo Bunting) into *amoena* (Lazuli Bunting), but alleles from two loci located on the Z chromosome showed much greater introgression in the opposite direction. In general, there was greater introgression among alleles of z-linked loci from *amoena* into *cyanea* than the reverse, suggesting that z-linked *amoena* alleles may be selected against more strongly when present in a *cyanea*-type hybrid than are z-linked *cyanea* alleles when present in an *amoena*-type hybrid.

Carling and Brumfield also found that both mitochondrial haplotypes and z-linked alleles introgressed less than autosomal alleles. Because mitochondrial haplotypes are passed on only by females, and because females are the heterogamic sex in birds, this finding supports Haldane's Rule, which predicts that, in hybrid populations, if one sex is absent, rare or sterile, it will be the heterogamic sex. In this case, female hybrid buntings should be, and apparently are, less fit than males.

By determining which alleles show the least degree of introgression—in other words, the ones most resistant to being taken up in the genomes of the other species—it may be possible to identify the specific genes involved in reproductive isolation. Carling and Brumfield found that a single locus on the Z chromosome, VLDR9, showed introgression across a band only 2·8 km wide. Mutations of the VLDR gene, which is involved in yolk-precursor formation, have been found to lower the egg-laying ability of some chickens, and it is possible that a similar effect may be involved in both the initial generation and the current maintenance of reproductive isolation between Indigo and Lazuli Buntings, despite the probability that some level of gene flow between the two has been going on for some time, even while they were in the process of speciation.

The systematics of the large genus *Saltator*, and its position within the thraupid complex to which it probably belongs, remain unclear. The genus may be polyphyletic. Hellack and Schnell, in their 1977 study, concluded that the Rufous-bellied (*Saltator rufiventris*), Streaked (*Saltator striatipectus*), Masked (*Saltator cinctus*), Black-throated (*Saltator atricollis*), Golden-billed (*Saltator aurantiirostris*) and Orinocan Saltators (*Saltator orenocensis*) bore little similarity to the other species, and recommended that the last three be removed from the genus. Further, J. P. O'Neill and T. S Schulenberg have emphasized that the Masked Saltator, with its unique colour pattern and particularly deep bill, has no obvious close relatives. One should note, incidentally, that Hellack and Schnell treated the Streaked Saltator as conspecific with the Lesser Antillean Saltator, referring to it under the latter's scientific name of *S. albicollis*; it has since become evident, from mitochondrial-DNA studies of Antillean birds and specimens from Peru and Panama, that the two are separate species (see below).

Some 30 years later, in 2007, Klicka and co-workers examined ten *Saltator* species, namely *grossus*, *coerulescens*, *striatipectus*, *atripennis*, *atriceps*, *maximus*, *nigriceps*, *aurantiirostris*, *atricollis* and *rufiventris*, and concluded that all except the last-named were properly placed in *Saltator*. They found that *rufiventris*

was nested instead with the thraupid genera *Delothraupis* and *Dubusia*. A new generic name may have to be found for this species. The Slate-colored (*Saltator grossus*) and Black-throated Grosbeaks (*Saltator fuliginosus*), allopatric species sometimes treated as conspecific, were formerly placed in a separate genus, *Pitylus*, on the basis of their bill and tarsal morphology; they differ also from all except the Thick-billed Saltator (*Saltator maxillosus*) in being sexually dimorphic. Molecular data, however, reveal that these species are nested within *Saltator*, and the 2007 Klicka-led study found *Saltator nigriceps*, the Black-cowled Saltator, to be basal to both *aurantiirostris* and *grossus*, although *fuliginosus* was not examined.

G. Seutin and colleagues, in 1993, separated the Lesser Antillean Saltator of the West Indies from the continental Streaked Saltator on the basis of data indicating that the island populations differ genetically from those of Peru and Panama to an extent greater than that found between many other congeneric passerine species. Even within the Streaked Saltator itself, however, genetic differences are considerable, populations in Peru also differing from Panamanian individuals at levels consistent with congeneric species differentiation. This suggests that *S. striatipectus* may have to be split further.

The question of species limits in *Saltator* has been vexed by lack of information, including an absence of data on zones of overlap and/or intergradation between closely related forms. The Golden-billed Saltator, for example, has been considered conspecific with both the Black-cowled Saltator (but see above) and the Thick-billed Saltator; Short treated all three as members of a superspecies, but noted that the Golden-billed and Thick-billed Saltators interbred extensively in Corrientes Province, in north-east Argentina. The Black-cowled differs, however, from the Golden-billed Saltator in vocalizations, and there seems to be little or no intergradation between the Thick-billed Saltator and the subspecies *parkesi* of the Golden-billed Saltator in Rio Grande do Sul, in south-east Brazil, where the ranges of the two meet. Short considered that the Green-winged Saltator (*Saltator similis*) and the Greyish Saltator (*Saltator coerulescens*) formed a superspecies, although they are sympatric in some areas.

Finally, the major 2007 study undertaken by Klicka and colleagues found that the Many-colored Chaco Finch (*Saltatricula multicolor*), usually treated as a member of the family Emberizidae, was nested within *Saltator*, in a position close to the Black-throated Saltator. Although the SACC has declined to include the Many-colored Chaco Finch within *Saltator*, it may consider the possibility of transferring the Black-throated Saltator to *Saltatricula* in the future.

The mysterious "Townsend's Bunting", known from a single specimen received by J. J. Audubon in 1833, and described as *Emberiza townsendi*, probably represents a Dickcissel lacking carotenoid pigments in its plumage.

Morphological Aspects

Typical cardinalids are rather stocky, medium-sized to small finch-like birds with a heavy bill and a relatively short tail, *Cardinalis*, the only crested genus in the family, being somewhat longer-tailed. Males tend to be slightly larger than females. Dickcissel males are significantly heavier than females for most of the year, the difference being due to increased amounts of protein and water. Females retain their stores of vernal fat for longer than males, reducing the difference between the sexes in summer.

Northern Cardinals are non-migratory (see Movements), but are capable of adjusting their metabolism to deal with the stresses of harsh north-temperate winters. Thermal regulation in winter appears to be more energetically costly than breeding for cardinals at the northern end of their range. Wintering cardinals studied by C. E. Sgueo in southern Ohio increased their daily energy expenditure, raised their metabolic rate and took on extra fat, increasing their average body mass from 41·5 g in summer to 47·2 g in winter. Pectoral-muscle mass did not increase.

Bill shape varies considerably even within genera of Cardinalidae. Within *Cardinalis*, the maxilla, or upper mandible, of the Pyrrhuloxia is remarkably like that of a parrot (Psittacidae), being short, thick and deep, with a strongly curved culmen and a strongly notched tomium; the species' former generic name of

The bills of saltators vary considerably in length and relative thickness, and that of the ***Green-winged Saltator*** *is shorter and less heavy than many of its congeners. In a genus consisting largely of frugivores, this species is primarily an insect-eater. It has been suggested that the Green-winged Saltator forms a superspecies with the Greyish Saltator* (Saltator coerulescens), *although the two occur together in some areas. In* chaco *vegetation, the Green-winged Saltator is found mainly in heavy brush bordering rivers, whereas Greyish Saltators occupy dense brushy areas in woodland, forest, savanna and grassland.*

[*Saltator similis similis*, Itatiaia National Park, Rio de Janeiro, Brazil. Photo: Roland Seitre]

Until 1993, the continental ***Streaked Saltator*** *and the Lesser Antillean Saltator* (Saltator albicollis) *of the West Indian islands were treated as the same species,* S. albicollis. *They were then separated on the basis of data indicating that genetic differences were greater than those between many other congeneric passerine species. But populations in Peru and Panama differ also at levels consistent with species differentiation, suggesting that further splits may be justified. The race* flavidicollis *of north-western Peru differs from other races, such as the central Panamanian* isthmicus *(shown here), in having a yellow-tinged underside that lacks streaks, except in the juvenile plumage.*

[*Saltator striatipectus isthmicus*, Coclé, Panama. Photo: Mike Danzenbaker/ AGAMI]

Pyrrhuloxia alludes to its supposed similarity to the fringillid genera *Pyrrhula* and *Loxia*. The maxilla of the Northern Cardinal is longer and less curved, with little or no tomial notch. The lower mandibles of the two species differ even more, that of the Pyrrhuloxia being deeper and having a ventral bony boss at the gonys. The bill of the Vermilion Cardinal is intermediate between those of its two congeners. Jaw musculature in the genus parallels the differences in skull and bill morphology, the longer-billed Northern Cardinal having generally larger jaw muscles that allow it to crack larger seeds, which can be held farther forward in the bill for cracking than is the case with the Pyrrhuloxia.

Northern Cardinals in Bermuda appear to have undergone shifts in bill shape since their introduction in the eighteenth or nineteenth century (see Relationship with Man). In 1901, O. Bangs and T. S. Bradlee noted that the bills of this species from Bermuda had a grooved upper mandible, a feature absent from mainland populations of Northern Cardinals but, oddly enough, present in the Vermilion Cardinal. K. L. Crowell found that Bermuda cardinals had broader, deeper and slightly shorter bills than those of mainland individuals, possibly an adaptive response to reduced competition from the limited landbird fauna of the islands.

In common with other nine-primaried oscines and fringillids, but unlike most other passerines, cardinalids produce substantial amounts of 3-methyl fatty acids in the feather waxes secreted from their uropygial glands. Unusually, and perhaps uniquely, among nine-primaried oscines, the Dickcissel produces feather waxes that are low in 3-methyl but high in 2-methyl fatty acids, the type of compounds common in most other passerine groups.

Excluding the genera *Parkerthraustes* and *Saltator*, almost all cardinalids are sexually dichromatic in plumage, often strikingly so, with bright colours largely restricted to the males. The two species of *Caryothraustes*, in which the sexes are similar, are the only exceptions. The plumage patterns of male and female Black-thighed Grosbeaks are essentially similar, females differing from males only in being slightly paler on the head and breast, with more olive scaling on the back and, usually, less white in the wing. Bright male colours include various shades of red or pink, particularly in members of the "masked" subclade, but also in some *Passerina* species; yellow, found in Neotropical *Pheucticus* and the Orange-breasted Bunting; and an array of structural blues in the "blue" subclade.

In some cases, females may develop male characteristics, such as the rose-red wing-linings found on some female Rose-breasted Grosbeaks. One Northern Cardinal ringed in Tennessee, in the eastern USA, was a bilateral gynandromorph, having its right side bright red and its left side greyish-olive. Several researchers have remarked that the strong sexual dimorphism exhibited by the Northern Cardinal, a non-migratory monogamous species in which both parents care for the young, is an exception to the general tendency for such birds to be monomorphic.

Ornamental plumage is the rule, rather than the exception, among cardinalid males. Except for the crests of *Cardinalis*, however, feather ornamentation is a matter of colour, rather than of modified feather shape. Ornamental colours may signal the health or condition of their possessor, but crest length of the Northern Cardinal appears not to do so. Instead, it probably functions as a signal of behavioural intent (see General Habits). Male Blue Grosbeaks sometimes elevate their crown feathers, giving the appearance of a crest, and a male Crimson-collared Grosbeak (*Rhodothraupis celaeno*) observed in Texas raised its crown feathers when singing, lending it a crested appearance and a cardinal-like silhouette.

Red and, presumably, yellow coloration in cardinalids is produced largely, though not entirely, by carotenoid pigments. J. Hudon has identified canthaxanthin, astaxanthin, phoenicoxanthin, doradexanthin and ε,ε-carotene-3,3'-dione among the red carotenoid pigments (4-keto-carotenoids) of the Northern Cardinal, and astaxanthin and canthaxanthin among the rose-pink breast pigments of the Rose-breasted Grosbeak. Northern Cardinals also exhibit minor amounts of rhodoxanthin, a xanthophyll.

Birds are unable to synthesize or store carotenoids, but must take them up in their diets. S. U. Linville and R. Breitwisch found that a reduction in carotenoid-bearing foods, in this case a failure of grape and other fruit crops, resulted in a slight, but significant, reduction in colour brilliance among male cardinals in Ohio. Birds can, however, transform carotenoid precursors which they obtain in their diet into different forms of pigment deposited in their feathers. Northern Cardinals derive their red pigments primarily from orange or yellow carotenoid precursors; males can grow pale red feathers even if they are fed only with yellow carotenoids.

A single male Northern Cardinal collected in Louisiana, and studied by K. J. McGraw and his colleagues, had only yellow,

In addition to their strikingly patterned head, a number of Saltator *species also have a red or orange bill. The question of species limits in* Saltator *has been complicated by lack of information, including an absence of data on zones of overlap and/or intergradation between closely related forms. The* ***Golden-billed Saltator*** *has been considered conspecific with both the Black-cowled Saltator* (Saltator nigriceps), *which has an orange or salmon-red bill, and the Thick-billed Saltator* (S. maxillosus), *which has a dark bill with some orange at the base. In the Black-cowled Saltator the sexes are alike, but the other two species have some degree of sexual dimorphism. The bill of the female Golden-billed Saltator is dusky, the black of the head and face replaced by dark brown, the supercilium and chin buffy yellow rather than white, and she has little or no pectoral band. Golden-billed and Thick-billed Saltators are reported to interbreed extensively in Corrientes Province, in north-eastern Argentina, but there seems to be little or no intergradation between the Thick-billed Saltator and the subspecies* parkesi *of the Golden-billed Saltator in Rio Grande do Sul, in south-eastern Brazil, where the ranges of the two meet. Where the Golden-billed Saltator has a white chin and throat and a very pronounced white supercilium, the Black-cowled Saltator's head and upper chest are entirely black, except for an occasional few white feathers behind the eye and on the chin. These species differ also in their vocalizations.*

[*Saltator aurantiirostris aurantiirostris*, Salta, Argentina. Photo: Neil Bowman/FLPA]

*The **Black-throated Grosbeak** (not to be confused with the Black-throated Saltator,* S. atricollis*) and the Slate-colored Grosbeak* (Saltator grossus) *were formerly placed in a separate genus,* Pitylus, *on the basis of their bill and tarsal morphology. Molecular data, however, reveal that these species are nested within* Saltator. *In both species the males are dark (slaty blue and blue-black, respectively), although they are not uniform in colour; the Black-throated has its lores, face, ear-coverts, throat and chest black. Both have a bright red bill and in both species the female is generally duller than the male, making these among the handful of Saltator species to show sexual dimorphism.*

[*Saltator fuliginosus*, Parque do Zizo Lodge, São Miguel Arcanjo, São Paulo, Brazil. Photo: Edson Endrigo]

instead of red, pigments. Presumably, this was the result of a genetic mutation that interrupted the bird's ability to complete the metabolic pathways necessary to produce the compounds responsible for normal coloration. Interestingly, a similar mutation appears to be responsible for the yellow pigments in the Western Tanager (*Piranga ludoviciana*), a species now known to be a cardinalid (see Systematics) with close, red-plumaged relatives.

The presence of carotenoids can be an indicator of a bird's condition, at least at the time when its feathers are growing. In the case of Northern Cardinals, carotenoid feather ornaments act as guides to the health and fitness of prospective mates, or serve to reinforce existing pair-bonds, for both male and female birds. Males display the bright red plumage of the upper breast to females, while females expose their red underwing-coverts to males (see Breeding). Red coloration seems not to serve as a status signal for cardinals outside the breeding season; for example, L. LaReesa Wolfenbarger found that the artificial intensifying of the birds' red colour gave them no advantage over other males at a food source.

Brown colours, such as those in the wingbars of the Blue Grosbeak, result from a mix of eumelanins and phaeomelanins. Melanin ornaments, such as the black face mask of the Northern Cardinal, are often associated with high testosterone levels and increased aggression. In a study by J. M. Jawor and her colleagues, female cardinals having a larger, darker black face mask were found to be more aggressive towards mounted models, but were also better provisioners of their young. Males with a larger face mask, however, had lower reproductive success, perhaps because they spent more time in aggressive behaviour and less in provisioning their broods.

The blue colours in the feathers of *Passerina*, *Guiraca*, *Cyanoloxia* and *Cyanocompsa* are, like almost all such colours in birds, structural, being produced by light scattering from the spongy medullary layer of feather barbs rather than by pigment. Males of *Passerina* and *Cyanocompsa* species employ structural colours, pigments including eumelanins, phaeomelanins and carotenoids, and combinations of the two to produce a range of colours, visible to birds, across a greater spectrum than the human eye can perceive.

Plumage patterns of *Cyanocompsa* are almost entirely the result of blackish eumelanin-pigmented patches and structural ultraviolet/blue colours that, together, appear to human eyes as deep blue. The ultraviolet-rich blue and turquoise plumage of the Indigo Bunting is entirely structural. Blue Grosbeaks and Lazuli Buntings add deep red-brown patches produced by phaeomelanin. The belly-patch colour of the Lazuli Bunting, appearing to humans as white, is structural, resulting from the morphology of the species' unpigmented feathers. The reds, yellows and oranges of Painted, Varied, Rose-bellied and Orange-breasted Buntings are carotenoid colours, while the Painted Bunting's green back, the purple hues of the Varied Bunting and the Rose-bellied Bunting's pink belly are apparently produced by a combination of carotenoids and structural colours.

M. C. Stoddard and R. O. Prum concluded that blue structural colours evolved only once in the "blue" subclade (see Systematics), and that phaeomelanin-based and carotenoid-based colours in subclade-members were later evolutionary developments; the authors did not examine *Cyanoloxia* or *Amaurospiza*. The ancestral plumage probably resembled the deep blue coloration of *Cyanocompsa*, the colours increasing in range and brilliance during the course of the group's evolution. Loss of brilliance in the colours of the Lazuli and Varied Buntings probably represents later, secondary developments.

In addition to white, black, violet, blue, turquoise, green, yellow, orange, brown, pink and red, the feathers of *Passerina* and *Cyanocompsa* display ultraviolet (UV), UV-yellow and UV-red, the last two being colours visible to us as yellow and red, but reflecting strongly in the ultraviolet as well. Avian eyes contain four types of cone receptor, with one sensitive to UV-violet wavelengths in addition to those responsive to blue, yellow and red, and the evolutionary significance of plumage colours may have to be understood in the context of the way in which the birds themselves perceive them, including their reaction to colours that we humans cannot see. The breast of an Orange-breasted Bunting, which reflects strongly in the ultraviolet in addition to being pigmented with yellow carotenoids, must appear an unimaginable shade to a bird's eye.

Feathers on the Blue Grosbeak reflect more strongly in the ultraviolet than in the visible blue spectrum. A. J. Keyser and G. E. Hill found that males showing little variation in their visible

blue colours varied in the intensity with which they reflected ultraviolet wavelengths. The richness of structural blue and UV colours may be affected by the rate at which the feathers grow, which is, in turn, a reflection of nutritional condition during the autumn moult. The degree of brightness of Lazuli Buntings, for example, may thus be due more to environmental factors than to direct genetic control. Keyser and Hill found that male Blue Grosbeaks that grew their tail feathers at a faster rate also had brighter rump and breast plumage, suggesting that structural brightness may be related to the individual's condition.

In another study, A. S. Barreira and her colleagues found differences in colour intensity and UV reflectance between subspecies of the Ultramarine Grosbeak occupying different habitats. Males of the subspecies *argentina*, which lives in semi-open areas, had brighter and less saturated coloration, with higher hue and lower UV reflectance, than males of the race *sterea*, which occupies densely vegetated forests where luminosity is lower and blue wavelengths prevail. The differences could be a response to the quality of ambient light in the two habitats.

Moult strategies of cardinalids resemble those of many other songbird groups, although it must be noted that, as with numerous aspects of their biology, little is known of the situation with regard to tropical and south-temperate species. Juveniles moult at least once in their first year, which results in a plumage that is replaced, in subsequent cycles, by the adult plumage. Depending on the species, adult plumage may be much the same in appearance throughout the year, being replenished by an annual moult, or there may be two moults per year, producing an alternation of breeding and non-breeding plumages. In the Orange-breasted Bunting, these two plumages are essentially identical, and brightly coloured.

Species of *Cardinalis*, *Passerina* and *Cyanocompsa*, and possibly the Rose-breasted Grosbeak in the genus *Pheucticus*, have been described as having an extra juvenile moult just after fledging and before the moult producing the first-year plumage. For individuals that hatched late in the season, these moults may overlap. In the case of young Rose-breasted and Black-headed Grosbeaks, the moult producing first-year plumage may overlap with that producing the first breeding plumage.

S. Rohwer and others have claimed that *Passerina* buntings undergo a further moult, this one involving the rectrices, the three outermost primaries and, typically, the three innermost secondaries and all of the body feathers. With Indigo Buntings this produces the first sexually dimorphic plumage, young females then resembling adult females and young males resembling males in non-breeding plumage. Indigo Buntings generally undergo this moult on the wintering grounds; fewer than 10% of individuals complete it prior to autumn migration. Moults during the first year may not be clear-cut events, however, and R. B. Payne has argued, on the basis of his studies of Indigo Buntings, that this pattern in fact represents an extended overlap between the juvenile and first-year moults, rather than a separate moult.

According to a study by T. C. Grubb and his colleagues, the rate of feather growth during moult in Northern Cardinals is affected by ambient temperature, as well as by health and condition. Rectrix growth is slowest during the winter. It is more rapid in males than in females, and in adults than in juveniles.

Northern Cardinals moult their wing and tail feathers simultaneously. Early-hatched young of this species often undergo a complete moult, but the moult of the primary feathers, which may begin after the onset of moult of the wing-coverts, becomes less extensive among individuals hatched later in the season. These late-hatched cardinals may retain their flight-feathers during the winter. In Kentucky, juvenile Northern Cardinals stop moulting at some time in November, regardless of when they began or whether the moult is complete. Those moulting into first-year plumage usually replace their wing feathers in typical passerine fashion, starting with the innermost primaries first, but retaining some outer primaries from the juvenile plumage. This is the same sequence as that followed by adult Pyrrhuloxias, whereas young Pyrrhuloxias begin the moult from a middle primary. The reason for this marked difference is unknown.

Northern Cardinals and Pyrrhuloxias moult once per year. Breeding plumage is gained not by moult, but by the wearing-away of the grey or brownish tips of the body feathers. Other North American species usually moult twice annually. The pre-breeding moult, however, may be very limited or even absent, particularly in the genus *Passerina*, in which it may be restricted

Treatment of the generic boundaries within the Passerina–Guiraca–Cyanoloxia–Cyanocompsa *complex of largely blue cardinalids has varied, some authorities lumping the genera in various combinations and others keeping them separate. The* ***Glaucous-blue Grosbeak****, here occupying the monotypic genus* Cyanoloxia, *is sometimes subsumed in* Passerina. *The dark sky-blue male is shown here; the female is warm dark brown above and more orange-brown below. The blue colours in these four genera are structural, produced by light scattering from the medullary layer of the feather barbs, rather than by pigment.*

[*Cyanoloxia glaucocaerulea*, El Palmar National Park, Entre Ríos, Argentina. Photo: Julián M. Alonso]

to the feathers of the head, particularly those around the ear-coverts, eyes, bill and throat. Other changes into breeding plumage are again the result of feather wear. Feather wear may be responsible also for the gradual decrease in UV chroma and hue in male Ultramarine Grosbeaks after the conclusion of the breeding season.

Before the onset of the breeding season, the process of abrasion wears away the buff tips of the male Blue Grosbeak's otherwise blue body feathers and the brown edgings of the body feathers of the Varied Bunting. In adult male Lazuli Buntings, the change from dull winter plumage to bright breeding dress is accomplished mostly by abrasion of the buff feather tips, but the Indigo Bunting changes to breeding plumage through an extensive moult. Second-year male Lazuli Buntings are similar in plumage to the adults, but they remain dull because, in contrast to the situation with adults, the feather tips generally do not wear away. Why this is so—whether it is the result of a hormonal difference between younger and older males, or whether there is some difference in behaviour that affects feather wear—is not understood.

Among migratory species, the post-breeding moult is generally completed on the breeding grounds or, sometimes, as may be the case with some Rose-breasted Grosbeaks, for example, it is begun on the breeding grounds and completed after migration. Most individuals moult into breeding plumage on their wintering grounds, but some Black-headed Grosbeaks may complete this moult during the course of the northward migration, and some Indigo Buntings arrive on their breeding grounds while still growing blue feathers on the head.

Some Black-headed Grosbeaks begin, or even complete, the post-breeding moult on the breeding grounds. Most, however, undertake moult migrations after the breeding season, transferring to monsoonal staging areas in the south-western USA or north-west Mexico, where the moult takes place. This strategy allows these birds to leave the nesting areas, where food may be scarce during late-summer dry spells, and take advantage of areas where a food supply sufficient to fulfil the energy needs of moulting birds is still available.

Blue Grosbeaks, Lazuli Buntings and western populations of the Painted Bunting are also known to be moult migrants. Some Lazuli Buntings fly directly to their wintering grounds in western Mexico and moult there. Most, however, begin their moult on the breeding grounds, interrupt it for migration, and complete it either in southern Baja California or in an area reaching from southern Arizona and south-west New Mexico south into northern Sonora, in extreme north Mexico. Here, in these "migratory hot spots", they remain for approximately one month while the intensity of moult increases to about twice that on the breeding grounds. Indigo Buntings are not moult migrants, and it is unclear where Indigo × Lazuli Bunting hybrids undergo their post-breeding moult.

Delayed plumage maturation, in which juvenile males take two years or longer to gain full adult colours, is recorded for the Yellow, Rose-breasted, Black-headed and Blue Grosbeaks and for the Indigo, Lazuli, Varied, Painted and Orange-breasted Buntings. Second-year male Black-headed Grosbeaks vary in plumage, ranging from individuals that resemble adult females to others that are much like older males. The difference between first-year and adult male Indigo Buntings is poorly marked. Of particular interest is the fact that Orange-breasted and, apparently, Rose-bellied Buntings, unlike other *Passerina* species, show delayed plumage maturation of females too, an unusual condition among passerines. Females of these two species retain a duller juvenile plumage until after their first breeding season.

Hill found that delayed plumage maturation among Black-headed Grosbeaks was correlated with lower testis mass in yearling birds. The small likelihood that a yearling male grosbeak will be able to win a high-quality territory and breed successfully, coupled with the need to avoid aggression from older males (see Breeding), may have favoured the evolution of delayed plumage maturation in this species.

Yearling cardinalids are, nevertheless, physically capable of breeding. After the first week on the breeding grounds, the sperm count of yearling male Indigo Buntings is equal to that of adults, and yearlings are equally likely to find mating opportunities. In the case of Lazuli Buntings, adult males are less aggressive to second-year males than to older birds. Both very bright males and dull-coloured males tend to gain better territories than those of intermediate-plumaged birds (see Breeding), suggesting that

Colour differences visible to human eyes, as described in the common names of the ***Blue Bunting*** *and the Blue-black* (Cyanocompsa cyanoides) *and Ultramarine Grosbeaks* (C. brissonii), *underestimate the degree of colour variation that birds themselves perceive. Birds have a fourth type of retinal cone that extends their range of colour perception into the near-ultraviolet (UV) wavelengths. Studies of two races of Ultramarine Grosbeak found that males of* C. b. argentina *had brighter and less saturated coloration, with lower UV reflectance, than males of* C. b. sterea. *The differences could be the result of the kind of ambient light in the environments that each uses:* argentina *is found in semi-open country,* sterea *in shadier woodlands.*

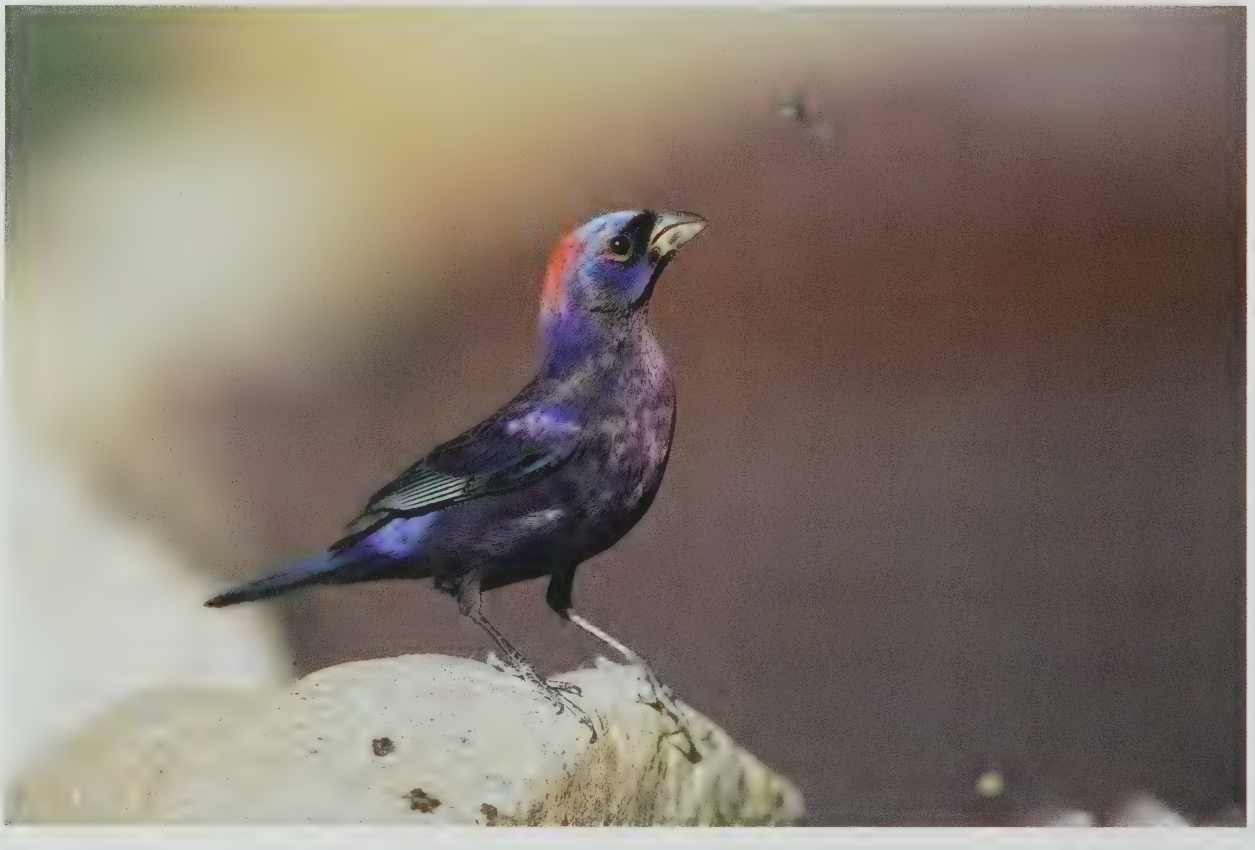
[*Cyanocompsa parellina beneplacita*, Rancho Los Ebanos, Tamaulipas, Mexico. Photo: Greg Lasley/VIREO]

delayed plumage maturation confers an advantage on yearlings by allowing them to mate without attracting adult aggression. Further, it has been suggested that delayed plumage maturation allows young males to mimic females on the wintering grounds and thereby reduce competition with adult males. V. R. Muehter and his colleagues, however, showed that adult male Lazuli Buntings could discriminate between second-year males and females, rendering the female-mimicry hypothesis unlikely for that species, at least.

Saltators, which probably do not belong in the family Cardinalidae (see Systematics), are about the size of a *Catharus* thrush, the Green-winged Saltator weighing 38–46 g. They have a relatively long tail and relatively long, strong legs, as reflected in the genus name *Saltator*, which means "dancer" or "jumper". No saltator is brightly coloured, although some have a red or orange bill and/or a striking head and throat pattern, including white superciliaries and a black-bordered throat patch. With the exception of the Slate-colored and Black-throated Grosbeaks and the Thick-billed Saltator, which have limited differences between male and female, *Saltator* species lack sexual plumage dimorphism. Some species, including the Golden-billed Saltator, have duller juvenile plumages, sometimes with streaked underparts. The bills of saltators vary considerably in length and relative thickness. That of the Thick-billed Saltator is, as its English name implies, particularly short and stout compared with the bills of other members of the genus.

The genus, as represented by the Buff-throated Saltator (*Saltator maximus*), has a well-developed M. coracobranchialis cranialis, a shoulder muscle that is vestigial in most nine-primaried oscines, but well-developed in the parulid genus *Zeledonia* and the thraupid *Catamblyrhynchus*. R. J. Raikow considered the condition in these genera to be primitive for the group. In contrast, the dorsal belly of M. obturatorius lateralis is small, a condition that Raikow considered to be derived; the muscle is large, the presumed basal condition, in the genera *Pheucticus*, *Cardinalis* and *Passerina*.

Although some saltators include leaves in the diet (see Food and Feeding), their gut morphology is similar to that of other frugivorous birds. Their only apparent adaptation to leaf-eating may be a serrated inner edge on the maxilla. Another possible morphological consequence of their largely frugivorous diet may be the fact, noted by A. Smith, that saltator carcasses decay particularly rapidly after the birds have been killed.



Habitat

Cardinalid habitats range from Amazonian rainforest to Andean forests, semi-arid scrub, temperate woodland and, for the Dickcissel, grassland and open prairie. Most species have broad habitat tolerances, generally preferring semi-open and edge situations with shrub or tree cover. Localized habitat differences can affect survival. As an example, Black-headed Grosbeaks in the Sacramento Valley of California, in the south-west USA, survived less well at a site that had been grazed by cattle and had, as a result, a less dense shrub community than they did at three other localities in the region.

A common feature of many cardinalid habitats, those occupied by Dickcissels being a possible exception, is a high degree of complexity in vegetation shape and structure. S. P. Brennan and Schnell found that abundances of Northern Cardinals, Blue Grosbeaks and Indigo and Painted Buntings recorded on Breeding Bird Survey transects in the central plains of the USA were correlated with fractal dimension, a measure of the shape complexity of habitat patches. Northern Cardinals and Painted Buntings reached their greatest density in areas with irregularly shaped patches, while abundance of all except the Indigo Bunting was correlated positively with edge density, a measure of the amount of edge in a habitat segment.

J. H. Vega Rivera and his colleagues analysed the habitat requirements of the Orange-breasted Bunting, a species confined to western Mexico, where less than 1% of its dry-forest habitat is under any form of protection regime. They found that the most important parameters for predicting the presence of the bunting were high seasonality in rainfall, low diurnal variation in temperature of no more than 9·5–15·5°C, and low elevation, from sea-level to 900 m. Within these parameters, the buntings occupied areas of forest varying widely in the extent of cover that they provided.

Indigo Buntings are historically inhabitants of successional-stage habitats, and have expanded into forest areas in southern Appalachia as new highways created additional edge situations.

Molecular data suggest that the genus Passerina *may contain two lineages, a "blue" lineage and a "painted" lineage. The* ***Varied Bunting*** *belongs to the latter. Male Varied Buntings may take two years to gain their full adult colours. In* Passerina*, the pre-breeding moult may be restricted to the feathers of the head. Instead of further moult, the brown edgings of the body feathers that give the non-breeding Varied Bunting its brownish appearance are worn away to reveal the breeding colours. Four races of Varied Bunting are currently recognized, but two are possibly too weakly differentiated to be tenable.*

[*Passerina versicolor dickeyae*, Arizona, USA. Photo: Tom Vezo/ naturepl.com]

*The **Indigo Bunting** and the Lazuli Bunting* (Passerina amoena) *belong to the "blue" lineage in the genus* Passerina. *These two species hybridize extensively. The juvenile Indigo Bunting is generally dark brown all over, though the rectrices of some males have blue edgings. The male takes two years to gain full plumage and some older males retain a substantial amount of brown on their body feathers. The adult male Lazuli Bunting changes from winter to breeding plumage mostly by abrasion of the feather tips, but Indigo Buntings undergo an extensive moult on their wintering grounds.*

[*Passerina cyanea*, Ontario, Canada. Photo: Glenn Bartley]

In north-east Texas, Indigo and Painted Buntings studied by J. G. Kopachena and C. J. Crist overlapped broadly in habitat choice, but differed in respect of habitat heterogeneity. Both are species of edge habitat, but Indigo Buntings were more likely to be found in openings in otherwise wooded areas, while Painted Buntings preferred clumps of trees in otherwise open habitat. Painted Bunting habitats provided subtle, natural edges, rather than the abrupt edges along forest clearings apparently preferred by Indigo Buntings. There seemed to be no difference between the two species in the vegetational structure of song perches that they used, although the tree species involved did differ.

Apart from the probably non-cardinalid genera *Parkerthraustes* and *Saltator* (see below), only the two *Caryothraustes* species and the single *Periporyphus* grosbeak are primarily forest-dwellers. *Caryothraustes* grosbeaks are inhabitants of the forest canopy, although the Black-faced Grosbeak will forage at lower levels in more open situations, such as shaded cacao plantations. The locally distributed Red-and-black Grosbeak keeps to lower and middle strata in the forest interior.

The dispersal of cardinalids, including *Caryothraustes* and *Periporphyrus*, in Amazonian forests has not been impeded by large rivers. In north-west Argentina, Black-backed Grosbeaks can cross habitat gaps between relict montane forest patches, presumably because they can also occupy non-forest habitats in the region. The Blue-black Grosbeak (*Cyanocompsa cyanoides*) is a bird of dense undergrowth, primarily in forest, but it will forage and nest hundreds of metres beyond the forest edge, even in cultivated maize (*Zea mays*) fields, so long as there is sufficient cover.

Some species, particularly the Varied Bunting, Vermilion Cardinal and Pyrrhuloxia, and Venezuelan populations of the Ultramarine Grosbeak, live in arid country, while the Black-backed Grosbeak prefers xeric open woodland with underbrush, usually in mountainous areas. Varied Buntings are typically inhabitants of dense thorn-scrub in canyons and arroyos (creeks), and can live in open desert provided there is a dense cover of mesquite (*Prosopis*), acacia (*Acacia*) and other woody shrubs. They do not require a source of open water. Typical habitat at the south-western edge of the Edwards Plateau, in Texas, usually includes scattered trees, which provide perches for territorial males. The Vermilion Cardinal is an arid-zone specialist whose abundance in undisturbed sites is correlated with the height of the vegetation, presumably because it moves through different levels while foraging and usually sings from the tops of columnar cacti. Genetic studies by A. Rodríguez-Ferraro suggest that it may have expanded into its range in arid regions of northern South America from a population base on Margarita Island, off north Venezuela. Encroachment by velvet mesquite (*Prosopis velutina*) into grassland habitats in south-eastern Arizona has favoured Pyrrhuloxias, which often use mesquites as nest-sites. Pyrrhuloxias have a slightly greater ability than Northern Cardinals to reduce loss of body mass during evaporative cooling, and this may give them a physiological advantage in hot, dry areas.

Dickcissels are obligate grassland specialists, but within that category they have specific habitat preferences. They prefer dense, moderately tall vegetation, with deep litter and a high proportion of forbs to provide nesting cover and support. Unlike some other grassland specialists, Dickcissels do not sing in flight, and as a consequence they require many elevated song perches. Optimal habitats include mature old fields, hay fields, fencerows, hedgerows, and moderately grazed to idle prairie.

On their breeding grounds, Dickcissels prefer the moister portions of grassy areas, including meadows and man-made habitats of clover (*Trifolium*), alfalfa (*Medicago sativa*) and other low-growing crops. They are more sparsely distributed in arid areas, and may have spread into eastern Colorado only after irrigation made possible the growing of alfalfa. R. S. Mulvihill has suggested that their regular invasions of eastern North America, including the establishment of isolated breeding populations along the eastern seaboard, may be a response to drought in the core portion of the species' range. D. B. McNair, however, failed to detect any correlation between invasions and climate (see Status and Conservation).

In Kansas, Dickcissel abundance is best predicted by examination of the vertical profile of the habitat, which relates to the availability of male song perches, while nest success is best predicted by the density of vegetation and litter cover. J. L. Zimmerman has proposed that the preference of Dickcissels for old fields is not driven by any advantage that this habitat confers on female nesting

Outside the breeding season, when it is territorial and usually seen in pairs, the ***Northern Cardinal*** *can form loose flocks. Such winter flocks have been observed throughout the species' range, reported sizes varying from fewer than ten to 60–70 individuals. The larger flocks may form during hard, snowy weather. True social behaviour is uncommon in the Cardinalidae and the flocks change in composition, new members joining and others leaving. The extent of aggression among and between age and sex classes is not known, but the possible relationship between the red coloration of males and their social status in winter flocks has been studied. Some males were artificially "reddened" and others "lightened" by means of cosmetics. This had no effect on their status in the winter flocks. Males that were naturally redder, however, had higher dominance status and gained weight at a higher rate than did subordinate males. This suggests that, although red coloration is an indicator of dominance, adult males are not using it alone as a signal of status. In a study in Ohio, USA, Northern Cardinals were found to be almost four times more abundant in urban forests than in rural ones during the non-breeding season. The results suggested that these differences in abundance stemmed from changes in habitat and micro-climate resulting from urbanization, such as the denser understorey vegetation and warmer minimum January temperatures.*

[*Cardinalis cardinalis cardinalis*, SW Ohio, USA. Photo: Dave Maslowski/ Maslowski Productions]

success. Old-field habitat does, however, provide a greater assortment of suitable nest-sites than a more homogeneous grassland would, and, since the Dickcissel is polygynous, a male can sequester a greater number of females within an old-field territory than he can in a territory on open prairie.

Dickcissel nests are more likely to be preyed on or parasitized if they are within 50 m of tree cover. This may contribute in some areas to the avoidance of woodland-edge habitats, although cropland edge apparently provides no such disadvantage. Dickcissels on reclaimed mining lands in Texas were more likely to select nest-sites farther from riparian areas, where cowbird (*Molothrus*) parasitism was at its highest, and closer to areas encroached by brush. In the Flint Hills of Kansas and Oklahoma, they reach their highest density in grasslands restored under the Conservation Reserve Program (CRP), but they have greater nesting success in unburnt hay fields, where the density is about half of that on CRP sites and the rate of cowbird parasitism is lower.

D. E. Burhans found that Indigo Buntings in Missouri were at greater risk from Brown-headed Cowbirds (*Molothrus ater*) in forest, where female cowbirds prefer to look for suitable hosts, than in old-field habitats. Within old fields, parasitism was lower at better-concealed nest-sites.

For migratory species, wintering habitat is often the same as, or similar to, the habitat that they occupy during the breeding season. Indigo Buntings, however, may winter in grasslands and crop fields, sometimes in association with such other avian species as grassquits (*Tiaris*). Large flocks, sometimes containing hundreds of individuals, feed in harvested rice fields in Belize. In La Sepultura Biosphere Reserve, in the south Mexican state of Chiapas, where wintering Indigo and Painted Buntings overlap with resident Rose-bellied and Orange-breasted Buntings, the resident species are restricted to tropical semi-deciduous forest, whereas the migrants have a much wider habitat range and also occupy pine (*Pinus*) and pine–oak forests and cloudforest.

E. Martínez-Meyer and his colleagues modelled the ecological niches of *Passerina* buntings on their breeding and wintering grounds. They concluded that in this genus, which presumably arose in Middle America, where it reaches its highest species diversity, wintering habitats are conservative while breeding-ground habitats are derived. The characteristics of winter habitats should also, therefore, be found in breeding habitats, but not necessarily vice versa. These scientists designated Lazuli and Varied Buntings as conservative "niche-followers" whose breeding habitat resembles that occupied in winter. Indigo Buntings, Painted Buntings and Blue Grosbeaks have undergone a shift in their choice of breeding habitat, so that, although characteristics of the winter habitat are good predictors of their breeding distribution, the reverse is not the case.

Pyrrhuloxias in Texas occupy winter roosts in dense mesquite thickets. Winter flocks of, at times, up to 1000 individuals feed on road shoulders, along fencerows, in weedy fields and at field edges. On their wintering grounds Dickcissels roost in huge numbers in sugar-cane (*Saccharum*) fields or tall stands of native grass, and feed primarily in cultivated rice and sorghum fields and, to a lesser extent, in native grasslands; they repair to fallow, bushy vegetation near water in order to rest between foraging bouts. All three types of habitat must be present to support a massive wintering flock of this species (see General Habits, Status and Conservation).

Both in their core range in Tennessee and in newly occupied areas in Ontario, Northern Cardinals occupy a wide range of types of woody cover. Some habitats that in Ontario supported only low population densities of the species in the 1960s held considerably higher concentrations in Tennessee. D. D. Dow suggested that the northward expansion of the species may have been limited by heavy winter snowfall, rather than by vegetation type.

In eastern Texas, Northern Cardinal territories are larger in areas having mature trees than in areas with only shrubby vegetation. This is presumably because the birds have a strong affinity for understorey foliage and because shrub cover is lower where large trees are present. In central Ohio, cardinals are more abundant in urban woods than in rural riparian forests, but are equally successful in both. Urban development, in Ohio at least, has apparently favoured cardinals by creating areas with dense exotic shrub cover, warmer minimum winter temperatures, and ready access to garden bird feeders.

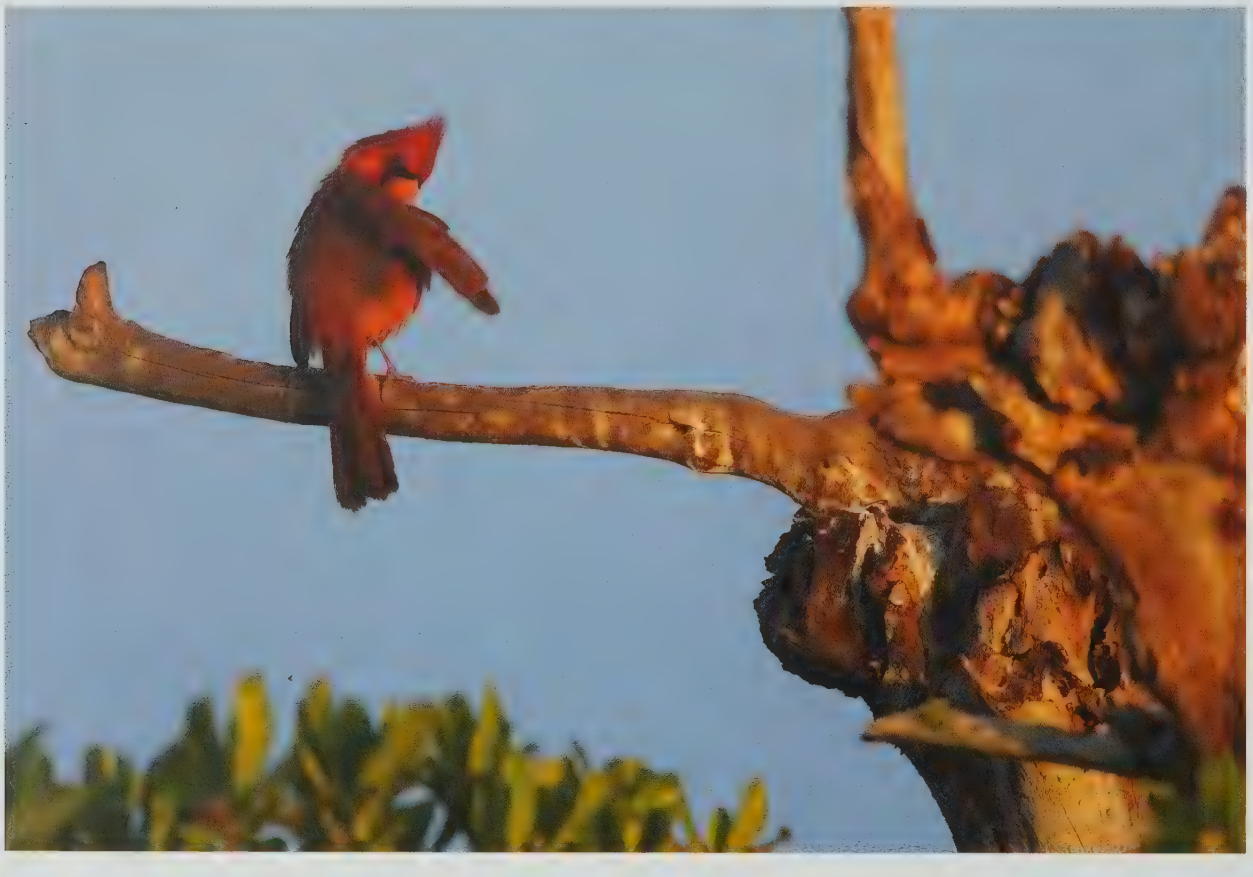
North American cardinalids are particularly aggressive during the early part of the breeding season, when territories are being established, and fights may occur even before winter flocks have started to break up. In the male ***Blue Grosbeak****, the ability to compete with other males is linked to colour intensity. Brighter individuals tend to be larger, and to have larger and better territories. Females of some species can also be territorially aggressive towards other females. Compared with many passerines, both male and female cardinals have high testosterone levels throughout the year, which may have some bearing on their aggressiveness.*

[*Passerina caerulea caerulea*, High Island, Texas, USA. Photo: Rob Curtis/ The Early Birder]

In this case the urban landscape has not functioned as an ecological "trap", luring the birds into an area where they would fare poorly. The abundance of anthropogenic edge habitat, however, may create such a trap for Indigo Buntings. A. J. Weldon and N. M. Haddad, using experimental forest plots in South Carolina, found that these birds preferred patches with increased areas of edge, but did less well within them. Plots with greater edge areas experienced higher rates of nest predation in the first half of the breeding season; Indigo Buntings breeding within them fledged significantly fewer young than pairs in rectangular plots of the same area, even though predation increased in the rectangular plots in the late nesting period.

Farther north, in southern Canada, tree-harvesting in woodlots in southern Ontario appeared to have no effect on the breeding success of Rose-breasted Grosbeaks, as measured by nest survival, numbers of young fledged and other parameters. Woodlots which had suffered heavy removal of wood had more fruit-bearing trees, and higher densities of grosbeaks, than undisturbed sites. In all of the woodlots studied, both disturbed and undisturbed, however, the grosbeaks failed to produce enough young to replace themselves. Populations of Rose-breasted Grosbeaks require large tracts of continuous forest in order to thrive. Overharvested woodlots, with their increased food supplies, may also act as ecological traps, attracting birds into a population sink.

Northern Cardinals introduced in Hawaii are found throughout disturbed lowland forests and gardens, and also, less commonly, in native forest. They are most common in dry, open, lowland forests with a grassy or shrubby understorey. They have reached the Alaka'i Swamp, at 1200 m elevation on Kauai, and there is a record at 4055 m near the summit of Mauna Kea, on the main island of Hawaii. Some populations may nonetheless have declined since the 1970s. Those in open forests in the Hakalau Forest National Wildlife Refuge, on the island of Hawaii, showed a stable to declining trend in the 21 years after the refuge was established, in 1987. In the Puna forests on the same island, cardinals have benefited from the widespread presence of illegal marijuana (*Cannabis sativa*) plantations, which provide them with canopy openings and sources of seed.



Mention must be made also of the two anomalous, probably non-cardinalid genera *Parkerthraustes* and *Saltator*. The first of these contains only one species, the Yellow-shouldered Grosbeak, which is an inhabitant of tropical forest interiors. The 16 species of *Saltator* range widely in habitat preferences, although most are birds of arid to semi-arid open country, including second growth and farmland. Green-winged Saltators in Argentina have recently spread into Entre Rios and the north-eastern part of Buenos Aires Province, where they are frequently found in farmlands. In *cerrado* habitat in São Paulo State, in south-east Brazil, G. Levy found that Black-throated Saltators occupied grassland savanna with low shrub density in preference to more heavily vegetated areas. Trees greater than 2 m in height, which the saltators use as sentinel posts, are important elements in the habitat.

Buff-throated Saltators in Costa Rica are denizens of second-growth thickets and forest edge, including forest treetops near the borders of clearings. In contrast, the Streaked Saltator avoids areas with continuous tree cover, being apparently restricted to areas of tangled vegetation, such as overgrown pastures. Where Green-winged and Greyish Saltators occur together in *chaco* vegetation, the former is found mainly in heavy brush bordering rivers, whereas Greyish Saltators occupy dense brushy areas in woodland, forest, savanna and grassland.

Some saltators, including the Slate-colored and Black-throated Grosbeaks and the Black-winged Saltator (*Saltator atripennis*), are primarily forest-dwellers. The rare and localized Masked Saltator occurs in humid montane forests in Ecuador and Peru, where it seems to depend largely on stands of *Podocarpus oleifolius*. In Colombia, these stands make up less than 10% of the total forest area within this saltator's range, so that the species occurs at very low densities in that country (see Food and Feeding, and Status and Conservation). The Rufous-bellied Saltator, confined to Bolivia and north-western Argentina, is a high-altitude specialist, found in montane scrub generally above 2500 m, including *Polylepis* woodland and adjacent cultivated areas.

General Habits

There is little information on the amount of time that cardinalids budget for daily activities. Captive cardinals studied by T. W. Shuman and her colleagues spent 74% of their time perching,

The range of feather-maintenance behaviour observed in the Northern Cardinal includes preening, sunning, anting, bathing in pools and puddles and rain-bathing, though apparently not dust-bathing. ***Northern Cardinals****, which are sedentary, have been found to carry twice as many potentially feather-degrading microbial species as do migratory birds visiting the same sites. Preen-gland (uropygial) oil, sunlight and formic acid from ants (Formicidae) may all have anti-bacterial properties.*

[*Cardinalis cardinalis floridanus*,
Everglades National Park, Florida, USA.
Photo: Tim Laman]

In the genus Passerina, *both the* ***Indigo Bunting*** *and the Varied Bunting* (Passerina versicolor) *have been observed to sun-bathe. Indigo Buntings also indulge in passive anting, allowing ants (Formicidae) to crawl over them, and at least go through the motions of active anting, placing the ants on particular parts of their bodies. Dust-bathing has never been recorded for this species, and seems rare or absent in the Cardinalidae. However, there is an account of a male Blue Grosbeak* (P. caerulea) *dust-bathing in a site used for this purpose by House Sparrows* (Passer domesticus), *before flying to a sunny perch and preening.*

[*Passerina cyanea*, N Kentucky, USA. Photo: Dave Maslowski/ Maslowski Productions]

13% feeding and 5% flying, and the remainder interacting, drinking and in miscellaneous unspecified activities. In the USA, male Dickcissels on their breeding grounds in Kansas spent 17–21% of their time in foraging, 8–10% in resting, and at least 50% in singing, the last figure rising to more than 70% during the major influx of returning females in spring. Other Dickcissel activities varied in intensity throughout the breeding season; territory defence occupied 3·5% of the birds' time during the second week, but diminished to near zero as the season progressed. The time devoted by females to maintenance activities rose during the incubation and brooding periods. Time budgets were affected by ambient temperature. At temperatures above 94°F (34·4°C) Dickcissels spent more time resting, especially if humidity was high; below 50–60°F (10–15·6°C) they increased their evening foraging bouts, presumably to gain enough energy to maintain body temperature through the night.

The flight of cardinalids is strong, and for many species it is also undulating, but that of Indigo Buntings and Dickcissels is direct. Cardinalids fly or hop from branch to branch in trees and bushes, and Blue Grosbeaks may sidle rapidly along a branch in the manner of a parrot. When on the ground, cardinalids generally hop, rather than walk, although Dickcissels both hop and walk and Painted Buntings may include walking in some of their displays.

Like other passerines, cardinalids preen regularly. Rose-breasted Grosbeaks, in addition to wiping the bill, ruffle their head feathers and rub the side of the face against a perch, especially after bathing. So far as is known, cardinalids, except very young birds, perform head-scratching by the indirect method, one leg being brought over the wing. When no more than nine days old, young Rose-breasted Grosbeaks may attempt to scratch the head with a leg held over the wing, often losing their balance in the process.

When water is available, bathing is a frequent maintenance activity of the members of this family, Rose-breasted Grosbeaks, for example, bathing at least once a day when possible. In contrast, the Dickcissel is the only member of the family that has been recorded dust-bathing. Anting has been recorded for the Northern Cardinal, the Black-faced Grosbeak and the Dickcissel. Northern Cardinals, Rose-breasted Grosbeaks and, at times, Indigo and Varied Buntings sun-bathe. Northern Cardinals indulge in this activity even on very warm days, and it has been suggested that the extra heat may make feather parasites more active and easier for the bird to remove while preening.

The roosting habits of several of the cardinalids are known. Northern Cardinals and Pyrrhuloxias roost in dense shrubs or thickets. In addition to nocturnal roosting, Northern Cardinals may spend a substantial portion of the daylight hours at a roost, resting and perhaps occasionally sleeping. Their roosts are not

When undisturbed, a sunning ***Northern Cardinal*** *will lean to expose first one flank and then the other to the sun. One moulting female was seen to spend a full 15 minutes first facing and then with her back to the early-morning sun, with bill slightly open and feathers ruffled. She interspersed sun-bathing with long bouts of preening. Northern Cardinals indulge in this activity even on very warm days, and it has been suggested that the extra heat may make feather parasites more active and easier for the bird to remove while preening.*

[*Cardinalis cardinalis*, Texas, USA. Photo: Rolf Nussbaumer/ naturepl.com]

Like other cardinalids, the ***Painted Bunting*** *is reported to bathe frequently, often after drinking. In a nine-year study of wintering Painted Buntings in Florida, however, birds which came regularly to raised feeders and drank occasionally at a ground-level birdbath only rarely bathed. Bathing has been described in detail for Rose-breasted Grosbeaks* (Pheucticus ludovicianus). *The bird hops in to the water and, as soon as its lowered head and breast break the surface, it beats its wings, throwing water over a wide area. The already thoroughly wet bird flings more water over itself with sideways flicks of its head and vertical movements of its spread tail. Some preening takes place during bathing. After bathing, the bird shakes its feathers and may preen and scratch, sometimes touching its preen (uropygial) gland with its bill and then its bill with its foot, presumably to transfer oil to those parts of the plumage that cannot be reached by preening and must be scratched instead.*

[*Passerina ciris pallidior*, Texas, USA.
Photo: Derrick Hamrick/ ImageBroker/FLPA]

shared. Pyrrhuloxias in Texas settle in roosts in mesquite–hackberry (*Prosopis–Celtis*) thickets from approximately half an hour after sunset to just before total darkness. Indigo Buntings have been seen to fly into dense *Rubus* bushes at dusk during the breeding season; on their wintering grounds, they roost in tall grass, in marshes and in trees.

The most expansive roosts in the family, however, are those of Dickcissels on their wintering grounds, where the numbers involved can be enormous. Roosts of between 20,000 and 2,950,000 individuals have been recorded in Venezuela, with an average roost size of about 580,000. Roost-sites may be used for several years. Most birds remain in the same roost throughout the winter, although some shifting from roost to roost may occur. Most of this species' roosts are in fields of sugar cane, although the birds may be forced to move when the plantations are harvested or rotated to other crops. They may also roost among cattails (*Typha*), in tall grass or shrubs, in small trees and in fallow rice fields. During the spring migration, thousands of Barn Swallows (*Hirundo rustica*), Collared Sand Martins (*Riparia riparia*) and Bobolinks (*Dolichonyx oryzivorus*) sometimes join Dickcissels at their roosts.

Dickcissels observed in Venezuela arrived at the roost about 90 minutes before sunset and began to depart 10–30 minutes after sunrise. In late March, shortly before migration, they left earlier and returned later. Roosting individuals perched on sugar-cane leaves or crowded together on the ground. It took nearly an hour for large roosts to fill up with birds, but in the morning the same roosts would empty in less than 30 minutes as hundreds of thousands of Dickcissels left together, spiralling upwards into tornado-shaped funnels or broad columns.

In addition to their enormous nocturnal roosts, Dickcissels gather close to their feeding grounds in daytime roosts containing from a few tens to hundreds of thousands of individuals. Here, they rest between morning and late-afternoon foraging bouts. Only rarely were daytime roosts sited in sugar cane, the preferred habitat for nocturnal roosts.

Roosts of this species in Trinidad, though considerably smaller than those in Venezuela, are still substantial. R. ffrench conservatively estimated that one roost contained some 66,000 individuals, and on another occasion he saw perhaps 100,000 birds fly out of the cane field within a period of little more than two minutes. The Dickcissels usually flew to their roosts at a height of about 60–90 m above the ground, breaking formation above the roost and cascading into it with a great deal of noise as the wind rushed through their flight-feathers. As in Venezuela, they normally left their roosts about 25 minutes after sunrise, their departure time becoming earlier in the three weeks before the spring migration. Unlike those observed in Venezuela, however, they did not rest on the ground while roosting but, instead, perched at least 2 m up in the sugar cane, perhaps in order to avoid snakes, rats and introduced small Indian mongooses (*Herpestes javanicus*).

True social behaviour is uncommon in the Cardinalidae. Black-faced and Yellow-green Grosbeaks are regularly found throughout the year in groups of up to a dozen or more, sometimes joining with other species. They apparently do not defend territories. The groups may consist of members of an extended family, larger groups being assemblages of family units (see Breeding).

Gaping is an aggressive display used by both Northern Cardinals and Rose-breasted Grosbeaks. In the case of the cardinals, it forms part of the "head-forward display" used at higher levels of aggression, in which an individual faces his opponent, lowers his body, flattens his crest, opens his bill, and may quiver or spread his wings. While giving this display, the bird may be silent or may give a variety of "chip" notes and other calls (see Voice). Rose-breasted Grosbeaks perform a similar display.

Alarmed or aroused Lazuli, Indigo and Varied Buntings perch upright, with the body feathers sleeked and the crown feathers raised. Among Indigo Buntings, the most intense response to playback of the species' recorded song appears to be a "moth flight" display, in which the male quickly flies towards the source of the sound, fluttering his extended wings as he lands on a nearby perch,

*The **Indigo Bunting** has been seen to bathe by making repeated dives from a perch above the water. After rolling its body and flicking its wings in the shallow water, the bird returns to its perch, shaking off water on the upswing, then vibrating its feathers, before plunging in again. Indigo Buntings also bathe in the more conventional manner, standing in shallow water and ducking the head while flicking water over themselves with their wings.*

[*Passerina cyanea*, High Island, Texas, USA. Photo: Rob Curtis/ The Early Birder]

and crouches with fluffed body plumage, lowered and rapidly quivering wings and raised beak and tail.

S. M. Lanyon and C. F. Thomson described a repertoire of displays by Painted Buntings, most of which are performed also, with variations, by Indigo and Lazuli Buntings. They include upright posture, bowing (a display apparently lacking in Indigo and Lazuli Buntings), wing-quivering, and fluffing of the body feathers, and are used in aggressive encounters, as well as in courtship (see Breeding).

Among ten North American cardinalid species, the maximum recorded longevity in the wild ranges from 4 years, for the Dickcissel, to 15 years 9 months, for the Northern Cardinal, with a mean maximum of 8–9 years. Two Indigo Buntings returned to A. Downer's feeding station in Jamaica for eight successive years. These figures probably do not, however, reflect either average life expectancy or potential longevity. R. B. Payne and L. L. Payne estimated the mean survival rate of colour-ringed Indigo Buntings in southern Michigan to be only 2·04–2·41 years; the mean survival of individuals recovered from ringing programmes fell within these limits. At the other extreme, the oldest Rose-breasted Grosbeak recovered in the wild was 12 years 11 months in age, but captive specimens have lived to an age of 24 years. Similarly, the maximum recorded longevity in the wild for the Black-headed Grosbeak is 9 years 1 month, but a captive specimen lived for 25 years. In the case of Pyrrhuloxias, males may have higher survival rates than females: in an unpublished study, of 44 individuals recaptured more than a year after ringing, 73% were males.

Domestic cats and hawks (Accipitridae) and owls (Strigidae) of various species have been recorded as taking cardinalids as prey. Pyrrhuloxias form a small part of the diet of Ferruginous Pygmy-owls (*Glaucidium brasilianum*) in Texas, and Great Grey Shrikes (*Lanius excubitor*) attack and kill Northern Cardinals. Rose-breasted Grosbeaks may be seized by Sharp-shinned (*Accipiter striatus*) and Cooper's Hawks (*Accipiter cooperii*). A grey squirrel (*Sciurus carolinensis*) has been recorded killing and eating an adult Northern Cardinal. Northern Cardinals adjust their foraging strategy to the potential presence of a predator; in one experiment, cardinals that were offered high-quality food at feeders away from cover visited these more frequently than they visited feeders with lower-quality food near cover, but they reversed this preference if exposed to calls of a predator, Cooper's Hawk, at two-hour intervals.

The enormous winter roosts of Dickcissels are magnets for predators. In Trinidad, ffrench noted Merlins (*Falco columbarius*), Common Barn-owls (*Tyto alba*) and an Aplomado Falcon (*Falco femoralis*) hunting at Dickcissel roosts. Further, at roosts in Venezuela, G. D. Basili and S. A. Temple recorded five species of falcon, seven hawks, two owls and three mammals as preying on Dickcissels; the mammals were the jaguarundi (*Puma yagouaroundi*), greater grison (*Galictis vittata*) and tayra (*Eira barbara*). Merlins were the most common diurnal predators, with 1–5 birds at each roost, and Common Barn-owls the most conspicuous by night.

Saltators, probably not true cardinalids (see Systematics), are in general not particularly well known. In the *llanos* of Venezuela, Greyish and Orinocan Saltators were found to spend 77% to 80% of their time in sitting, singing and preening. Buff-throated and Green-winged Saltators have been recorded anting, and A. F. Skutch observed a Buff-throated Saltator while it visited an arboreal ant nest for this purpose.

It appears that the social systems and display repertoires of saltators have never been thoroughly studied. Black-headed (*Saltator atriceps*) and Buff-throated Saltators are regularly found in small, loose groups, but whether the members of these groups are related to one another is not known. Other species, including the Greyish and Streaked Saltators, are usually found only singly or in twos and threes. H. Sick described a display of the Black-throated Grosbeak in which the bird opens its wings to show off the white underwing-coverts, but he did not mention the context in which this display occurs.

Black-throated Saltators associate in groups of 2–6 individuals. Helpers at the nest have been recorded for this species, suggesting that these groups consist of family members. One individual, very occasionally accompanied by one other, usually sits sentinel on a prominent exposed perch while other members of the group forage near the ground. Sentinels studied by J. Ragusa-Netto in the Brazilian *cerrado* stayed at their posts for usually less than six minutes, but sometimes for as long as 30 minutes, constantly turning

*The **Northern Cardinal** is reported to establish such regular bathing habits that it will continue to use water that has become stagnant or very muddy even when clean water is available nearby. Northern Cardinals continue to bathe in the winter, sometimes in melted-snow water, and there is a description of five males and two females taking turns to bathe while surrounded by five feet of snow. This species shows remarkable cold tolerance. Two individuals were subjected to reductions in temperature of 3°C every 20 minutes; after three hours, when the temperature had reached as low as –17°C, the birds had still not become hypothermic.*

[*Cardinalis cardinalis cardinalis*, SW Ohio, USA. Photo: Dave Maslowski/ Maslowski Productions]

Outside the hectic breeding period, the ***Northern Cardinal*** *can spend a considerable amount of time loafing or even sleeping in the daylight hours, sometimes remaining in its roost for much of the day. In the winter, these lengthy periods of inactivity help to conserve energy. Typical roost-sites are quite low down in thickets, among dense shrubs or in conifers. Adult Northern Cardinals do not share their roosts, but newly fledged nestmates may roost in the same vicinity.*

[*Cardinalis cardinalis cardinalis*, Whitnall Park, Milwaukee, Wisconsin, USA. Photo: Thomas Lazar/ naturepl.com]

the head from one side to the other. Individuals spent longer at their post if there were a large number of raptors in the area. If a bird of prey came into view, the sentinel sounded an alarm call, causing all fellow group-members to head for cover. Except during the breeding season, Black-throated Saltators constitute one of four nuclear species in mixed flocks in the *cerrado*. Up to 33 other species may be present in a saltator-centred flock, these other species taking advantage of the warnings that saltator sentinels provide. While Ragusa-Netto recorded attacks on mixed flocks by American Kestrels (*Falco sparverius*) and Aplomado Falcons, he never saw an attack on a group consisting of saltators alone.

Little is known about predation suffered by saltators. A Golden-billed Saltator was among the prey items found in the nest of a Ferruginous Pygmy-owl in Argentina.

Voice

The voices of cardinalids are among their most attractive features. Most species have musical songs consisting of a series of whistled or warbled phrases, as well as a repertoire of often sharp and distinctive calls. The primary song of the Dickcissel is an exception, being a short, dry series of notes from which the bird's English name is derived.

Very little research has been undertaken on the vocalizations of Mexican, Central American and South American cardinalids, some of which appear to have complex song repertoires. For example, Skutch describes the Blue-black Grosbeak as "a superb and generous songster". This species, the song of which varies geographically across its wide range, is deserving of further study. The singing behaviour of some North American species has, however, been the subject of intensive research, particularly by R. E. Lemon and G. Ritchison on Northern Cardinals, as well as recent work on the acoustics and neurophysiology of cardinal song by N. Fletcher and his colleagues, and studies by Ritchison on Black-headed Grosbeaks, by K. D. Groschupf and C. W. Thompson on Varied Buntings, and by R. B. Payne and his students at the University of Michigan on Indigo Buntings.

O. N. Larsen and F. Goller, in their investigation of song production in the syrinx of the Northern Cardinal, used endoscopic examination of the syrinx and electrical stimulation of syringeal muscles in living birds. Their studies represented the first direct examinations of the oscine syrinx in action. They demonstrated that, contrary to earlier belief, the medial tympaniform membranes are not the principal sound-generators in the syrinx; birds were able to produce nearly normal song even if these membranes were incapacitated. Instead, sound is generated primarily by the syringeal labia. The syrinx is controlled, according to Larsen and Goller, by complex interaction between muscles in combination with the complicated suspension of the cartilaginous framework upon which they act. Larsen and Goller found no significant difference in the operation of the syrinx between the Northern Cardinal and the American Crow (*Corvus brachyrhynchos*) and Brown Thrasher (*Toxostoma rufum*), the only other oscines that they examined. It is likely, therefore, that the syrinx in cardinalids functions in a manner typical for songbirds in general. The left side of the syrinx produces lower frequencies, up to about 3·5 kHz. Both sides are used for higher frequencies, but airflow is often reduced or even eliminated on the left side, suggesting that the right side specializes in producing higher-frequency sounds. Most song syllables, however, span the frequency ranges of the two sides, and the shift of airflow from one side to the other usually cannot be detected.

Beyond the syrinx, the volume and tonal quality of cardinal song are influenced by the degree of beak gape, and by complex movements of the hyoid apparatus that affect the position of the tongue, larynx and trachea. Northern Cardinals, like other songbirds, possess an oropharyngeal oesophageal cavity between the top of the trachea and the open beak which can be actively distended by movements of the hyoid skeleton. T. Riede and his colleagues have shown that the cavity acts as a resonator, the sounds filtered within it being radiated through the beak. By adjusting its size, the bird can effectively "set" the cavity so that its resonance frequency matches the fundamental tone produced in the syrinx, resulting in a nearly pure-tone song.

Female Northern Cardinals, as well as males, sing, both in duet with their mates and on their own. Jawor and S. A. MacDougall-Shackleton have demonstrated that the HVC, RA, and Area X nuclei in the brains of Northern Cardinals, which form part of the song-control system, vary in volume both seasonally

*The song of the **Rose-breasted Grosbeak** is usually given from a high perch, and occasionally in flight. These birds may begin singing as early as 03:00 hours, but they sing less frequently, if at all, during the midday hours. The female also sings when nest-building, relieving the male at the nest, incubating or brooding. In Quebec, Rose-breasted Grosbeaks had repertoires of 15–23 syllables per bird. Songs were of nine to eleven syllables, and consecutive songs often began with the same syllables, but overall sequences were usually different. Some individuals incorporate song elements of other species into their songs.*

[*Pheucticus ludovicianus*, Long Point, Ontario, Canada. Photo: Glenn Bartley]

and between the sexes. They are largest early in the breeding season, and male nuclei are 1·5–2 times larger than those in females. Both differences are small compared with those in bird species that have more restricted singing periods or whose females do not sing. In addition, females of a number of other cardinalids are known to sing, as documented for the Rose-breasted and Black-headed Grosbeaks and the Black-faced, Red-and-black and Blue-black Grosbeaks; female Pyrrhuloxias sing, albeit rarely, and females of two of the saltator species also do so (see below). Blue-black Grosbeak partners sing to each other while building the nest and while the female is incubating. In contrast, females of the Dickcissel and of *Passerina* species, including the Blue Grosbeak, are not known to sing.

Northern Cardinals may begin to produce soft warbling sounds at as early as three weeks of age, but true song development does not really get underway until the following winter and spring. Initial warbling is succeeded by disorganized, rambling subsong, which slowly develops into a more controlled plastic song as syllable morphology develops. Plastic song crystallizes into recognizable adult song when the bird reaches about ten months of age.

Some simple cardinalid sounds may be innate, but complex song elements are apparently learnt during a sensitive period early in life. The maintenance of song structure, once learnt, requires memory reinforced by auditory feedback. Experiments demonstrated that the songs of artificially deafened Northern Cardinals gradually deteriorated with time, and deafened juvenile Black-headed Grosbeaks were unable to develop normal song.

Hand-reared Northern Cardinals raised in isolation developed simple, but not more complex, two-note or three-note phrases resembling those of adults, but isolated Indigo Buntings were unable to produce more than a few adult-type syllables. In the case of the Northern Cardinal, both sexes learn song from their parents during their first summer. Females, but not males, require exposure to adult songs early in life in order to learn. Captive male cardinals younger than 15 weeks in age, if exposed to recordings of adults, developed songs that copied some or all of the recorded songs in the following spring; in addition, they invented material of their own. Male Northern Cardinals were able to learn songs played to them when they were 5·5–9 months of age.

A. Yamaguchi, working with captive Northern Cardinals, found that the sensitive period begins at a fairly similar time for both sexes, on average 27·8 days for males and 22·4 days for females. The learning period, however, lasts much longer for males, ending at an average age of 214·9 days, the corresponding figure for females being 71·1 days. Despite this, the number of songs in the birds' eventual repertoires was roughly the same. Each sex appeared capable of learning the song of the other, and showed no preference for learning the song of its own sex. The

*The song of the **Golden-bellied Grosbeak** is a rich carolling, similar to that of the Highland Hepatic-tanager* (Piranga lutea). *The number of syllables in the song repertoires of the different cardinalid genera varies substantially.* Cardinalis *species may use only ten or so syllables, but* Pheucticus *species generally have larger repertoires: 15–23 for Rose-breasted Grosbeaks* (Pheucticus ludovicianus) *(above) and up to 37 for male Black-headed Grosbeaks* (P. melanocephalus). *Female Black-headed Grosbeaks have smaller repertoires, on average 12–13 syllables.*

[*Pheucticus chrysogaster chrysogaster*, S Ecuador. Photo: Jon Hornbuckle]

difference between the sexes may be related to the need for the male, but not the female, to be able to learn the songs of neighbouring conspecifics after it settles on territory.

Male Indigo Buntings can learn syllables from recorded songs up to 18 months of age. In Indigo and Lazuli Buntings, the patterns of song-learning are quite different from those in the Northern Cardinal. Female buntings do not sing, and males learn their songs not from their parents, but from other males, although it is possible that they may learn some basic elements of song from hearing their fathers. Fledgling Indigo Buntings between 15 and 60 days old begin to sing highly variable, apparently random subsong; this crystallizes into adult song during the first spring, about 9–11 months after the bird hatched. Lazuli Buntings produce subsong at 29 days, but stop singing in winter and begin subsong again in early spring.

Approximately 80% of male Indigo Buntings copy the song of another male, usually an adult rather than another yearling, that they encounter when establishing their territories during their first spring season. As the birds normally settle several territories away from their natal area, only very rarely is the song that of their father, or, indeed, that of any close relative. Members of a song neighbourhood, defined as an area in which all males sing essentially the same song, are, by and large, unrelated males.

The advantages of learning from a neighbouring bird may be considerable. First-year individuals that copy a neighbour's song have greater success in mating, nesting and bringing off fledged young than those that do not. Possibly, they are able to deceive older birds, which may otherwise chase them off, into thinking that they are established territory-holders. Adults whose songs match those of their neighbours also tend to be more successful than adults that are not part of a song neighbourhood. The breeding success of Indigo Bunting males, however, seems not to depend on the specific song neighbourhood to which a bird belongs.

The choice of which individual bird to copy, out of a number of singing males that may be present, apparently requires intensive social interaction between learner and tutor. These interactions can include repeated chases across territorial boundaries and also countersinging, the younger bird matching the song of the older one.

Apparently, the 20% of Indigo Buntings that do not copy from a neighbour learn their first song before arriving on their territory. Some first-year males, and approximately 5% of older males, may switch songs in the course of a season, either when changing territories or, for older birds, if no neighbouring males match their current song. Adult Indigo Buntings appear to retain the ability to learn a new song even after their original song crystallizes, permitting them to replace it with another that matches that of a neighbouring male. This relearning ability contributes to the development and differentiation of song neighbourhoods.

The songs and other vocalizations of saltators have not been studied in detail. Some are notably fine singers, but others have been described as harsh or raucous. The song of the ***Orinocan Saltator*** *is a loud, rollicking series of notes, often given by more than one bird at a time. Black-throated Saltators* (Saltator atricollis) *may sing together as a group during the early hours of the morning. This species and possibly also Orinocan Saltators sing antiphonal duets, in which phrases given by one bird are replied to with similar phrases by another. One author has recently recommended that both of these saltators be removed to a different genus.*

[*Saltator orenocensis rufescens*, Coro, Venezuela. Photo: Jonathan Newman]

Song structure generally correlates with the acoustic properties of a bird's habitat. A study including twelve species of saltator found that long-distance songs in open country generally contained more elements, with wider bandwidths, higher frequencies and shorter lengths, than those from closed habitats. On the other hand, the songs of birds of the forest interior, such as the ***Slate-colored Grosbeak****, tended to be composed of whistled notes with slowly modulated frequencies, which perhaps took advantage of the reverberation in such closed habitats to create a louder and longer signal.*

[*Saltator grossus grossus*, Cristalino Jungle Lodge, Alta Floresta, Mato Grosso, Brazil. Photo: Edson Endrigo]

The number of syllables shared by cardinalid populations diminishes with distance. In Venezuela, the song of the ***Ultramarine Grosbeak*** *is described as a rich series of rising and falling warbles, while in Brazil it is said to be flowing and melodious, alternating higher and lower cadences. Within Brazil, the forest-dwelling subspecies* sterea*, shown here, also has louder and more complex songs than the subspecies* argentina*, found in semi-open country. This may be a compensatory response by* sterea *to low ambient light and dense vegetation in its habitat, where plumage signals may be harder to detect.*

[*Cyanocompsa brissonii sterea*, Jacutinga, Minas Gerais, Brazil. Photo: Geiser Trivelato]

Lazuli Buntings in their first spring may copy song segments from as many as ten other males before settling on a stable song. Second-year Painted Buntings rarely establish territories, but they may sing from within the territory of another male; in this instance, the pattern of song-learning is not known.

In general, the song repertoires of cardinalids contain a number of syllables, sometimes composed of more than one subunit, arranged in various combinations to produce different song types. The number of syllables used in any one song varies among species. Pyrrhuloxias frequently use only a single syllable, while Rose-breasted Grosbeaks may incorporate 9–11 syllables into a single song.

The song of the Blue-black Grosbeak has not been studied in detail, but Skutch and others have noted that it is frequently in two parts, a series of often descending tonal whistles being followed by a rapid warble at lower volume. The concluding warble is not audible at so great a distance as is the first part of the song, suggesting that it may function only in close encounters.

Syllable construction, length and amplitude vary among members of the family. In Canadian studies, most of the 14 syllables identified in the songs of Northern Cardinals at London, southern Ontario, were simple whistles, frequently slurred downwards or upwards, the lower frequencies ranging between 1·2 kHz and 1·6 kHz, but the upper frequencies varying more widely, from 1·2 kHz to 6·2 kHz. Mean syllable length varied from 0·10 seconds to 0·48 seconds. Rose-breasted Grosbeak syllables in Quebec ranged in frequency from 1·5 kHz to 4·0 kHz and had an average duration in the range 0·24–0·28 seconds.

When incorporated into a song, the intervals between successive syllables given by Northern Cardinals and Rose-breasted Grosbeaks relate directly to the duration of the preceding syllable. With Rose-breasted Grosbeaks, the interval is some three times longer than the syllable itself. Syllables in the songs of Painted and Orange-breasted Buntings are evenly spaced, whereas the intervals in songs of Indigo, Lazuli and Varied Buntings are more irregular. Syllables may be repeated in sequence. *Cardinalis* may repeat the same syllable a number of times, and Indigo Buntings normally sing each syllable at least twice before moving to the next. Rose-breasted Grosbeaks rarely repeat syllables consecutively.

The number of syllables in a song repertoire varies. *Cardinalis* may have only ten or so syllables available; in various studies, 8–21 were recorded for male Northern Cardinals, 8–10 being a frequent total, and 1–14 have been recorded for male Pyrrhuloxias. *Pheucticus* species, so far as is known, generally have larger repertoires: 15–23 for Rose-breasted Grosbeaks and 14–37 for male Black-headed Grosbeaks. *Passerina* buntings studied have much larger repertoires, of over 100 syllables: 127 are recorded for Indigo Buntings, more than 140 for Lazuli Buntings and 101 for Varied Buntings. The songs of 17 Blue Grosbeaks studied by B. Ballentine and her colleagues were each composed of a single song type, made up of combinations of 11–19 unique elements producing 5–138 minor variants. In contrast, the song of the Dickcissel consists of repetitions of only two phrases, "dick" and "cissel", occasionally with a third, a trill. Most male Dickcissels sing only a single song type, with slight variations in the number of elements utilized. They repeat the same song throughout the breeding season, and return to it in successive years.

Northern Cardinals organize their syllable repertoires into 8–12 song types. These can vary significantly in terms of the number of notes per song. The songs of the congeneric Pyrrhuloxia are organized in a similar manner, although the song syllables are generally shorter. Pyrrhuloxias have a higher number of song types than cardinals, but they are mostly repetitions of a single syllable, rather than consisting of two or three syllables per song, as is common among Northern Cardinals.

In the songs of both cardinals and Rose-breasted Grosbeaks, the order of syllables is not random. Short syllables tend to be repeated more often than longer ones during a single song. Certain syllables are used most frequently at the beginning of a song, and cardinals have distinctive syllables, including a dry "chirr", normally heard only last in the sequence. The "chirr" note may be a measure of fitness. Cardinals are able to replenish their air supply by taking extremely short "mini breaths" if syllables are repeated at rates lower than 16 per second. The elements of the

*In older individuals of the **Varied Bunting**, the series of short, rapidly repeated phrases which form the song is more prolonged than in younger birds. Adults of the closely related Indigo Bunting* (Passerina cyanea) *appear to retain the ability to learn a new song from their neighbours even after their original song "crystallizes". This relearning ability contributes to the development and differentiation of song neighbourhoods. Approximately 80% of male Indigo Buntings copy the song of another male, usually an adult, that they encounter when establishing territories during their first spring. But while the details of the Indigo Bunting's song are learnt, this learning seems to be primarily a refinement of a basic pattern which the bird is able to produce without ever having heard another Indigo Bunting sing. Five male Indigo Bunting nestlings were hand-reared in isolation from adults. As soon as the young began to sing subsongs, at between 15 and 60 days, they were isolated until their songs were fully developed. The early subsong was a variable warbling. During the first spring this "crystallized" into a series of figures which eventually formed the entire song of each bird. Siblings developed completely different songs. The songs of these isolated birds contained very few figures which were closely comparable to those of wild birds in the area where they hatched. However, the general characteristics of figure shape, spacing and repetition, and even the interval between songs, were all close to those of free-living birds.*

[*Passerina versicolor dickeyae*, Santa Cruz County, Arizona, USA. Photo: Brian E. Small]

*The **Lazuli Bunting** has a repertoire of over 140 syllables to draw on, but most individuals learn only a single song, the "crystallized song", and retain it throughout life. Lazuli Buntings may copy song segments from as many as ten other males in their first year, before settling on a stable song. The song is similar to that of the Indigo Bunting* (Passerina cyanea), *but twice as fast and less strident. In areas where only one of these species is found, it is usually indifferent to playback of the other's song. But where both occur, each reacts aggressively to the other's song, although they may also use phrases borrowed from the other. Hybrids between these species are relatively common because, at least to some degree, females use learnt song traits of males in mate choice.*

[*Passerina amoena*, Hollister, California, USA. Photo: John Sorensen]

"chirr" follow each other more rapidly than that, so that a male's ability to produce and prolong the "chirr" may be an indicator of his lung capacity and cardiovascular fitness.

Individual repertoires, once established, may persist unchanged for long periods, both through the breeding season and from year to year. Male Northern Cardinals have been recorded singing the same song types for four years.

Northern Cardinals may repeat the same song for a number of minutes, often with slight variations in volume and structure, but normally beginning with the same syllable. Such a sequence is referred to as a song "bout". Songs within a bout are separated by intervals of varying lengths. Cardinal singing bouts in Kentucky contained an average of 18·5 songs each. When an individual does switch to a different song type, its choice may be determined to a great extent by the song that has preceded it, so that the structure of singing over long periods of time is highly organized. Males in Kentucky varied in the number of notes per song and the number of songs per bout, perhaps reflecting differences in male quality. Oddly, in eastern Texas, Northern Cardinals having smaller repertoires and less complex song types held higher-quality territories and fledged more young, the reverse of what one might expect.

Male and female Northern Cardinals have similar song-syllable repertoires and combine them in the same way. However, Yamaguchi has shown that male and female songs are not identical, and that the birds themselves can distinguish the sex of the singer. Females may sing longer songs on the nest. Male cardinals repeat syllables in their repertoire in a more stereotyped manner than females, and female songs have a greater harmonic amplitude than those of males.

Female Black-headed Grosbeaks have smaller song-syllable repertoires, on average 12·8 syllables, as opposed to 24·5 for males, and their songs, with a mean of 4·5 syllables per song, are simpler and shorter than those of males, which have a mean of 10·3 syllables per song. Females tend to use fewer syllables from their available repertoire in each song. In one example, a female had a repertoire of 14 syllables, but just three of these accounted for 82% of the syllables that she used in her song.

Testosterone may function in controlling the precision and stereotypy of male songs. The songs of female Black-headed Grosbeaks are more variable than those of males, perhaps as a result of reduced testosterone levels. Occasionally, a female will sing a male-type song, with shorter syllables separated by smaller intervals, possibly in order to mimic a male (see Breeding). In general, males and females in a population share only about 10% of their song repertoires, but mated partners may share 25% of their syllables.

By selecting among their large repertoires of syllables and rearranging the order of these within a song sequence, *Passerina*

*Some cardinalids are primarily arboreal foragers, while others, such as the **Orange-breasted Bunting** and the Northern Cardinal* (Cardinalis cardinalis), *spend considerable time in feeding on the ground. Orange-breasted Buntings hop across field edges and roadsides, constantly tilting their head and peering. Most species in the family are opportunistic omnivores. While there are no published data on the diet of Orange-breasted Buntings in the wild, their food choices in captivity cover a spectrum from seed-eating, including canary seed and white millet, and fruit-eating (apples) to insects, such as ant pupae (Formicidae).*

[*Passerina leclancherii grandior*, Colima, Mexico. Photo: Pete Morris]

At the end of the breeding season, flocks of ***Blue Grosbeaks*** *assemble to feed on grass and weed seeds, and on cereal grains. They forage both on the ground and in vegetation, and frequently join flocks of other granivorous birds, including other* Passerina *buntings (as seen here). On migration, they may be found in rice fields, and wintering birds in Guatemala have been seen foraging on waste grain in mule corrals. During breeding, their diet is more animal-based. At all times of year they are opportunistic feeders, ready to take advantage of temporary abundances of prey, such as cicadas (Cicadidae) during emergence periods, and pursuing swarming winged insects and seizing them by flycatching.*

[*Passerina caerulea caerulea*, High Island, Texas, USA. Photo: Rob Curtis/ The Early Birder]

species can create an enormous variety of individual songs. Blue Grosbeaks usually begin their songs with the same combination of elements, introducing variation by rearranging and adding elements in the second half of the song. Unlike *Cardinalis* and *Pheucticus*, Indigo Buntings appear to lack any stereotyped system for organizing the sequence of syllables within a song, except for a single short note given to open a sequence. Some Lazuli Bunting syllables can occur anywhere in a song, but others tend to occur in specific positions; this species' songs usually end with "buzzes", which are rapidly frequency-modulated elements, or with "beeps", which are usually paired chevron-shaped figures with one overtone.

Indigo and Lazuli Buntings regularly use selected syllables more than once in a single song, but Painted and Varied Buntings rarely do so. Only about 1% of syllables are repeated in Painted Bunting songs, and Orange-breasted Buntings apparently never use the same syllable twice within a single song. Although the variety of individual songs that they could produce is potentially extremely large, most Indigo and Lazuli Buntings learn only a single, complex advertising song, the "crystallized song", and retain it throughout life; a few males, however, learn songs from neighbours and may remain "bilingual". In addition, Indigo Buntings occasionally sing longer songs incorporating extra syllable types, as well as low-amplitude squeaky songs incorporating high-frequency elements; the latter are employed in territorial encounters. D. Margoliash and his colleagues have established that adult Indigo Buntings commonly sing squeaky, highly variable "plastic" songs resembling those given by young birds during the critical learning period. These low-amplitude songs tend to be uttered in separate singing bouts later in the day than advertising songs, which are usually given at first light. There is evidence that Indigo Buntings may use these plastic songs to practise and "store" additional, newly learnt song syllables before incorporating them into stereotyped song.

Unlike Indigo and Lazuli Buntings, Painted and Varied Buntings do not develop a single crystallized song. Painted Buntings have 4–5 song types, differing primarily in the structure of individual figures in the middle of a song. Individual Varied Buntings have repertoires of some 9–35 syllables, first-year males having smaller repertoires than older birds. From these syllables the birds construct songs of varying length. They may add or remove syllables, particularly near the end of a song. Varied Buntings almost never repeat individual songs in the course of a song bout. This extreme variety makes it difficult to classify song types or to determine differences among individuals. Birds from different areas differ in the ordering of song syllables, so no song is shared among populations.

Vocal mimicry is rare among cardinalids, and very few examples have been documented. An adult Rose-breasted Grosbeak heard while singing at Savoy, in Massachusetts, intermixed, among phrases of its own primary song, imitations of the primary songs and calls of Red-eyed Vireos (*Vireo olivaceus*), Eastern Towhees (*Pipilo erythrophthalmus*) and Northern Cardinals, as well as the "mew" call and a scold note of the Grey Catbird (*Dumetella carolinensis*).

With birds, song structure generally correlates with the acoustic properties of the habitat and, in particular, with the ability of song signals to resist degradation with distance. The relatively unmusical song of the Dickcissel may be a response to the increased carrying properties of harmonic, as opposed to tonal, sounds in open habitats. Tonal sounds carry better in closed habitats, and the song of the Blue-black Grosbeak, an interior-forest bird, is composed of pure tone-like sounds with a narrow frequency range. The forest-dwelling subspecies *sterea* of the Ultramarine Grosbeak has louder and more complex songs than those of the subspecies *argentina*, which lives in semi-open country. The difference in this case may be a compensatory response by *sterea* to low ambient light in its habitat, where plumage signals may be harder to detect.

A study in eastern Texas by M. E. Anderson and R. N. Connor revealed significant differences in frequency and amplitude, correlated with habitat type, among song syllables of Northern Cardinal populations located only 4·5 km from one another. Individuals in younger tree stands lacking a closed canopy produced sounds with a greater degree of frequency modulation than those voiced by cardinals in older stands. In contrast, a study of Indigo Buntings by R. Hylton and R. D. Godard found no significant difference between the songs of birds in open habitats and those in

forest habitats. This may reflect insufficient acoustic differences between the two types of habitat. It may, however, be a result of the social learning system for Indigo Bunting song, in which an individual may copy the song of a neighbour even if that neighbour is in a different habitat type.

P. L. Tubaro and D. A. Lijtmaer found similar patterns in the songs of the Red-and-black Grosbeak, *Pheucticus* grosbeaks and twelve species of *Saltator* (see below). Vocalizations used in short-distance communication, such as the wide-band duet songs of the Greyish Saltator, were an exception, but signal degradation is less of a problem if the recipient is close to the singer. Long-distance songs in open country generally contained more elements, with wider bandwidths, higher frequencies and shorter lengths, than those from birds in closed habitats. Songs in mixed habitats were intermediate in structure. The songs of birds of the forest interior, where reverberation can cause overlap between the echoes of a note and the following song elements, tended to be composed of whistled notes with slowly modulated frequencies. Tubaro and Lijtmaer suggest that the long, slowly modulated terminal notes in songs of the Black-winged Saltator, Black-throated Grosbeak, Slate-colored Grosbeak, Green-winged Saltator and Red-and-black Grosbeak may benefit from reverberation, which could help to create a louder and longer signal.

Song production is subject to the control of hormones, particularly testosterone and luteinizing hormone. Increased singing by laboratory-reared male Northern Cardinals in their first spring was associated with a significant increase in levels of these hormones. The increase was much smaller in females. Wild male cardinals have also been found to have far higher breeding-season levels of testosterone and luteinizing hormone than wild females.

Blue-black Grosbeaks may sing throughout the year in lowland forests of southern Central America, but at El General, in Costa Rica, which is more than 600 m above sea level, singing begins only in February or March, reaching its peak during the breeding season, from April to September, and diminishing during the heavy rains of October and November.

Indigo Buntings begin singing just before or during spring migration, and stop prior to moult and the autumn migration. The singing rate of Painted Buntings declines by more than half between the males' arrival on the breeding grounds and the arrival of the females, and declines by half again after pairing. Ballentine and her colleagues found that Blue Grosbeaks sang longer dawn choruses and sang with increased song rates, as well as using more versatile arrangements of elements and maintaining more syntax consistency, during the dawn chorus of their females' fertile period than in the non-fertile periods. C. Lattin and Ritchison found that Blue Grosbeaks sang at highest rates prior to pairing, then maintained relatively high rates up to the egg-laying stage, but sang at lower rates during the incubation to fledgling stages. Male Black-headed Grosbeaks reach their peak of singing between the time of arrival on the breeding grounds and the stage at which egg-laying is completed. The frequency of song drops off sharply from the time of laying until the young fledge, although it may rise to pre-laying levels if the nesting attempt fails. Females of this grosbeak begin to sing only during incubation, and their level of singing increases sharply once the young leave the nest. When the young reach independence, both males and females stop singing.

Dickcissels and Northern Cardinals may sing throughout the year, but do so more frequently during the breeding season. In Arizona, both cardinals and Pyrrhuloxias begin singing in mid-February, reaching a peak in mid-March, and diminishing by September to a few scattered and incomplete songs. Pyrrhuloxias reduce their singing in the latter stages of incubation, but increase it again after the first brood becomes independent. On the wintering grounds Rose-breasted and Black-headed Grosbeaks rarely sing, and *Passerina* buntings are not known to do so.

Time of year may affect not only the frequency but also the structure of cardinal song. In the case of the Northern Cardinal, Ritchison found that the number of syllables per song varied through the season, being significantly higher in February, March, April and again in August. The number of songs per bout was also greater early in the season. Female Northern Cardinals sing less frequently than males, and sing at their peak for a shorter period. Like males, they can and do sing occasionally in any month of the year. In a Kentucky population studied by Ritchison, males began singing in January and continued until late August or early September, while females did not sing until March, reached a

*The **Black-faced Grosbeak** has a broad, deep bill, but can feed on fruits even wider than its gape. Like other cardinalids, it is a "masher" rather than a "gulper", mandibulating fruit in its bill and separating and ejecting seeds and other hard and indigestible parts, rather than trying to swallow the fruit whole. Although largely frugivorous, Black-faced Grosbeaks cannot meet their protein requirements by fruit alone. Fruit-fed captives lose weight if not given additional protein. Caryothraustes grosbeaks are mainly inhabitants of the forest canopy, but the Black-faced Grosbeak will forage at lower levels in more open situations, such as shaded cacao plantations.*

[*Caryothraustes poliogaster poliogaster*, Mexico.
Photo: Roy de Haas/ AGAMI]

*The **Lazuli Bunting** will eat the seeds of wild oats* (Avena) *and other grasses by perching on the stems or reaching from perches on more rigid plants growing among the grasses. It will also reach up from the ground to take the seeds from drooping seedheads and will forage for fallen seeds. Seeds, however, made up only 30% of the plant matter in Lazuli Bunting stomachs in California. Lazuli Buntings also eat substantial amounts of animal matter, especially during spring and summer. Wintering Lazuli Buntings are found in habitat with the same characteristics as their breeding grounds.*

[*Passerina amoena*, USA. Photo: Mike Danzenbaker/ AGAMI]

peak in the weeks just prior to nesting, and were rarely heard to sing after mid-May.

Northern Cardinals begin singing earlier in the day during the breeding season. In the northern USA, A. Leopold and A. E. Enyon noted that cardinals in Wisconsin sang more than an hour before sunrise in late June, particularly when the skies were clear. Rose-breasted Grosbeaks may start to sing as early as 03:00 hours. Both species sing less frequently, if at all, during the midday hours. Indigo Buntings sing from dawn to dusk, reaching a peak in the early-morning hours before sunrise. Lazuli Buntings sing from about one hour before sunrise until 45 minutes after sunset, with a peak in the morning and another at dusk. Varied Buntings sing at any time of day during the breeding season, with no "dawn chorus" or peak singing period. Similarly, at the beginning of the breeding season, when song activity is most intense, male Dickcissels sing throughout the daylight hours, often devoting 50% or more of their time to singing.

Many cardinalids sing from a series of elevated perches, either centrally, near the nest tree, or along the perimeter of the territory. Ultramarine and Crimson-collared Grosbeaks reportedly sing from deep cover in a tree or bush, although an extralimital Crimson-collared Grosbeak in Texas sang from exposed dead limbs and treetops. Painted Buntings prefer to sing from cover until the females arrive, but after that they do more than half of their singing from exposed perches. Dickcissels sing persistently from elevated perches within their territory, repeating their fairly simple songs every 3–8 seconds.

Northern Cardinals use specific song perches more than 10 m above ground, each territory usually having 4–7 such songposts. They will sing also, usually at lower amplitude, from low shrubbery or the ground. Pyrrhuloxias deliver their songs from a number of perches either in the centre or at the edge of their territories. They use the same perches throughout the breeding season, visiting them in a specific order. Varied Buntings do most of their singing from 3–4 exposed perches at the edge of the territory, but they sing from shade if the temperature rises above 37°C. Male Varied Buntings feeding young sing from a standard perch near the nest before delivering food to the nestlings.

A number of species, including the Rose-breasted and Black-headed Grosbeaks, sing from the nest while incubating or brooding. Furthermore, these two grosbeaks will sing during flight displays, and Indigo Buntings may sing during aerial chases with other males.

Among cardinalids, the male's advertising song, as is common in oscines, seems to function in the establishing and maintaining of territory, particularly early in the breeding season. The fine structure of the songs of Indigo Buntings apparently contains a number of cues, including redundant information, that signals the territorial intent of the singer. The placement, spacing and structure of the initial figures in the song may serve to attract attention, while precise details of frequency and spacing may contain specific information enabling other birds to recognize the song as that of a conspecific on territory.

Countersinging and song-matching (replying to a song by giving a similar song) among males is documented for a number of species in the family. Northern Cardinals countersing with neighbouring males, as well as with their mates. As they do so, the number of songs per bout decreases, and the number of syllables per song and the number of syllable types per song increase. Male Pyrrhuloxias in adjacent territories sing either in unison or alternately. Lazuli Buntings sing most vigorously during territorial disputes, and they countersing with neighbouring males throughout the breeding season. Several Varied Bunting males within a canyon may sing at the same time. At times, it appears that one male leads the singing and neighbouring males follow.

Male song may reinforce the pair-bond. The male Lazuli Bunting, for example, sings quietly close to his mate just before egg-laying. With Black-headed Grosbeaks, the territorial function of male song may give way to pair-bond and family maintenance as the breeding season progresses. After egg-laying is complete, males sing mostly in the presence of their mates and are less aggressive towards other males. Once the young have left the nest, the parent Black-headed Grosbeaks sing near their fledglings.

Female song seems to function primarily in reinforcing the pair-bond, rather than in defending the territory, although it may

*Analyses of the stomach contents of the **Painted Bunting** (left) showed that 70–73% of its diet consisted of grass and other seeds. As well as perching on stems, Painted Buntings will use their weight to bring a seedhead to the ground and hold it down with their feet while stripping it with the bill. They generally forage near the ground, but will go much higher during the breeding season. The diet of the **Indigo Bunting** (right) varies over the course of the year, but always includes seeds. On their breeding grounds, Indigo Buntings are likely to be found in openings in wooded areas, but they may winter in grasslands and crop fields. Flocks of hundreds feed in harvested rice fields in Belize.*

[*Passerina ciris pallidior* and *Passerina cyanea*, Port Aransas, Texas, USA. Photo: Rolf Nussbaumer/ naturepl.com]

serve also to advertise to other females that a male is spoken for. In the case of the Black-headed Grosbeak, female song appears to have no territorial role, as neither males nor females respond to playback of the songs of other females of the species, but it is probably important in reinforcing the pair-bond and may serve to maintain the integrity of the family group.

For some species, however, female song may have a territorial role. For example, Skutch heard a female Blue-black Grosbeak sing during a chase involving two or three other birds. Female cardinals may sing in aggressive encounters with other females, and female Pyrrhuloxias, which sing only rarely, may do so while defending the nest. J. Vondrasek found that female, but not male, Northern Cardinals in newly formed pairs sing more often than those in pairs that had previously bred. This may be because new partners establishing a territory are more likely to find themselves in aggressive encounters with others of the species.

With both Black-headed Grosbeaks and Northern Cardinals, females normally sing only when their mates are present. Unlike those of some other species, female Northern Cardinals apparently do not sing to re-establish contact with a mate or to advertise for a new one; females were found not to increase their song rates if the males were experimentally removed. Male Northern Cardinals frequently duet with their mates, joining the female after she starts to sing. Duetting may provide an opportunity for members of a pair to learn each other's repertoires.

Female Rose-breasted Grosbeaks sing while nest-building, incubating, brooding, and relieving their mate at the nest, while female Black-headed Grosbeaks sing at the nest in the presence of the mate, away from the nest in the presence of the mate, and from foliage as they seek food for the fledglings. Skutch observed a Blue-black Grosbeak female that sang while nest-building with her mate, and he noted that incubating females sang in response to their mates while sitting. A study by S. L. Halkin suggests that singing from the nest by the female Northern Cardinal may signal to the male that food is, or is not, needed, so that the brightly coloured male can avoid unnecessary visits that could attract the attention of predators. Males approached the nest most frequently when the female sang, but, if she sang a song matching his own, a male was more likely to stay away.

In addition to normal female song, Ritchison twice heard a male-type song given by female Black-headed Grobeaks, on both occasions when the male was long overdue at the nest. Ritchison has speculated that the females may have been trying to lure their mate to the nest by deceiving him into thinking that an intruding male was in the vicinity. He did not record whether the attempts had been successful.

In a study by W. L. Thompson, Painted and Indigo Buntings reacted strongly to songs of their own species, but very little or not at all to the songs of other *Passerina*. Spacing and frequency range of song elements appeared to be the most important clues in species recognition. Emlen used artificially modified songs to identify the critical features for species identification in the songs of Indigo Buntings. These proved to be the morphology of individual syllables and the duration of the intervals between them. These are among the least variable aspects of song among individuals, and are therefore presumably of greater value in species recognition, as opposed to individual or neighbourhood recognition.

Indigo and Lazuli Buntings outside the zone of range overlap (see Systematics) ignore each other's songs, but within it song distinctiveness of the two species tends to break down. In the zone of overlap, the two species defend territories against each other and each responds aggressively to the song of the other species. M. C. Baker found evidence that syllable structure, rather than timing, is the key feature used by non-sympatric populations to identify their own species' song. This is despite the fact that timing does differ between the two species, in that intervals between dissimilar songs are longer in Indigo Buntings than in Lazuli Buntings. This finding conflicts to some extent with Emlen's results.

Indigo Buntings seem not to discriminate between the songs of individual birds, although a male will be more likely to countersing with another male that sings similar song themes to his own. In some circumstances, a male may react less aggressively to songs of neighbouring birds than to those of strangers. Male Black-headed Grosbeaks, on the other hand, can distinguish songs of neighbouring males from those of strangers, and, presumably because a stranger is more likely to be a challenger

*Depending on the time of the year and the type of food available, the **Indigo Bunting** can be found foraging at any level, searching the ground for seeds, using perches in bushes to reach the seedheads of tall slender plants, exploring fruiting shrubs for berries or hunting for insects high in the canopy. This bird, a vagrant in the Azores, is making opportunistic use of what may be an unfamiliar food plant. The Indigo Bunting originally depended on naturally occurring disturbances in shrublands and forests for its breeding habitat, but now uses primarily human-created habitats. Over a 16-year study in Vermont, the bird made use of logged clearings and adjacent forest but was never seen in nearby undisturbed forest.*

[*Passerina cyanea*, Corvo, Azores. Photo: Rafael Armada]

than a neighbour on his own territory, will respond more strongly to it.

Because Indigo Buntings learn their songs from adjacent territorial males, the songs of individuals in neighbouring territories may be nearly identical. A song neighbourhood can have as many as 22 males sharing a song theme. Although the same song elements can be found throughout the birds' breeding range, specific sequences of three or more elements are more localized. No such sequences were shared between populations 250 km apart.

Similarly, Varied Buntings develop song neighbourhoods, areas in which neighbouring males share either entire songs or shorter sequences of syllables. Painted Buntings were found to share song "figures". Of 129 figures identified in the songs of 93 individuals of this species from Georgia and Florida, only seven were unique to single birds. Painted Buntings farther west in the USA, at the Welder Wildlife Refuge, in Texas, shared song elements, but not whole songs.

D. M. Schook and his colleagues, who examined song-sharing among Dickcissels, found that males in adjacent territories sang similar songs. Song similarity decreased with distance, especially for the somewhat more complex "cissel" element of the song.

Songs of singing male Northern Cardinals tend to resemble, in terms of syllable structure, syllable choice, use of variant syllables, and the organization of syllables into song types, those of other males in the same locality. The territorial fidelity of Northern Cardinals may contribute to the development and persistence of local dialects. The number of syllables shared among cardinal populations diminishes with distance, although some syllables can be heard throughout North America. Of 27 syllables identified in songs in Ontario, nine were shared with cardinals from Ohio but only four with birds from Mexico and British Honduras. Cardinals are more likely to respond to their own dialect than to songs from more distant regions. They may not respond at all, at least on first hearing, to songs from geographically distant populations.

In Panama, Blue-black Grosbeaks living along wide stretches of the Chagres River near Gamboa cannot hear conspecifics on the other side, and the species sings different dialects on each bank. On nearby Barro Colorado Island, a distinctive Blue-black Grosbeak dialect has persisted unchanged since at least 1964.

Some Indigo Bunting song traditions can persist for twenty years or more, across many generations of the species. The larger the number of birds in a song neighbourhood, the more likely it is to persist. This species' song themes do, however, change in the course of time. Local immigration and the deaths of males singing certain song types are partly responsible. Some first-year males modify the song that they learn from a neighbour, by adding, subtracting or modifying a song element. These modifications are, in subsequent years, learnt by new first-year birds, leading over time to gradual shifts in the local dialect. At the Edwin S. George Reserve, in Michigan, about 60% of Indigo Bunting songs were new in each year from 1979 to 1984. Most of these new songs failed to reappear in the following year, and fewer than 20% were copied by another male.

R. B. Payne estimated the half-life for the survival of songs to be 3·8 years. Survival of a song tradition over time is purely cultural. Because the birds do not learn their songs from relatives, and because females show no preference for males singing their father's song type, the persistence of a song type appears not to depend on any selective advantage that it may confer.

Cardinalids produce a wide variety of non-song vocalizations. According to Skutch, both sexes of the Black-faced Grosbeak give a series of 3–4, or sometimes 5–6, "chip" notes which may be a call or a song, but which differ from a more melodious song given only by the males. At least 13 calls are given by adult Lazuli Buntings, the most commonly used being essentially identical in structure to those of Indigo Buntings. Northern Cardinals have a vocabulary of at least 16 different calls. The calls of the last-named species, unlike its songs, appear not to be learnt; individuals raised in isolation have the same call repertoires as those of wild cardinals.

Non-song vocalizations of Northern Cardinals range from the faint sounds made by hatchlings to a variety of calls associated with specific aspects of adult behaviour. Loud "chip" calls may be used when a predator approaches the nest, or at similar moments of excitement. Female cardinals use the "chip" call primarily when approaching or leaving the nest. Males give a

specific piping call during courtship feeding, and females make quiet "twitter" calls, possibly indicating submission, in the presence of their mate. Black-headed Grosbeaks have a "wheet!" call that they use only when taking flight. Young of this species, from a few days prior to fledging and for several weeks afterwards, give a "phee-oo" call when they sight a parent with food or hear it calling or singing. Dickcissels have a special call given on long flights, including migratory flights, that sounds like an electric buzzer.

The female Lazuli Bunting uses two calls to stimulate nestlings to beg. She gives a "took" call if the chicks do not beg when she arrives at the nest, and a "cheek" call if the "took" does not elicit the correct response. The begging calls of young Lazuli Buntings 2–5 days old are variable and non-specific, but by 7–8 days of age each chick within a nest has its own distinctive "signature" call. Male Indigo Buntings give a buzzy "tseep", audible for only a few metres, when approaching a female for copulation. This call, accompanied by song, is apparently necessary to arouse the female (see Breeding).

Although a number of cardinalids can make audible non-vocal sounds, including the whirring noise produced by the wings of a large flock of Dickcissels in flight, there seem to be no examples of specialized or deliberately made non-vocal sounds in the family.

Finally, turning to the two probable non-cardinalid genera *Parkerthraustes* and *Saltator* (see Systematics), the Yellow-shouldered Grosbeak is vocally distinctive. Its thin, lisping song is quite unlike the songs of true cardinalids, but is reminiscent of that of some tanagers. The vocal behaviour of the saltators appears never to have been studied in detail. Some saltators are notably fine singers, a characteristic that has made them, despite their sombre plumage, popular as cagebirds in South America (see Relationship with Man). The voices of the Black-headed, Lesser Antillean and Streaked Saltators, on the other hand, have been described as being harsh, and the call of the Black-headed has been said also to be "raucous". Songs of Greyish Saltator inhabiting dry and relatively open areas in northern South America are less tonal, and have wider bandwidths and higher frequencies, than those from more heavily vegetated habitats elsewhere within the species' range. Female song has been recorded for the Black-headed and Buff-throated Saltators.

Black-throated Saltators, which have a warbling song unlike that of other members of the genus, may sing together as a group during the early hours of the morning. Pairs of Greyish and Buff-throated Saltators sing antiphonal duets. A phrase of three or four syllables given by one individual is replied to with a similar phrase, and the process is repeated many times over. Skutch heard one female Buff-throated Saltator deliver both parts of this duet while approaching her nest. A longer and more powerful song is apparently given by the male alone, either from an elevated song perch or within cover. A rarely heard whisper song, given just before sunrise, is apparently addressed by the male to his mate.

Streaked Saltators generally sing from a lower perch than those preferred by the Buff-throated Saltator. Skutch described a flight display by the former, given at dusk, in which the bird rises in a circling flight to about 30 m into the air, singing loudly, before diving back into the shrubbery. Skutch never observed such a display performed by the three other saltators that he studied, namely the Buff-throated, Black-headed and Greyish Saltators. Black-throated Saltators sing in horizontal flight from one tree to another across the savanna, and Green-winged Saltators likewise sing in flight from tree to tree.

In the upper Térraba Valley, in Costa Rica, both Buff-throated and Streaked Saltators begin singing early in the year. They sing most persistently from the end of March until the beginning of the rainy season, in early June. Buff-throated Saltators also sing actively, mostly at dawn, during July and August, but they rarely do so from September onwards.

The songs of some saltators vary geographically, a fact well known to Brazilian cagebird-fanciers. Skutch noted that Buff-throated Saltator song can vary considerably even between individuals living not many kilometres apart. Moreover, Black-throated Grosbeaks may not recognize the songs of conspecifics that sing in a different dialect.

Food and Feeding

Cardinalids are, by and large, opportunistic omnivores. Plant material, including fruits, flowers, buds, stems, seeds and occasionally nectar, normally represents a higher bulk in the diet than

*The diet of the **Greyish Saltator** appears to vary quite markedly in different parts of its enormous range. Birds studied in Argentina were omnivorous, eating both seeds and insects. But in the* llanos *(seasonally flooded plains) of Venezuela, Greyish Saltators were found to feed almost exclusively on plant tissues, including a wide variety of fruits, leaves, flowers, flower buds, leaf buds, seedpod skins and tendrils from 49 plant species. The Venezuelan birds spent very little time in foraging (5% and 17% of the time in the rainy and dry seasons, respectively) and around 50% of their time was dedicated to resting.*

[*Saltator coerulescens coerulescens*, Mato Grosso, Brazil. Photo: Greg & Yvonne Dean/ WorldWildlifeImages.com]

*The **Black-thighed Grosbeak** usually forages fairly high up in trees, gleaning items from the tips of branches and occasionally descending to middle levels. Although this species appears not to have been previously recorded as eating buds, the congeneric Rose-breasted Grosbeak* (Pheucticus ludovicianus) *is known to take the leaf buds and emerging and young leaves of various trees. Leaf and flower buds can be a seasonally important food for many cardinalids and saltators: in Brazil, flower buds made up almost 37% of the diet of Black-throated Saltators* (Saltator atricollis) *in Minas Gerais.*

[*Pheucticus tibialis*, Monteverde Forest Reserve, Costa Rica. Photo: Michael & Patricia Fogden]

animal matter. Black-backed Grosbeaks near Bogotá, Colombia, have been recorded foraging in the upper levels of arboloco trees (*Polymnia pyramidalis*), taking flowers and seeds and capturing insects from both flowers and the trunk. Northern Cardinals in Florida take nectar on occasion, and Yellow Grosbeaks in Mexico have been recorded as destroying flowers of *Erythrina oliviae* in order to rob them of nectar.

Some cardinalids are primarily arboreal foragers, while others, such as the Northern Cardinal and Painted Bunting, spend considerable time feeding on the ground. Indigo Buntings, Dickcissels and other smaller species take seeds from grasses and herbaceous plants. A single species, for example the Indigo Bunting, may hunt for seeds and insects on the ground, explore fruiting shrubs for berries, and forage for insects high in the canopy.

In a recent worldwide survey of fruit-eating by birds, W. D. Kissling and his colleagues classified the Black-faced, Crimson-collared and Red-and-black Grosbeaks and the Orinocan Saltator as frugivores. Most other cardinalids are at least partially frugivorous; perhaps only the Dickcissel rarely, if ever, eats fruit, although there are no data on frugivory for the Vermilion Cardinal, nor for the Yellow-shouldered Grosbeak and some saltators.

In 1908, W. L. McAtee published a thorough survey of the stomach contents of species of *Cardinalis* and *Pheucticus* native to the USA. For Northern Cardinals, he found wild grape (*Vitis*) to be the most important food item, the birds crushing the seeds as well as devouring the fruit. McAtee found that grape seeds constituted 17% of the Northern Cardinal's diet between November and April. Northern Cardinals in southern Ontario have been observed to crack and eat seeds of the riverbank grape (*Vitis riparia*).

Pyrrhuloxias eat the fruits of the christmasberry cholla (*Opuntia lepticollis*). Rose-breasted Grosbeaks in Pennsylvania are major consumers of elderberry (*Sambucus*) fruits, being second only to Scarlet Tanagers (*Piranga olivacea*) in this respect. Rose-breasted Grosbeaks are almost entirely frugivorous on migration, fruit amounting to 96% by volume of faecal samples taken at an autumn migration site on Block Island, in the US state of Rhode Island, although they take both fruits and insects on their wintering grounds in Costa Rica.

Yellow Grosbeaks observed in Jalisco, in western Mexico, commonly took fruits of the fig *Ficus pertusa* and of the hoop vine (*Trichostigma octandrum*), but visited *Recchia mexicana* more rarely. Both Black-faced and Blue-black Grosbeaks at La Selva Field Station, in Costa Rica, have been noted taking fruits of *Ficus pertusa*. The Black-faced Grosbeak usually ate at least three fruits on each visit, with a mean 3·14 fruits over seven visits during two days, and it may be an important seed-disperser of this species. Fruit, however, appears insufficient to satisfy the protein requirements of these two species; T. C. Moermond and J. S. Denslow found that, unlike birds of purely frugivorous species, captive individuals of these grosbeaks, when fed on a fruit diet, lost weight if they were not given a protein supplement.

Fruit-eating cardinalids, like tanagers and emberizid finches, mash fruits in the bill, separating larger seeds from the pulp and ejecting them before swallowing. Mashing behaviour increases the processing time, but it allows fruit-eating birds to take larger fruits than those which they could comfortably swallow whole, and also avoids the inconvenience of having to carry large, indigestible seeds in the gut. Captive Black-faced Grosbeaks observed by D. J. Levey handled 3–5 small fruits at a time, crushing them for more than a minute and sucking the juices, before ejecting a dry mass of seeds from the bill.

The size and hardness of seeds to some extent determines which ones cardinalids include in their diets. Even the heavy-billed Blue-black Grosbeak cannot handle the hard seeds of *Heliconia*, but both it and the Black-faced Grosbeak can and do crack the smaller seeds of *Psychotria brachiata* (Rubiaceae). The arillate seeds of a number of tropical plants attract cardinalids, as well as other bird species. Black-faced Grosbeaks, for example, eat the large red arils of *Stemmadenia donnell-smithii* (Apocynaceae). Skutch recorded this species feeding on the arils of *Alchornea costaricensis* (Euphorbiaceae), and Blue-black Grosbeaks eating the oil-rich arillate seeds of *Siparuna nicaraguensis* (Monimiaceae), plucking the seeds one by one from the pale red inner surface of the receptacle. Skutch also noted that wintering Rose-breasted Grosbeaks took the arils of five species of Costa Rican plant.

In Middle America, Blue-black Grosbeaks visit multi-crop fields known as "milpas" to feed on crops of maize, as well as

*The **Greyish Saltator** is found in a range of habitats, including forest edge and second growth, dry scrub, and gallery forest. It forages mostly in the upper levels of vegetation. Eating the mature leaves of woody plants is relatively unusual among small passerines, but folivory has been reported for at least seven* Saltator *species. During the dry season in the Marumbi State Park (Paraná), in Brazil, when fruit was hard to come by, leaves from ten species of woody plant accounted for 91% of the food items taken by saltators. Leaves provide poor nutritive value relative to their bulk, which may partly account for the long periods of inactivity noted for Greyish Saltators in Venezuela.*

[*Saltator coerulescens coerulescens*, Corrientes, Argentina. Photo: Darío Podestá]

visiting rice fields in wooded zones. Painted Buntings are primarily ground-foragers and seed-eaters. Analyses of the stomach contents of individuals from Florida and Texas showed that 70–73% of the diet consisted of seeds, including those of grasses and other plants. Lazuli Bunting diets are lower in seeds, which constituted only some 30% of plant matter in stomachs of this species in California.

Northern Cardinals are efficient in digesting seeds, although less so than some emberizid sparrows that specialize on seeds to a greater degree. According to a number of metabolic studies, cardinals are able to extract 75–84% or more of the utilizable energy from sunflower seeds (*Helianthus*), 85% from millet, 84% from sorghum (*Sorghum*), 79% from hemp (*Cannabis*) and 77% from ragweed (*Ambrosia*) seeds.

Cardinalids take varying amounts of animal prey, usually insects and other arthropods but, very occasionally, larger items. A Northern Cardinal, for example, has been seen to eat a field-mouse (Cricetidae). They may increase the proportion of animal prey in the diet during the nesting period. According to McAtee, animal matter normally amounts to some 30% of the diet of Northern Cardinals, but rises to as much as 78% in May, when the birds are nesting. Rose-breasted Grosbeaks also shift from a preponderance of plant material outside the breeding season to a diet of almost 75% animal matter while nesting. In north-eastern Venezuela, 83% of emetic stomach samples taken from Vermilion Cardinals contained the remains of invertebrates, while 48% contained fruits and 84% held seeds.

Blue Grosbeaks at five nests observed by F. J. Alsop in Tennessee fed their nestlings almost exclusively with large mantids (Mantidae) in excess of 75 mm in length, from which the adults had removed the head, wings and most or all of the legs. These insects accounted for more than 96% of items delivered to the chicks. Female grosbeaks, followed by their mates, plucked the mantids from weedy vegetation while in short or hovering flight, or while hopping on the ground.

Indigo and Lazuli Buntings glean insects and spiders (Araneae) from the foliage of trees and shrubs, and Blue Buntings have been seen to peck at spider webs. In Hawaii, introduced Northern Cardinals hunt flying termites (Isoptera) in mid-air. Rose-breasted Grosbeaks are acrobatic feeders, capable of hanging upside-down from the ends of fine branches or pursuing flying insects on the wing. Individuals as young as 47 days have been seen to catch insects in the air. Females of this species hunting insects in New Hampshire foraged higher in trees than males, while males attacked prey on trunks and branches more often than females, a pattern exhibited also, interestingly, by Scarlet Tanagers. Grosbeaks treat animal food much as they do fruits, mashing and tenderizing it in the bill before swallowing.

Yellow Grosbeaks are rare components of mixed foraging flocks in western Mexico. Farther south, on Cerro Pirre, in east Panama, flocks of 6–10 individuals of the localized subspecies *simulans* of the Yellow-green Grosbeak regularly joined canopy flocks of New World warblers, tanagers, foliage-gleaners (Furnariidae) and woodcreepers (Dendrocolaptidae). They also foraged on their own, moving quickly through upper, outer branches, searching bark and foliage. Yellow-green Grosbeaks are common in mixed foraging flocks in Amazonian Brazil. Their congener the Black-faced Grosbeak associates in feeding assemblages that may consist of 30 or more individuals. Moermond has suggested that these large assemblages are the product of several "feeding units", presumably family groups, which join together (see Breeding). They have been recorded searching for arthropods in curled-up dead leaves.

One of the few cardinalids with a considerably higher recorded proportion of animal material than plant matter in the overall diet, in McAtee's analysis 65% as against 34%, is the Black-headed Grosbeak. This species and the Black-backed Oriole (*Icterus abeillei*) are the major avian predators of overwintering monarch butterflies (*Danaus plexippus*) in Mexico. Particularly on cooler days, when the insects are less active, the two bird species attack the butterflies in synchronous waves, acting as a single large mixed flock. L. S. Fink and L. P. Brower showed in experiments that the grosbeaks, unlike the orioles, appear immune to the emetic properties of the butterflies' cardenolide defences. Although the grosbeaks are eventually affected by the cardenolides, they are nonetheless able to consume the butterflies in large numbers, and may take more than the orioles. The birds prefer male butterflies, which have lower

The nectar of the ocotillo (Fouquieria splendens) *provides a seasonally important food source for resident desert species such as the* ***Pyrrhuloxia*** *(above) and a refuelling opportunity for Neotropical migrants such as the* ***Black-headed Grosbeak*** *(below). The blooming of the ocotillo in the Sonoran and Chihuahuan Deserts coincides with the spring passage of a number of hummingbird species (Trochilidae), and the long red tubular flowers appear to be adapted to pollination by hummingbirds. Cardinalids, with their shorter bill, rob the flowers by plucking them, consuming the nectar and discarding the rest of the tough and indigestible flower. In Arizona, 26% of Pyrrhuloxia records come from semi-arid grasslands and Chihuahuan desert scrub that includes ocotillo, acacia* (Acacia), *soaptree yucca* (Yucca elata) *and scattered mesquite* (Prosopis). *A further 38% of records come from Sonoran desert-scrub associations, including saguaro* (Carnegiea), *paloverde and other cacti, and leguminous trees. The Pyrrhuloxia also visits saguaro cacti in bloom for its nectar and pollen.*

Several members of the genus Pheucticus *consume flowers or rob them of their nectar. The* ***Golden-bellied Grosbeak*** *is seen here foraging on the flowers of* Bougainvillea *by plucking them. The closely related Yellow Grosbeak* (Pheucticus chrysopeplus) *takes nectar from the bird-pollinated* Erythrina oliviae *in Mexico, destroying the flowers in the process.* Pheucticus *species have also been recorded as chewing and dropping banana flowers. Black-headed Grosbeaks* (P. melanocephalus) *visit agave flowers for nectar and have also been seen to feed on sugar solution at hummingbird feeders.*

[*Pheucticus chrysogaster chrysogaster*, Jorupe, Ecuador. Photo: Greg & Yvonne Dean/ WorldWildlifeImages.com]

cardenolide levels than females, and they may distinguish the sexes by taste during a preliminary bite. Brower and W. Calvert have suggested that the pattern of synchronous attacks on the butterflies by grosbeaks and orioles may be maintained by cultural transmission from one generation to the next.

Dickcissels studied in Kansas, in the central USA, hunted through lower vegetation in search of insects or seeds, including grains of wheat. Throughout the breeding season they spent 17–21% of their time each day in foraging (see General Habits). Males devoted most of their time to feeding in forbs, where insects, particularly grasshoppers (Orthoptera), were more abundant than they were among grasses. R. L. Schartz and Zimmerman have estimated that Dickcissels need to eat 23 grasshoppers per hour to supply their energy requirements. There may be an increased peak of feeding activity in the evening if the temperature drops below 10–15·5°C, presumably to supply extra energy for temperature regulation during the night.

On the wintering grounds in Venezuela, Dickcissels formerly foraged on native grasslands, but they now gather in often enormous flocks that descend on local rice and sorghum fields, as well as feeding in fallow agricultural fields with abundant wild grasses such as *Rottboellia cochinchinensis* and *Oryza latifolia* (see also Movements, and Status and Conservation). Although Dickcissels may prefer wild grains such as millets (e.g. *Echinochloa*) over cultivated ones, rice and sorghum now make up some 80% of the birds' winter diet. Basili and Temple recorded that the birds fed in the morning and afternoon, but rested during the day. The longest feeding bouts involved feeding on immature green sorghum, one female eating 52 seeds in 241 seconds and the male 80 seeds in just under 290 seconds. Basili and Temple estimated that the 6,450,000 or so Dickcissels wintering in Venezuela eat 4,442,760 kg of rice seeds, 2,300,070 kg of sorghum seeds and 1,677,000 kg of wild grass seeds in the course of a single season, figures that nonetheless amount to no more than between 0·74% and 1·35% of the total crop.

Leaf-eating, folivory, is uncommon among small birds, presumably because of the lower ratio of nutritive value to bulk in a leaf diet. Indigo Buntings in Michigan eat leaves of aspen (*Populus*) and other trees on first arrival in spring, but not later in the season when other foods are more readily available. G. M. Sutton recorded Crimson-collared Grosbeaks in Mexico "munching" leaves of mullein nightshade (*Solanum erianthum*).

Folivory is much better documented for some saltators. Leaf-eating has been reported for Buff-throated and Black-headed Saltators in Costa Rica, Greyish Saltators in Costa Rica and Venezuela, Rufous-bellied Saltators in Bolivia, Masked Saltators in Colombia, Green-winged and Thick-billed Saltators in Brazil, and Orinocan Saltators in Venezuela. Moreover, E. S. Munson and W. D. Robinson have suggested that the Thick-billed Saltator, a primarily Brazilian species, may be an obligate folivore, the only one so far known among the Passeriformes. Leaves from ten species of woody plant, particularly the tree *Piptocarpha angustifolia* (Asteraceae), accounted for 91% of the food items taken by the species in the Marumbi State Park, in Paraná, during August, admittedly at the height of the dry season when fruits, which the birds perhaps eat at other times, are harder to come by. These saltators worked plucked leaves slowly back and forth through the bill, folding them lengthwise and pinching them until they formed small, mashed balls suitable for swallowing. The processing time was 5–26 seconds per leaf.

In the *llanos* of Venezuela, Greyish Saltators were found to feed almost exclusively on plant tissues, including a wide variety of fruits, leaves, flowers, flower buds, leaf buds, seedpod skins and tendrils from 49 plant species. Fruit and mature leaves made up, respectively, 36% and 28% of the diet. The birds defecated the intact seeds of fruits. During the dry season, when deciduous plants lost their leaves, the saltators ate a higher proportion of flowers and seedpod skins. When offered a choice, captives strongly preferred fruits over leaves or flowers, and wild leaves over cultivated leaves.

Leaves and flowers may provide birds with nutrients, such as the elements calcium and phosphorus, that are scarce in fruits. Leaf-eating saltators, unlike larger obligate folivores such as the Hoatzin (*Opisthocomus hoazin*), appear not to retain food in the gut for long enough to ferment plant fibres. They appear to have adopted, instead, a "skimming" strategy, substituting rapid food intake and processing for more efficient digestion. Rodríguez-Ferraro and her colleagues found that captive Greyish Saltators retained leaves in the gut for an average of only 45 minutes, even less time than they did fruits, which were kept in the gut for a

mean of 54 minutes. They found no evidence that the birds could break down cellulose fibres. Presumably, the birds satisfied their energy requirements, to the extent that they were able, from soluble materials in leaf cells. This may not be enough for an active life. Captives spent 50% of their time in resting, and, in a study by C. Bosque and his colleagues, both Greyish and Orinocan Saltators, which have a similar diet but take fewer leaves and a higher proportion of flowers, had lower basal metabolic rates than would be expected for birds of their size.

Saltators in general are mostly frugivorous, although they will also take nectar and may include arthropod prey in their diets. Golden-billed and Greyish Saltators in the Paraná Valley, in Argentina, consume a wide range of foods, with seeds predominating, particularly those of *Solanum amygdalifolium*; they also take insects, primarily leafcutter ants of the genus *Acromyrmex*. The diets of the two species overlap broadly. Both appear to be opportunistic feeders, seasonal shifts in diet by the Golden-billed Saltator being due largely to the high availability of *Solanum* seeds in the austral spring.

Streaked Saltators in Venezuela consume both fruits and seeds of columnar cacti (*Stenocereus*). In Costa Rica, Buff-throated, Black-headed and Greyish Saltators feed primarily on fruits when not breeding, but switch almost exclusively to arthropods when feeding nestlings. Buff-throated and Greyish Saltators also eat the corollas of flowers, and Buff-throated and Streaked Saltators feed on the arillate seeds of a number of Costa Rican plants, including *Protium* (Burseraceae).

Buff-throated Saltators have been seen to eat army ants (Ecitoninae), and ants have been recorded in their stomach contents. This was the third most commonly seen species attending army-ant swarms in Yacambú National Park, in Venezuela, in 2006. Rodríguez-Ferraro observed Greyish Saltators in Venezuela as they caught insects in July and September, when they were feeding chicks and moulting the body and wing feathers. Unusually, a mist-netted Black-headed Saltator in Costa Rica was found to have eaten part of a hummingbird (Trochilidae) adjacent to it in the net.

At least one member of the genus, the Green-winged Saltator, is primarily an insect-eater. This species has been observed while feeding at a swarm of emerging winged termites, and, with Black-throated Grosbeaks, joining mixed-species foraging flocks in Atlantic rainforest. The Green-winged Saltator complements its diet with fruits, and has been seen to swallow fruits of *Eugenia* and *Solanum granuloso-leprosum*, and to glean fruits of *Psychotria brasiliensis* (Rubiaceae), crushing them with the beak turned upwards. Black-throated Saltators studied by C. Gomes de Almeida in Minas Gerais, in Brazil, foraged in small groups of, on average, three individuals, mostly on the ground or in low vegetation. Their diet consisted of 40% seeds, 36·9% flower buds and 13·8% fruit, as well as small numbers of invertebrates.

It has been suggested that the Rufous-bellied Saltator may be dependent on mistletoe berries of the genus *Tristerix*, but this species has been recorded also as taking fruits of a number of other plants, including *Berberis* and *Heteromelas*, as well as insects and seeds. An individual observed in Salta, in Argentina, fed mostly on *Brachyotum* berries, but also consumed young leaves of an introduced willow (*Salix*) and took young grass shoots from the ground.

The Masked Saltator may be a specialist on the cones of *Podocarpus oleifolius* (see Status and Conservation). J. A. Tobias and R. S. R. Williams found this species to be a component of mixed flocks of tanagers and chlorophonias visiting *Podocarpus* stands in the Andes of southern Ecuador. The birds often lingered for long periods in the canopies of podocarps, feeding on the cones, and the observers never saw them take any other kind of food. L. M. Renjifo, who observed what may be a distinct population of the species in Colombia, did record it taking other types of fruit, though in much smaller quantities. When eating

Although primarily a ground-feeder, the ***Orange-breasted Bunting*** *has been recorded as visiting the flowers of the liana* Combretum fruticosum *in a tropical dry forest in south-western Mexico, and is seen here feeding upon the flowers of a similar species. In contrast to the five* Passerina *species occurring in the USA, which are comparatively well studied, little is known of the ecology of the Orange-breasted Bunting and its congener in Mexico, the restricted-range Rose-bellied Bunting* (Passerina rositae). *It is not known, for example, why in Chiapas, in Mexico, the Orange-breasted Bunting occupies only a minor proportion of apparently suitable habitat.*

[*Passerina leclancherii*, Mexico. Photo: Roy de Haas/ AGAMI]

*Throughout the breeding season, the **Dickcissel** spends 17–21% of the time each day in foraging, flitting through lower vegetation in search of seeds and insects. In winter, its diet is more vegetable-based. Although Dickcissels may prefer wild grains, cultivated grains such as rice and sorghum (shown here) now make up some 80% of the birds' winter diet. The longest feeding bouts recorded in a study on the wintering grounds in Venezuela involved feeding on immature green sorghum. One female ate 52 seeds in 241 seconds, and a male 80 seeds in just under 290 seconds. Unlike most other cardinalids, the Dickcissel rarely, if ever, eats fruit.*

[*Spiza americana*, Harlingen, USA. Photo: Daniel Dupont]

Podocarpus cones, which they do at all times of year, the saltators concentrated on the seeds, discarding the fleshy red peduncle that attracted other birds.

The little-known Yellow-shouldered Grosbeak, the sole member of the genus *Parkerthraustes* and, like *Saltator*, probably not closely related to other members of this family (see Systematics), apparently forages as single individuals in the company of other canopy birds. It gleans items from foliage near the ends of branches.

So far as is known, "typical" cardinalids drink in the manner normal for most bird species, scooping up liquid in the bill and tilting the head upwards to swallow. Indigo Buntings drink only infrequently, but Varied Buntings do so occasionally, sometimes in groups, and Lazuli Buntings drink dew and rainwater from vegetation. Saltators are capable of suction-drinking, sucking liquid into the mouth, an ability otherwise unknown in the Cardinalidae, although Rose-breasted Grosbeaks have been seen to make throat movements while the bill is immersed in water. Suction-drinking is documented for many tanagers, among which it may have evolved as an adaptation for eating succulent fruits.

Breeding

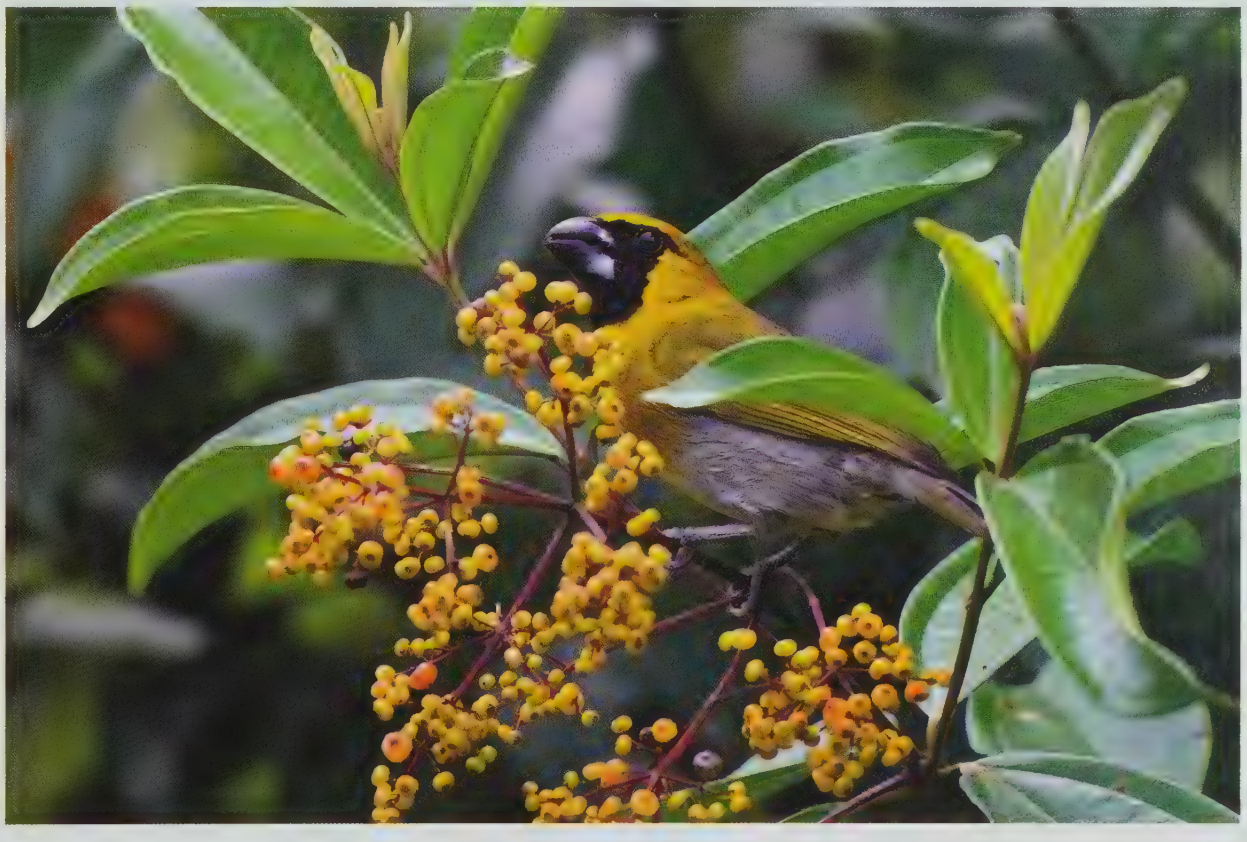
Little information is available on the mating system of Neotropical members of the family. Indeed, the breeding behaviour of the Red-and-black Grosbeak, the sole member of the genus *Periporphyrus*, remains completely unknown. One Neotropical species, the Black-faced Grosbeak, may breed co-operatively, and the same presumably may apply to its congener, the Yellow-green Grosbeak, although the latter's breeding habits have not been studied. Skutch recorded that parent Black-faced Grosbeaks feeding the young were assisted by helpers, and Moermond observed groups of adults attending young in the nest at La Selva, in Costa Rica. Although the groups contained six to eight individuals, only four fed or defended the chicks. Moermond suggested that social organization in this species may consist of a breeding pair with one or two helpers, presumably offspring from earlier broods, accompanied by less closely related "hangers-on".

There is a single record of a Northern Cardinal nest shared by two females, one an albino, both apparently mated to a single male, and one record of a bigamous male in Ohio provisioning two independent nests and successfully fledging young from both. There are also at least two records, including a recent one from Oklahoma, of a single nest being occupied by two females, each mated to a different male. These appear to be incidents of nest-sharing, rather than co-operative breeding, although in the Oklahoma case one male fed all three nestlings.

All North American cardinalids with the exception of the Dickcissel are primarily monogamous, though with varying degrees of polygyny in some species. The Blue-black Grosbeak of Middle and South America, both sexes of which build the nest and feed the young, may likewise be monogamous. There is no evidence of any polygynous behaviour, including extra-pair copulations, by Black-headed Grosbeaks and Varied Buntings. Only 3·7% of male Lazuli Buntings in western Montana had more than one mate at a time, and none changed its mate over the course of the season. Indigo Buntings have been characterized as polygynous, although most males have only one mate per season. At different sites in Michigan, 8·8–19·2% of breeding males had two, or even three or four mates, either simultaneously or in sequence. In Indiana, Indigo Buntings holding higher-quality territories, with high vegetation density and lush ground cover, were more likely to be polygynous. Polygynous males were just as successful at fledging young as monogamous males, suggesting that polygyny, if it can be achieved, confers an advantage. As males take only a limited role in caring for their young, females do just as well in terms of reproductive output when mated to a polygynous male as they do with a monogamous one.

Birds will occasionally mate outside their social pair, and females may settle on territory whether or not the male occupying it is mated. A female Indigo Bunting may make no effort to prevent her partner from mating with another, although the Paynes recorded a case in which, after a new female Indigo Bunting mated with a returning male on his old territory, nested and laid eggs, the female of the previous year arrived and repeatedly chased the new one until she abandoned her nest. After her victory, the old female nested in her turn.

Dickcissels are polygynous, the male mating with up to six females, although males on poorer territories may go without a mate, and a variable proportion of males in a population will have only one partner. The number of females with which a male



The few published data on the food and feeding of the ***Golden-bellied Grosbeak*** *include an analysis of the stomach contents, which found "purplish berries". Here, indeed, the bird is feeding on the purplish berries of the chaquirón tree* (Pithecellobium excelsum). *The Yellow Grosbeak* (Pheucticus chrysopeplus), *sometimes considered conspecific with the Golden-bellied Grosbeak, commonly takes fruits of the fig* Ficus pertusa *and the hoop vine* (Trichostigma octandrum) *in Jalisco, in western Mexico.*

[*Pheucticus chrysogaster chrysogaster*, Chaparri Ecological Reserve, N Peru. Photo: Heinz Plenge]

is likely to mate depends upon the quality of his territory, measured in terms of the number of possible nest-sites that it contains (see Habitat). E. J. Finck found that Dickcissels on prime territory in Kansas spent more time in territorial display than those on less suitable areas, but the amount of time that they put in was not related to the number of females they managed to attract. Instead, the primary purpose of territorial display appears to be defence against other males. Competition for optimal territories appears to be intense. If a territory-holder in Finck's study area disappeared, it was replaced within a couple of days.

Pair-bonds of cardinalids may be short-term arrangements, or, as has been recorded for Northern Cardinals and Varied Buntings, they may be maintained for repeated nesting through the breeding season or even into succeeding years. Northern Cardinals usually join flocks in the winter months, but pair-members in Tennessee remain together and on territory throughout the year.

Fruits eaten by the ***Black-faced Grosbeak*** *include the berries of* Hamelia, *shown here at their pre-ripe yellow stage. Captive Black-faced Grosbeaks were observed to handle 3–5 such small fruits at a time, crushing them for more than a minute and sucking the juices, before ejecting a dry mass of seeds from the bill. Small seeds were usually ingested, but, as seed size increased, the proportion of dropped seeds increased until, at about 4 mm, almost all seeds were dropped. Two cardinalid species, the Black-faced Grosbeak and the Blue Bunting* (Cyanocompsa parellina), *were among the three bird species that between them took 5% of all the fruit from a strangler fig* (Ficus) *in rainforest in Mexico.*

[*Caryothraustes poliogaster*, San Gerardo de Dota, Costa Rica. Photo: Paul Bannick]

Second only to the Scarlet Tanager (Piranga olivacea), *the* ***Rose-breasted Grosbeak*** *is a major consumer of elderberry* (Sambucus) *fruits in the north-eastern United States (Pennsylvania) and adjacent parts of Canada. Red elderberry* (Sambucus racemosa pubens), *typically found in forest gaps, is among the earliest woody plants to fruit in this region and is available to forest birds between mid-June and mid-July, while they are still nesting. Each fruiting plant typically has 20–50 clusters of fruit, with about 200 individual fruits per cluster. The glowing red fruits are small (3–5 mm) and juicy (as can be seen from the explosion of juice from this bird's bill), and have a relatively high energy content of 68·8 kcal/100 g. The fruit is eaten as soon as it ripens, and bushes are often completely depleted within a week to ten days. The Rose-breasted Grosbeak is almost entirely (96% by faecal content) frugivorous on migration, a dramatic shift from a diet that is about 75% insect-based during breeding. A study of migratory birds in Rhode Island, also in the north-eastern USA, found that omnivorous species which shifted their dietary intake to more than one-third fruit put on weight much faster than did those that remained mostly or strictly insectivorous. The extent of frugivory for a species was positively correlated with average change in energetic condition and fat score per day, while insectivorous species on average declined in energetic condition during their stopover.*

[*Pheucticus ludovicianus*, Saint-Lambert, Québec, Canada. Photo: Daniel Dupont]

*For the **Northern Cardinal** in the USA, the wild grape* (Vitis) *is the most important food item during the autumn. The birds continue to eat the grapes so long as any partly dried fruit remains. As their preferred fruit becomes exhausted, however, they turn to others which they previously ignored. In a study in Ohio between 18th September and 12th November 1993, 54% of fruits consumed were wild grapes, 15% rose hips* (Rosa multiflora), *8% honeysuckle* (Lonicera) *and 23% other fruits, including hackberry* (Celtis occidentalis) *and wild cherry* (Prunus serotina).

[*Cardinalis cardinalis cardinalis*, SW Ohio, USA. Photo: Dave Maslowski/ Maslowski Productions]

Partners may leave wintering flocks together, but it is not known whether these are individuals that were mated in the previous season or whether they have paired up over the winter. C. T. Perdue reported Northern Cardinals courtship feeding all year around, and suggested that this might reinforce the pair-bond. However, such behaviour has apparently not been observed by others, and is presumably rare. It is possible that some Painted Buntings pair on their wintering grounds in Costa Rica, as partners have been seen together there. Males usually arrive on the breeding grounds in advance of females, and it seems more likely that most pair formation takes place after arrival.

With Pyrrhuloxias the pair-bond tends to break down in late summer, but pair-members have been seen to be associating with each other in winter and it is possible that some bonds survive to the following season. Indigo Bunting mates separate after the completion of the breeding season, but roughly half of females whose males return in the next spring will reunite with their previous partner. The Paynes have recorded Indigo Bunting partners that bred together for as long as five years, although this may be less a reflection of a long-term pair-bond than of the fact that each member of the pair returned to the same territory. The act of reuniting with an old mate did not improve or reduce a female's nesting success. Some 11% of pairs broke up after the first breeding attempt, after which the female moved to a new territory and nested again with another male. She was more likely to do this if she had been successful in her first attempt, and she sometimes took her first brood with her to the new territory.

Dickcissels pair quickly once a female arrives on a male's territory. Similarly, female Black-headed Grosbeaks may select mates within hours of arriving on the breeding grounds, and it is possible that some pair before arrival, which may also be true for Rose-breasted Grosbeaks. Female Indigo Buntings, on the other hand, have been recorded spending as long as 34 days on a male's territory before completing a nest, suggesting that pair formation can sometimes be protracted. It has been suggested, however, that the birds might simply be postponing nesting because cowbirds are present in the area, or due to poor weather.

Pair-bonding itself is initiated with a series of courtship displays. Those of the Northern Cardinals include song flights in which the male, with the crest raised and the breast feathers fluffed, flies towards the female while singing, and alights near her. Aerial chases may follow. Males and females join in countersinging, and, in later stages, courtship feeding, during which the female assumes a submissive begging posture. Displays may show off carotenoid feather ornaments, including the breast feathers of males and the underwing-coverts of females, in the latter case an ornament that is normally not visible. These include lopsided displays in which the bird twists and angles its body to show off the feathers on its underside, including the underside of the tail, and often lifts the uppermost part of the wing away from the body.

North American cardinalids are particularly aggressive during the early part of the breeding season, when territories are being established. Males frequently chase each other in territorial disputes. Female Rose-breasted and Black-headed Grosbeaks are also aggressive towards one another during the breeding season. Male Lazuli Buntings are especially aggressive towards other males during pair-bonding, and also in the days preceding egg-laying, when females solicit copulation and their mates guard them. Chases can last for ten minutes as males pursue each other, flying through vegetation or spiralling into the air.

Male Dickcissels chase other males that fly across their territory, individuals taking up the pursuit as the flying intruder crosses one territory after another. Chases sometimes lead to physical combat as the birds grapple with each other, pecking at each other's eyes or pulling out feathers. Dickcissels encountering each other at territorial boundaries may drop to the ground and approach each other closely, flank to flank. Encounters end with a "winner" flying to a tall perch, while the "loser" squats in a submissive posture. Black-headed Grosbeaks and Painted Buntings have been recorded fighting to the death with conspecifics. In contrast, there are no documented observations of Varied Buntings fighting one another, although this species will engage in mutual chases.

In addition to chases and fights, cardinalids express their aggression through an array of agonistic displays. These can include wing-flicking, tail-spreading and other actions. Pyrrhuloxias in territorial encounters raise the crest and fluff up the plumage. A simi-

The mostly ground-feeding and seed-eating ***Painted Bunting*** *will eat fruit such as these mulberries* (Morus) *opportunistically. Like other omnivorous migrants, however, Painted Buntings may also increase the proportion of fruit in their diet after breeding, to build up energy reserves for the journey south. Although data on the winter diet are scant, they have been seen to feed on fruits such as figs* (Ficus)*, alongside other Neotropical migrants.*

[*Passerina ciris pallidior*, Galveston County, Texas, USA. Photo: Brian E. Small]

lar display by Northern Cardinals is used for expressing fear or submission. Both Pyrrhuloxias and Northern Cardinals lower the crest before or during proper chases or attacks. Similarly, Rose-breasted Grosbeaks raise and ruffle the crown feathers, but are more likely to flee than to attack when in this posture. At higher intensity, when an attack is more likely, the feathers are sleeked.

During the breeding season, all North American cardinalids establish and defend territories that include both nesting and feeding areas. Whether this is invariably true in Middle and South America is not known, although Black-faced and, possibly, Yellow-green Grosbeaks are apparently not territorial. No cardinalid is known to be territorial outside the breeding season.

Males generally establish their territories early in the breeding season. Northern Cardinals may do so as early as January, and may defend territories for seven months. Male Pyrrhuloxias become aggressive as their winter flocks break up, while females remain sociable for longer. Lazuli Buntings establish their territories within a week of arrival on the breeding grounds, and all available territories are rapidly occupied during the first two weeks of the breeding season. A returning territory-holder will usually evict another male "squatting" on his territory, and young birds are unlikely to gain a territory until one of the older males fails to return. Early-arriving Painted Buntings settling on optimum territories are also likely to be evicted by former territory-holders once they arrive on the breeding grounds.

The measure of territory quality may vary from species to species. In the case of Dickcissels, quality is determined by vegetation profile (see Habitat), whereas for Painted Buntings on St Catherine's Island, in Georgia, the key factor may be the greater abundance of marsh grasshoppers in edge habitats, as opposed to interior-forest sites. In mountain valleys in central New Mexico, the key factor affecting territory quality for Black-headed Grosbeaks appears to be the numbers of Steller's Jays (*Cyanocitta stelleri*) and Western Scrub-jays (*Aphelocoma californica*), the chief predators of grosbeak nests. The highest-quality territories are on the valley floors, where jay density is lower. Yearling grosbeaks left to occupy territories on the valley slopes, which have a high density of nest predators, are unlikely to breed successfully. As they become older, Black-headed Grosbeaks shift from these lower-quality territories to higher-quality sites on the valley floor, and their nesting success improves accordingly (see Morphological Aspects).

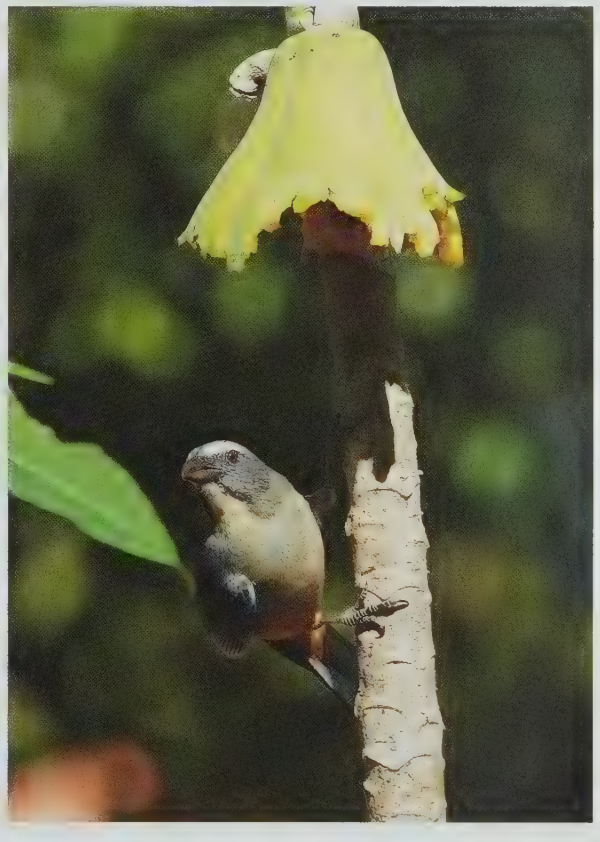
Northern Cardinals, Black-headed Grosbeaks and Lazuli and Painted Buntings are known to return to roughly the same territories year after year. In southern Canada, some Northern Cardinals in London, southern Ontario, remained on the same territory for as long as five or six years. Almost all male Painted Buntings observed on St Catherine's Island returned to the same territory in the following year. In southern Michigan, 95% of older Indigo

The "catkins" of the tropical American tree genus Cecropia *are an important food resource for many avian frugivores. In a study in Espírito Santo state, in Brazil, the* ***Buff-throated Saltator*** *made repeated visits to feed on* Cecropia*, both alone and in company with such other bird species as tanagers (Thraupidae). Buff-throated Saltators are frequently found in mixed-species feeding flocks, sometimes alongside Black-winged Saltators* (Saltator atripennis)*. In Costa Rica, Buff-throated Saltators feed primarily on fruits when not breeding, but switch almost exclusively to arthropods when feeding nestlings.*

[*Saltator maximus maximus*, Podocarpus National Park, SE Ecuador. Photo: Glenn Bartley]

The fruits of wild and cultivated palms can be an important food for frugivorous birds such as this ***Black-winged Saltator****. Because of their habit of mandibulating fruit and ejecting any seeds before swallowing the pulp, cardinalids are generally poor seed-dispersers. The Lesser Antillean Saltator* (Saltator albicollis)*, however, plays at least an indirect role in the dispersal of the buccaneer palm* (Pseudophoenix sargentii) *on the island of Dominica. The saltators take the cherry-like fruits to regular feeding perches, where they discard all but the pulp. But although bits of broken pericarp are found below the perches, seeds are rarely found, and it is thought that rats, lizards or crabs carry them away.*

[*Saltator atripennis*, Cali, Valle del Cauca, Colombia. Photo: Roland Seitre]



Buntings return to the same territory in successive years, but nearly half of those returning after their yearling season shift to a new territory. Yearling males, but not females, are more likely to disperse if they fail in their nesting attempts in their first season, but whether an individual remains on its old territory year after year or shifts to a new one seems to have little to do with its lifetime nesting success.

Female Dickcissels are not philopatric. On the other hand, of a population of males studied over a five-year period in Kansas, an average of 49% returned to the same territory in the following year. Dickcissels are polygynous, and males that had had fewer mates and fledged fewer young were more likely to switch territory than more successful males.

Male cardinalids tend to direct their aggression towards other males of the species, although a male Varied Bunting may tolerate yearlings on its territory even if they are singing, attacking them only if they approach his mate. Similarly, female Northern Cardinals, Rose-breasted and Black-headed Grosbeaks and Lazuli Buntings are territorially aggressive towards other females. Compared with many passerines, both male and female cardinals are relatively high in testosterone levels throughout the year, and this may have some bearing on their territorial aggressiveness. Rose-breasted Grosbeak females are aggressive towards conspecifics of both sexes, although male–female encounters are more frequent than female–female ones, and agonistic behaviour drops sharply after egg-laying begins. Female Pyrrhuloxias become defensive only if their eggs or nestlings are threatened.

Territory size varies a good deal, but for most species it tends to be, on average, roughly 1–1·5 ha. The size can differ considerably even within a species, depending upon such factors as territory quality and male density. In general, territories tend to be smallest in the optimum areas, either because size is limited by competition from other males or because a smaller size can satisfy food and nesting requirements. Painted Bunting territories in Missouri had an average size of 1·44 ha if they were bordered by territories of other males, but isolated males held territories covering on average of 3·92 ha. In Texas, Pyrrhuloxia territories were smallest in areas where there were no Northern Cardinals, and were largest where Pyrrhuloxias were outnumbered by their congener.

Dickcissel territories in Kansas varied in size from week to week and over successive years. The average weekly territory size was 1·76 acres (0·7 ha) in 1966 and 1·25 acres (0·5 ha) in 1967. With this species, territory size depends on the density of males, which is, in turn, governed by the structure of the vegetation. Mated males have larger territories than bachelors. In the central Platte River Valley, in adjacent Nebraska, Dickcissels begin nesting 2–3 weeks after Red-winged Blackbirds (*Agelaius phoeniceus*),

The ***Greyish Saltator*** *can survive on leaves through periods of low fruit availability, but over the year the bulk of its diet is thought to be fruit, in this case a papaya* (Carica)*. Saltators readily adapt to cages and maintain their body mass on a diet of fruit, which they prefer over leaves when offered the choice. When fed on banana mash, they have a fast rate of food passage and a relatively low digestive efficiency, which is compensated for by a high rate of food intake of up to 1·4 times their body mass. Greyish Saltators will come to gardens to eat cultivated beans and tomatoes.*

[*Saltator coerulescens coerulescens*, Pantanal, Mato Grosso, Brazil. Photo: Cassiano Zaparoli]

and male blackbirds often chase male Dickcissels from their territories. The Dickcissel's territorial defence diminishes as the season progresses. Males, particularly less successful ones, spend less time on their territories, an average of 7·5 weeks for males that subsequently switched territories, compared with 10·3 weeks for presumably successful males that returned to the same territory in the following season. Males may even abandon their territories before their females have completed their nesting duties.

Male Dickcissels periodically engage in flights away from their territories, particularly early in the breeding season. These distant flights may allow the birds to assess the numbers of males and the suitability of habitat in other areas (see Habitat). Unmated males will often abandon their territories and seek areas more likely to attract females; bachelor Dickcissels in Kansas usually remained on territory for less than two weeks.

Courtship feeding is uncommon among Rose-breasted Grosbeaks. Both this species and the Black-headed Grosbeak perform song flights that expose the black-and-white wing and tail feathers and the colourful wing-linings. H. R. Ivor documented a courtship dance of "indescribable beauty" by a captive Rose-breasted Grosbeak in which the male crouched on the floor of his cage, spread and quivered his wings, and sang with his head held tilted against the feathers of his back. The grosbeak followed this performance by lunging at the female and seizing her primaries, and copulation soon followed.

Dickcissels engage in sexual chases that end on the ground, where the male makes physical contact with the female and may pull her feathers. Male Painted Buntings, in addition to fluttering flight displays, display on the ground in a flattened posture, with wings and tail spread as they circle the female. Buntings performing this display reminded A. Sprunt of a "miniature turkey gobbler". Indigo Buntings sometimes perform a similar display. The male Indigo Buntings seldom sings during courtship, but he stays close to his prospective mate, chasing off other birds. At times he may force copulation on the female. A female Indigo Bunting will not solicit copulation unless she is in sight of a male, which must both sing and give the "tseep" call (see Voice). She will reply with a similar soft call, and the two will exchange further soft calls before mating.

The role that the bright male plumage of many cardinalids plays in female mate choice varies with species. For some, such as the Northern Cardinal, plumage has a direct role in mate selection. For others, including the Lazuli Bunting and the Dickcissel, quality of territory appears to be the deciding factor. E. Greene and his colleagues found that female Lazuli Buntings in Montana selected males on the basis of territory quality, rather than plumage brightness, preferring territories with high levels of shrub cover. Males holding these territories could be either very bright in plumage or very dull, and included yearling males able to settle in high-quality territories because they were tolerated by adults. Intermediate individuals had more difficulty in gaining good territories, and females were less likely to select them.

In terms of importance in mate attraction, the distinction between ornament and territory may not be clear-cut. Female Indigo Buntings appear to mate at random with regard to the genetic make-up of available males, and show no preference in respect of male song type (see Voice). Redder male Northern Cardinals may in themselves be more attractive to females, but they are also more likely to gain better territories as measured by vegetation density. Black-headed Grosbeak females apparently compete with other females for choice of territory, but active courtship by the male suggests that some direct choice of a mate may be involved.

The brilliant colour of male Northern Cardinals is unusual for a bird that is almost completely monogamous. Jawor and her colleagues have established, on the basis of intensity of red colour in a number of plumage ornaments and in the bill, that Northern Cardinals of both sexes mate assortatively, contradicting the results of an earlier study. Male cardinals, for example, prefer females with a brighter red bill and underwing-coverts. Each sex probably prefers more brightly coloured mates, although it is possible that duller birds may be choosing similar mates by preference, rather than being left with less suitable partners after the brighter birds have paired off.

Different ornaments possessed by cardinals may be correlated with, and thereby signal, different traits, and birds may be assessing several ornaments for various types of information before selecting a mate. Overall brightness, for example, correlates with body size, and bill colour with condition. Individuals with higher carotenoid loads have a better immune system—higher heterophil-to-lymphocyte ratios in males, and higher white

*The **Lesser Antillean Saltator** appears to eat less animal food than the Streaked Saltator* (Saltator striatipectus)*, with which it was considered conspecific until 1993. It brings its nestlings insects only rarely. It inhabits a very wide range of habitats on Guadeloupe and Dominica, Martinique and St Lucia, the four islands on which it is endemic. This species is significantly larger (39·8–51·6 g on St Lucia and reportedly up to 52 g on Guadeloupe) than the Streaked Saltator on Trinidad (30–44 g), perhaps partly because of differences in the frugivore communities of these islands.*

[*Saltator albicollis albicollis*,
St Lucia.

Largely vegetarian on migration and in winter, the ***Dickcissel*** *is omnivorous while breeding, its diet then typically about two-thirds insects and other arthropods, and one third grass and cereal grains. It has been estimated that adult Dickcissels need to eat 23 grasshoppers (Orthoptera) per hour to supply their energy requirements. A study in the early part of the 20th century found that 44 Dickcissel stomachs, collected during May–August in Kansas, Minnesota, Wisconsin and Texas, USA, contained 70% animal and 30% vegetable matter. However, the ratio was reversed in the stomachs of 19 birds from near Atwood, in Illinois, in August, which contained 68% vegetable matter and 32% animal food. All but four of the Illinois birds were the young of that year, and the author of the study suggested that the inexperienced birds were not yet so adept as their parents at finding or capturing insects, whereas seeds were abundant at that time of year. A large proportion of the animal material consisted of grasshoppers, and at least traces of grasshoppers were found in all stomachs. During the first few days after hatching, Dickcissel nestlings were fed large quantities of butterfly and moth (Lepidoptera) larvae and soft-bodied insects, which were rarely found in the stomachs of adult Dickcissel. But from the fifth day onwards, the food brought to the nest consisted almost entirely of grasshopper nymphs and adults.*

[*Spiza americana*, E Nebraska, USA. Photo: Dave Maslowski/ Maslowski Productions]

*Like most true cardinalids, the **Indigo Bunting** eats much more animal matter during the breeding season, including insects and their larvae, and spiders, which it gleans from the foliage of trees and shrubs. The male Indigo Bunting is thought to forage higher in trees than the female. This sexual segregation may be reflected at a geographical scale on the wintering grounds. Male Indigo Buntings are commoner than females farther to the south in Mexico, a reversal of the typical pattern for Neotropical migrants, which are sexually segregated on their wintering grounds, where males generally predominate farther to the north.*

blood-cell counts in females—possibly as a response to increased stress levels arising from aggressive encounters and increased parental care. Males with a brighter breast colour are better at provisioning young, as are females with brighter underwing-coverts. Even so, females pairing with brighter males feed the young less, presumably because the mate is doing a greater share of the work.

Cardinals continue to display their ornaments to each other even after pair formation. Partners may divorce both within the season and during the winter, so displays that reinforce existing pair-bonds may be important, especially as the birds nest repeatedly during the season. The female's underwing displays, which are performed away from the nest, may serve this purpose.

Females of blue-plumaged cardinalids may not rely directly on the structural blue and UV colours of males when selecting mates. B. Ballentine and Hill found that the intensity of male structural colours made little difference to female Blue Grosbeaks. Colour intensity may matter, however, in competition among males for better territories. Brighter male Blue Grosbeaks tend to be larger, and to have larger and higher-quality territories, but they are not necessarily better at feeding young—although they tend to feed first-brood nestlings at higher rates—suggesting that the qualities linked to colour intensity have more to do with competition among males than with parental ability. Bluer males, in addition to gaining better territories with greater food resources, are less likely to be cuckolded than duller individuals. Although females with duller mates might be seeking extra-pair copulations with brighter birds, it is still not clear if structural colours are, in fact, true indicators of male quality.

Extra-pair copulations and the chief response to them, mate-guarding by the male, have been recorded for the Northern Cardinal, the Blue Grosbeak, and the Indigo, Lazuli and Painted Buntings. Despite lengthy observation they have never been seen in the Black-headed Grosbeak, and Varied Bunting partners are so rarely out of each other's sight that such behaviour seems unlikely.

The frequency of extra-pair copulations among Northern Cardinals is lower than that found for many other songbirds, producing 13·5% of nestlings in a Kentucky study by Ritchison. One reason for this may be vigilant mate-guarding by the male. Males maintained contact with their mates an average of 72·8% of the time during initial nesting attempts, and usually followed the female if she flew off. In one of the pairs that did raise an extra-pair nestling, the male spent only 19·4% of his time with the female. Both male and female Northern Cardinals make forays from the territory, presumably in search of extra-pair copulations, although it is possible that they may be seeking food or nesting material, and extra-pair young have been found in 14% of cardinal nests. Female cardinals provided with extra food actually made more trips off-territory than unsupplemented females, supporting the hypothesis that extra-pair copulations, rather than foraging opportunities, may be the goal of such excursions.

In an Alabama study by L. K. Estep and her colleagues, 53% of Blue Grosbeak nestlings were sired by an extra-pair male, and at least 70% of nests had at least one extra-pair chick. The intensity with which males guarded their mates depended on the brilliance, and presumably the attractiveness, of surrounding males, though it may be that straying females were attracted by the food supply on the other males' territories, rather than by their plumage. A similar situation prevails with Lazuli Buntings. The tolerating of dull males has its benefits for brighter birds; the females of the former are available for extra-pair copulations, and their presence in nearby territories serves as a "paternity buffer" against other bright males seeking extra-pair copulations themselves. In Greene's study of Lazuli Buntings, 49% of nests contained at least one chick not sired by the resident male.

Morphometric studies suggest that about 40% of the offspring of Indigo Buntings in Michigan were sired by a male other than the territorial resident, although only 2% of observed copulations were extra-pair. D. F. Westneat found through genetic examination that 14·4% of Michigan offspring had genotypes incompatible with one of their putative parents. In a later study in North Carolina, using DNA fingerprinting, he found that 35% of all nestlings came from extra-pair copulations, and that 48% of broods had at least one extra-pair offspring. In a few cases, the entire brood appeared to have been sired by another male. Westneat also found that males attempting extra-pair copulations were often unsuccessful, failing to make cloacal contact with the female, usually because the female resisted. Females were more likely to resist extra-pair mating attempts than to resist

*Animal food forms a very small part of the diet of the **Black-throated Saltator**. It is probably taken opportunistically as the bird forages on the ground and through the shrub layer in dry grassland and scrub (*caatinga *and* cerrado*) habitats in Brazil, Bolivia and Paraguay. An individual was seen carrying a caterpillar in its beak during the breeding season, but this was assumed to be for the nestlings. Over the course of the year, the main items in the Black-throated Saltator's diet are seeds (40%), buds (37%) and fruit. Its behaviour is quite different from that of other members of the genus in which it is currently placed. It forages both in single-species flocks of up to seven birds and in mixed flocks. One bird is almost always perched in a bush or tree, constantly turning its head from side to side and presumably watching for predators. If a raptor appears, the sentinel calls and the entire flock, including the other species in a mixed flock, flees to cover. Groups of Black-throated Saltators are thought to be families. Parents are helped at the nest by non-breeding birds (presumably earlier offspring), and sentinel behaviour may be related to co-operative protection of the offspring at the nest.*

*The **Indigo Bunting** (top left) and the **Painted Bunting** are regular visitors to feeding stations for white millet and other seeds. They also forage on the ground below the feeders for seeds spilled by other birds. Data from visits to backyard feeders are being used to monitor the population of the eastern race of the Painted Bunting in South Carolina. In many parts of its range, a substantial proportion of the diet of the Northern Cardinal* (Cardinalis cardinalis) *comes from artificial feeding stations, doubtless explaining the high population densities in suburbs. Rose-breasted Grosbeaks* (Pheucticus ludovicianus) *are also regular visitors to feeders.*

[*Passerina ciris ciris* and *Passerina cyanea*, S Florida, USA. Photo: Dave Maslowski/ Maslowski Productions]

copulations with their mates. The male Indigo Bunting does not guard his mate as vigilantly as the Northern Cardinal, but he may be more likely to copulate with her if an intruder is present.

Copulation by cardinalids appears to be typical of passerines in general. Reverse mounting, in which the female mounts the back of the male, has been recorded for a pair of Painted Buntings, the male in that case having been a yearling. Ivor's captive male Rose-breasted Grosbeak was also mounted by the female, but only after copulation. Although birds may copulate at various times throughout the breeding season, effective insemination by Northern Cardinals and Rose-breasted Grosbeaks may happen only during short periods prior to egg-laying. Indigo Buntings, with their more variable mating systems, appear to be capable of inseminating females for longer and more irregular periods.

Most north-temperate cardinalids begin nesting in early spring. In some areas Northern Cardinals may start as early as late February, while Rose-breasted Grosbeaks usually wait until mid-May. In the American Southwest, the laying of the first egg by Varied Buntings coincides with the first significant summer rainstorm. Blue Grosbeaks in the same region may delay the onset of breeding until the monsoonal summer rains, although farther south, in Costa Rica, females have been seen to gather nesting material in May, June and July.

In Costa Rica, the Blue-black Grosbeak reaches the peak of its breeding season in July and August, when the maize crops ripen. As with many other tropical birds, however, the nesting season may be protracted and can vary from place to place. In Colombia Blue-black Grosbeak nests have been found as early as February and as late as October, and in Brazil they have been discovered in March and April. The Glaucous-blue Grosbeak, in common with many south-temperate species, breeds between October and December in Uruguay. Black-backed Grosbeaks have been found nesting in November in Colombia, and Golden-bellied Grosbeaks in arid regions in western Ecuador nest during the rainy season, between February and May.

Some, but not all, members of the family are multiple-brooded. Northern Cardinals may begin a second brood as early as 13–14 days after the first brood fledges if no more than one young from the first attempt survives, but they will wait for an average of 19 days otherwise. Late clutches of this species can be very late indeed; in West Virginia, an active nest was found on 19th October. Pyrrhuloxias apparently do not raise a second brood, or they are rarely successful if they try, although a female has been seen while feeding fledged young as late as October. Vermilion Cardinals and Rose-breasted, Black-headed and Golden-bellied Grosbeaks are usually single-brooded, but in one Michigan case a pair of Rose-breasted Grosbeaks began a second clutch when the young of the first brood were only 2–6 days old.

Blue-black Grosbeaks may raise two or three broods in a season. Second broods are apparently common among Lazuli Buntings and Blue Grosbeaks, at least in the southern portions of their ranges. Varied Buntings, however, will normally renest only if their first breeding attempt fails before the eggs hatch. Dickcissels may renest if they lose their first brood, but usually they do not have enough time to rear a second before the autumn migration. There is a possibility that some very early nesters in the southern part of the Dickcissel's breeding range may move north and nest again later in the season.

Females of both the Indigo Bunting and the Lazuli Bunting normally take sole responsibility for nest-site selection and nest-building. Among other cardinalids, both sexes may help to select the nest-site or, as with Dickcissels, the female does so, her mate accompanying her. A female Northern Cardinal may visit a variety of locations, fluffing her feathers and turning around if she finds a possible site. The male follows her, and the two call to each other and, using the bill, manipulate nesting material. A female Indigo Bunting will often visit several sites before settling on one. She shows no apparent preference in subsequent nesting attempts for the plant species used for a previous successful brood. Instead, her selection appears to be based on such factors as the extent of canopy cover over the nest-site and the rigidity of the supporting stems.

Members of a pair of Rose-breasted Grosbeaks may turn around several times in an appropriate fork, as if testing its suitability as a nest-site. Pairs of Painted Buntings will investigate clumps of Spanish moss (*Tillandsia usneoides*) or other dense vegetation, searching through the foliage more rapidly than they

*Typical cardinalids such as the **Black-headed Grosbeak** drink by dipping the slightly open bill to scoop up water, then tilting the head back to swallow it. "Suction" drinking is not known for these species, though the Rose-breasted Grosbeak* (Pheucticus ludovicianus) *has been seen to make throat movements while the bill is immersed, as well as after the head is raised and tipped back. Rose-breasted Grosbeaks often wipe the bill after drinking, and drinking may precede bathing as a bird enters the water.*

[*Pheucticus melanocephalus*, Agua Caliente, California, USA. Photo: Rob Curtis/ The Early Birder]

Living in arid brushland habitats, the ***Pyrrhuloxia*** *seems to obtain most of its water needs from its food. However, it will drink water when available. Bird species of arid environments tend to have lower total evaporative water-loss rates (TEWL) than birds of wetter habitats, at least when tested in the laboratory. By storing heat in their body tissues during the hottest part of the day, and releasing it when ambient temperatures are lower, these birds can reduce the need for evaporative cooling. It has been estimated that the Pyrrhuloxia, by increasing its body temperature by 2·3°C at ambient temperatures of 38°C, can reduce its TEWL by 50%. Varied Buntings* (Passerina versicolor)*, another species often found in arid environments, including scrub and thorn-forest, have been seen to drink occasionally, sometimes in groups. On migration, Black-headed Grosbeaks* (Pheucticus melanocephalus) *(previous photo) have been seen to drink water at desert springs in California even when edible green vegetation is available.*

[*Cardinalis sinuatus sinuatus*, Rio Grande Valley, Texas, USA. Photo: Derrick Hamrick/ ImageBroker/FLPA]

*The male **Northern Cardinal** gives a specific piping call during courtship feeding, while the female makes quiet "twitter" calls and assumes a submissive begging posture. The courtship displays of the Northern Cardinal include song flights in which the male, with his crest raised and breast feathers fluffed, flies towards the female and alights near her. The displaying birds twist and angle the body to show off their feather ornaments, such as the breast feathers of the male and the red underwing-coverts of the female, which are normally not visible. The redness of the female's underwing feathers is correlated with body size, body condition, date of first nest produced and reproductive success. For the males, however, while redness of the breast plumage positively predicts body size, it negatively predicts nestling-feeding rate. Birds with a smaller black face mask, indicating lower levels of aggression, have greater reproductive success. Cardinals continue to display their ornaments to each other even after pair formation. Because partners may divorce both within the season and during the winter, displays that reinforce existing pair-bonds may be important, especially as the birds nest repeatedly during the season. The female's underwing displays, which are performed away from the nest, may serve this purpose. Northern Cardinals have also been observed courtship-feeding throughout the year. Pair-bonds of cardinalids are often short-term arrangements, but in Northern Cardinals they may be maintained for repeated nesting through the breeding season or even into succeeding years.*

In the Indigo Bunting (Passerina cyanea) *and the Lazuli Bunting* (P. amoena), *the female normally takes sole responsibility for nest-site selection as well as nest-building. But paired* ***Painted Buntings*** *will investigate suitable sites in dense vegetation together, and the male—though less often than the female—may indicate a suitable site by crouching. The site is usually 0·3–2·5 m up in low vegetation, though it can be up to 15 m above ground. The nest, a neat, deep, thin-walled cup, is built entirely by the female from grasses, fine weed stems and similar materials, occasionally incorporating artificial matter such as tissue paper, and bound together by cobweb. She starts it within a few days of finding the site and often completes it in two days.*

[*Passerina ciris*, SE USA. Photo: Roger Givens/DRK]

do while foraging. When they locate a potentially suitable spot, either the female or, in 12 out of 32 observed cases, the male enters the vegetation and crouches. The female may arrange nearby foliage around herself.

Nest-sites are usually at low to medium heights among dense vegetation, usually under some sort of cover, although the only known nest of the Yellow-green Grosbeak was placed 7 m up, and in Canada the average height of 50 Rose-breasted Grosbeak nests near London, in Ontario, was 6 m. Cover may be essential for both concealment and thermoregulation. For Black-headed Grosbeaks, a primary concern in site selection may be that of keeping the nest sufficiently cool. Northern Cardinal nests can be as low as 0·25 m from the ground or as high as 12 m, the height above ground increasing over the course of the breeding season. In western Montana, 95% of Lazuli Bunting nests were within 1 m of the ground, with the remaining nests no more than 2 m up, although some nests of this species have been as much as 8 m up. Indigo Bunting nests are frequently less than a metre from the ground; six nests followed in Michigan, for example, were at an average height of roughly 50 cm. Forty-five Painted Bunting nests found by D. F. Parmelee in Oklahoma were placed 0·3 m to 2·3 m above the ground, at an average height of almost 1 m. As with the Northern Cardinal, nests found late in the season were often higher up than those found earlier.

Dickcissel nests are often placed near the ground, usually in dense vegetation in grasses, forbs or low woody plants with nearly complete overhead cover. Ninety-four nests found by T. G. Overmire in Oklahoma were at heights ranging from 8 cm to 4·25 m, measured from the ground to the top of the nest. The average height of 20 nests on the Arkansas Grand Prairie, where the birds optimally nested in briar patches bordering maturing oat fields, was approximately 1 m. A recent study by J. W. Walk and his colleagues of 505 Dickcissel nests in Illinois grasslands suggests that the birds will nest close to cropland, but may avoid nesting in areas of grassland close to a woodland edge.

Vermilion Cardinals may place their nests in a shrub or a prickly pear cactus (*Opuntia*). The Black-faced Grosbeak apparently conceals its nest among arboreal epiphytes. The Blue-black Grosbeak frequently builds its nest among low forest palms armed with a formidable array of spines. One such nest found by Skutch had been built on the remains of the nest of a Thrush-like Mourner (*Schiffornis turdina*), which had itself apparently been built over another grosbeak nest.

Subsequent broods are normally raised in a new nest, although a pair of Rose-breasted Grosbeaks used the same nest two years in succession, and there are, incidentally, two records of a Rose-breasted Grosbeak nest in Ontario being reused by a Wood Thrush (*Hylocichla mustelina*). Painted Buntings will sometimes reuse an old nest. Although Indigo Buntings rarely do so, one nest of this species was built by the constructing of additional layers over an older one. Lazuli Buntings have not been recorded reusing a nest, but females may return to the same bush, and occasionally the same location within it, as that selected in the previous year. Sutton described an active Dickcissel nest that had been built on top of a failed nest used earlier in the season.

Both sexes of the Blue-black Grosbeak take part in the building process, bringing nesting material and sitting in the nest to give it shape. Both sing as they build. Both the male and the female of the Rose-breasted Grosbeak build, whereas the female of the Black-headed Grosbeak does most of the work of nest construction. With most members of the family, the female builds a nest either alone or, as in the case of the Northern Cardinal and perhaps the Blue Grosbeak, with only limited contributions from the male. The male may accompany his mate during the process, but he is more likely to stay nearby and sing as she proceeds. The nest of the Black-faced Grosbeak is built by both partners, although the female appears to take the major role. J. K. Strecker reported in 1893 that both sexes of the Painted Bunting take part in nest-building, but more recent observers state that the female builds alone.

Northern Cardinals and Black-headed Grosbeaks carry out most of the nest-building work in the early hours of the morning, but female Lazuli Buntings build at any time of day. Female Painted Buntings in Oklahoma engaged in nest-building after

*The female **Black-headed Grosbeak** apparently competes with other females for choice of territory, but active courtship by the male suggests that some direct choice of a mate may also be involved. The pair-bond is formed rapidly, often on the day of the female's appearance on the territory. The nest is built almost entirely by the female. As can be seen here, it is an untidy affair, a loose cup made from slender twigs, plant stems and rootlets. Sites are on average 3–4 m above the ground, usually (though not here) in the outer branches of a small deciduous tree, pinyon pine* (Pinus) *or juniper* (Juniperus). *The nest is lined with finer plant material and hair.*

[*Pheucticus melanocephalus maculatus*, Modoc, California, USA. Photo: Alex Navarro]

sunrise and sunset, but those attending an earlier brood while at the same time constructing a second nest built at sporadic intervals throughout the day. Dickcissel males may interrupt their nest-building mates for bouts of courtship and copulation.

The building of the first nest of the season can take much longer than the time required for subsequent ones. Northern Cardinals may spend 2–3 weeks on their first nest. Lazuli Buntings may take 5–7 days to build a nest early in the season, but they can complete a later nest in as few as two. A female Dickcissel will begin the construction of a number of tentative nests after she arrives on the breeding grounds, but she soon focuses on a single site and completes the building work in about 2–4 days.

So far as is known, all members of the family build open cup-nests. There is, however, a single record of a Blue Grosbeak pair in Arkansas that nested, apparently successfully, in an enclosed nestbox designed for Eastern Bluebirds (*Sialia sialis*). Nests are constructed from twigs, grasses or plant fibres, and lined with finer material. A Black-headed Grosbeak has been observed to steal material from a recently deserted nest of a Brewer's Blackbird (*Euphagus cyanocephalus*). Indigo Buntings bind the nesting materials in place by weaving and wrapping them with spider web, especially around the rim, and incorporate dead leaves into the nest structure. Indigo Buntings and Blue Grosbeaks tend to include pieces of paper, shed snakeskin and similar items, and Blue Grosbeak nests frequently contain pieces of cellophane, perhaps incorporated as a substitute for snakeskin.

Northern Cardinals and Pyrrhuloxias do not attach the nest to the surrounding branches, but simply wedge it into place. *Passerina* buntings anchor their nests in place by weaving strips of grass or bark around supporting twigs. Dickcissels either do not bind their nests to surrounding vegetation or make only a flimsy linkage, relying instead on a number of supporting plants to hold the nest.

The nests of Rose-breasted Grosbeaks can be so sparsely built that the eggs can be seen through the base from below, but they may contain slender forked stems of plants such as white avens (*Geum canadense*) to provide structural strength without adding bulk. The Black-faced Grosbeak's nest is a flimsy structure, with an unusual lining of green bromeliad leaves. Blue-black Grosbeaks may line the nest with black fungal filaments, while Varied Buntings in Arizona line the nest with reddish-brown to yellow stems and the inflorescences of littleseed muhly (*Muhlenbergia microsperma*). They may delay nesting until there has been enough rainfall to allow suitable plants to grow.

Nests can become infested with mites (Acarina) and other invertebrates. Northern Cardinal nests in Ontario each yielded hundreds or even thousands of mites, mostly *Ornithonyssus sylviarum*, as well as spiders, bark lice (Psocoptera) and insects of various sorts. A springtail, *Entomobrya assuta*, may have a particular affinity for cardinal nests.

Egg-laying begins only a few days after the nest has been completed, fewer than six days later in the case of Pyrrhuloxias but after only a day or two in Dickcissels. Black-headed Grosbeaks typically begin to lay eggs 2–3 days after nest-building ends. So far as is known, members of the family lay eggs sequentially, one per day, until the clutch is complete. Laying normally takes place early in the morning, within an hour after sunrise in the case of Black-headed Grosbeaks and Indigo Buntings, but as late as three hours after sunrise in the Rose-breasted Grosbeak.

In general, eggs of cardinalids range in colour from whitish to blue or greenish-blue, usually with some degree of brown, black or purplish mottling, spotting or streaking, particularly around the blunt end. Blue-black Grosbeak eggs, for example, are either white or tinged with blue, blotched and marked with chestnut, reddish-brown or pale lilac. Indigo Buntings, Dickcissels and some other species normally lay unmarked eggs. Some Indigo Bunting clutches contain both unmarked and spotted eggs, but there is no evidence to suggest that these are laid by different females.

Members of the family breeding in temperate climates normally lay three or four eggs in a clutch. Dickcissels may lay as many as six, although a proportion of the eggs may be sterile, possibly as an adaptive response to the ability of the female to provision a large brood. Dickcissel second-brood clutches on the Kentucky–Tennessee border contained, on average, about one egg fewer than those of first broods. Clutch size of tropical species is generally lower, between two and three eggs. One Black-faced Grosbeak clutch contained three dull white eggs, mottled and spotted with brown. The Blue-black Grosbeak lays two eggs, a typical clutch for a tropical passerine.

The clutch size of Northern Cardinals in Bermuda is significantly lower, by 18·2%, than that of the species in coastal North

So far as is known, all saltators have open cup-nests, although the nests of a few species have not been described. The ***Greyish Saltator*** *builds a bulky cup with a foundation of twigs, a middle layer of small leaves, and a thick lining of fine fibres and rootlets. Saltator nests are normally situated low in a bush or tree. In one of the few saltator species to have been studied in detail, the Buff-throated Saltator* (Saltator maximus)*, the female apparently builds her nest unassisted, although the male remains in attendance and brings her food. The female Buff-throated Saltator also incubates the eggs alone.*

[*Saltator coerulescens coerulescens*, Mato Grosso, Brazil. Photo: Anita Studer]

American habitats at similar latitudes. As cardinals have been in Bermuda for only a few centuries, Crowell and S. I. Rothstein believe that this probably represents not an evolutionary change, but a fine-tuned response to proximate factors in the environment, including a more stable climate.

Among most cardinalids for which the relevant information is available, incubation is carried out by the female alone, as typified by, for example, the Black-faced and Blue-black Grosbeaks, although the male usually stays in the vicinity. Incubation normally does not begin until the last egg or the penultimate one is laid, although Rose-breasted Grosbeaks may start to sit as early as the second day of laying, and female Northern Cardinals sometimes sleep on the nest after depositing the second of a three-egg clutch.

Males of the Indigo Bunting and the Dickcissel ignore the female during incubation. On the other hand, male Northern Cardinals, Pyrrhuloxias and Blue Grosbeaks may bring food to the female as she sits on the nest. When the female Black-faced Grosbeak returns to the nest, the male accompanies her in a looping flight as both birds sing. Skutch once recorded a female accompanied in this fashion by two other individuals, one presumably a helper (see above).

Males of the Rose-breasted, Black-headed and Golden-bellied Grosbeaks undertake some of the task of incubating the eggs, but the role of the male of other *Pheucticus* species is apparently not known. In the case of the Rose-breasted Grosbeak, the male may be responsible for one-third of the incubation work during the day, and male Black-headed Grosbeaks have been recorded as contributing up to 50% of the daytime incubation. Male grosbeaks may develop bare areas of skin similar to the brood patch of the female, but less heavily vascularized. Females apparently do all of the incubation at night.

Female Indigo Buntings spend up to 79% of the daytime hours incubating. The female Blue-black Grosbeak stays on the nest for approximately 70–75% of the time, but may incubate for as much as 95% of the day in rainy weather. One Blue-black Grosbeak observed by Skutch on a cool rainy day spent six hours in continuous incubation, the longest period that he recorded for any passerine bird. At two of three nests that Skutch observed, the male occasionally brought food to the female while she sat on the eggs.

The eggs generally hatch after 11–14 days, 12 days being the average for most cardinalid species. Young Northern Cardinals may take from 12 to 24 hours to break out of the egg, whereas Dickcissels can free themselves from their shell within a few minutes. The entire brood usually hatches over the course of one or two days. The young usually emerge unaided, but occasionally a female Northern Cardinal will lend assistance. Hatchling cardinalids are sparsely covered with down, generally either grey

The female ***Pyrrhuloxia*** *does most, if not all, of the nest-building. The result is similar to, though smaller and more compact than, the nest of the Northern Cardinal* (Cardinalis cardinalis)*. An oval cup made from thorny twigs, strips of bark and coarse grasses, it is lined with rootlets, spider webs, feathers and other fine fibres. The nest is placed 2·4–4 m up in a mesquite* (Prosopis)*, catclaw* (Acacia greggii) *or similar shrub, and sometimes in a clump of mistletoe. Northern Cardinals and Pyrrhuloxias do not attach the nest to the surrounding branches, but simply wedge it into place. The female Pyrrhuloxia begins to lay her eggs within six days of completing the nest.*

[*Cardinalis sinuatus sinuatus*, Texas, USA. Photo: John Cancalosi/ DRK]

Dead vines, coarse twigs and leaves are among the materials which go into the bulky nest of the ***Buff-throated Saltator****. The nest is usually 0·3–2 m above ground, occasionally higher, in a bush or tree, but sometimes in a dense stand of bracken or compact tuft of tall grass. Having built the nest alone, the female may begin to lay her eggs on the day after completion, or up to four days later; the eggs are laid on consecutive days. The nests of this species are usually well separated, but on one occasion two were found only 2·4 m apart. These two females had different mates but one female was dominant, frequently chasing the other from the nest.*

[*Saltator maximus maximus*, Estação Veracruz, Ribeirão Ronca Água, Santa Cruz de Cabrália, Bahia, Brazil. Photo: Dante Buzzetti]

or white in colour. The colour of the mouth-lining ranges from orange to deep red, with yellow flanges or edging at the gape. Lazuli Bunting hatchlings retain the egg tooth for up to three days. The eyes of hatchlings are initially closed; they may open by three days in Painted Buntings, by five or six days in Varied Buntings, and by as late as eight days in Black-headed Grosbeaks. Black-headed Grosbeaks grow in weight from 3 g to about 35 g during their time in the nest.

With many species, including the Black-faced Grosbeak, only the female broods the nestlings, but males of the Rose-breasted and Black-headed Grosbeaks brood occasionally, the Rose-breasted Grosbeak doing up to 25% of the daytime brooding. Brooding sessions are often short; in 1915, I. N. Gabrielson noted that brooding stints of a nesting Rose-breasted Grosbeak lasted for an average of seven minutes each, stretching to 17 minutes in the last two days, when the female brooded not by sitting, but by standing on the nest with wings slightly spread. Brooding of chicks is most continuous in the first few days after hatching, before the young are able to control their own body temperatures. Northern Cardinals are able to thermoregulate by five days of age, and Dickcissels by six days. A female Dickcissel watched by A. O. Gross brooded her young closely for the first three days, when ambient temperatures rose to above 32°C, but she was less attentive on days three and four and did not brood after day six. A six-day-old nestling left alone in the nest for one hour maintained an internal temperature of 41°C, even though the ambient temperature was only 26·6°C.

Nestlings are usually fed mostly with animal matter, including grasshoppers and caterpillars. Pyrrhuloxias may feed their young with cactus fruit, as well as insects. Rose-breasted Grosbeaks include a small percentage of seeds, which they may shell at the nest before passing the kernels to their young. Female Dickcissels, which tend their young alone, may start feeding as little as 30 minutes after a chick hatches. One was seen to bring grasshoppers to a five-day-old brood of four chicks at the rate of 20 per hour.

Both sexes of *Cardinalis* and of North American species of *Pheucticus* feed young in the nest. Male Northern Cardinals studied in Ohio were, unusually for such a highly dichromatic species, assiduous in tending their young, adjusting their efforts to the size of the brood to an even greater degree than females, and increasing their feeding rates as nestlings aged. T. S. Filliater and Breitwisch explored a number of potential explanations for this, including the possibility that females may threaten their mates with divorce if they do not measure up. A later study of the same population found that, on the basis of reactions to models of predators, males contributed equally with females to nest defence during the middle of the nesting period, although defence seemed to be only a minor factor in nesting success. Males of the Vermilion Cardinal, another highly dimorphic species, are similarly attentive to their young.

Among *Passerina* species, the female normally takes responsibility for most or all of the care of the nestlings, including feeding. Male Lazuli Buntings are highly variable in their contribution to nestling welfare, but in one Montana study males were responsible for 24·6% of feeding visits to the nest. Male Painted Buntings apparently do not feed their nestlings, and Varied Bunting males do so only after the fourth or fifth day. Indigo Bunting males usually do not feed the chicks directly, but may do so to a limited extent nearer the time when the young leave the nest, and may pass food to the female; she then feeds it to the chicks. Monogamous male Indigo Buntings are more likely to feed their young than are polygynous ones.

Although both sexes of the Blue Grosbeaks observed by Alsop in Tennessee fed their young, most feeding and all of the prey capture, involving mostly large mantids (see Food and Feeding), was done by the female. Keyser and Hill found that female Blue Grosbeaks fed their nestlings more than six times more frequently than did males. Male Blue Grosbeaks may feed young from a first brood while the female is building a nest for the second, as male Rose-breasted Grosbeaks will do on the rare occasions when a female renests. Similarly, male Painted Buntings will take over the care of an earlier brood while the female tends to a later one. Blue-black Grosbeak nestlings are fed by both parents, and Black-faced Grosbeak nestlings are provisioned both by parents and by helpers (see above). H. Brackbill recorded a juvenile Northern Cardinal that fed nestlings raised by its presumed parents; the juvenile also begged from the adults, and the male did feed it, though the female attempted to drive it away.

Dickcissel males normally take no part in the feeding of the young. Gross recorded a male that failed to feed his young even

Incubation does not usually begin until the last egg or the penultimate egg is laid, although the ***Rose-breasted Grosbeak*** *may start to sit as early as the second day of laying. The clutch size of this species is 3–5 eggs, usually four. Both sexes sit, although the female spends twice as much time on the nest during the day and sits exclusively at night. Between them, the partners reportedly keep the eggs almost continuously covered. The incubation period for this species is 12–13 days.*

[*Pheucticus ludovicianus*, George W. Mead Wildlife Area, Wisconsin, USA. Photo: Gerard Fuehrer/ DRK]

after the death of the female parent; the brood starved to death. The male's contribution, however, is apparently variable. In a population of Dickcissels studied in east-central Illinois, J. D. Maddox and E. K. Bollinger recorded males feeding young at six out of eight nests during 1997, males accounting for 37% of total visits to all nests. This unusual behaviour may have been prompted by a scarcity of food, although this was not assessed. In the following year, when food was presumably more abundant, no males were recorded as visiting nests.

Except in a few species, such as the Dickcissel, both sexes generally carry away the nestlings' faecal sacs, although in the first days after hatching the adults swallow the droppings, rather than remove them. Lazuli Bunting females have been seen to insert the bill deep into the bottom of the nest and to shake the nest vigorously for 10–15 seconds. The function of this behaviour is unknown, but it may have the effect of shaking ectoparasites lower into the nest.

Although male Indigo Buntings often leave most of the nesting duties to the female, they may help to defend the nest. Black-headed Grosbeaks react to potential threats by flying from branch to branch, uttering loud distress calls. As the young in the nest grow older, and thereby represent a greater cumulative parental investment, the calls begin sooner, and increase in number, at the first approach of a threat. Similarly, Westneat found that Indigo Buntings give many more alarm calls per minute when disturbed during the nestling phase than when a potential threat appears during incubation.

Young cardinalids generally leave the nest at between 9 and 12 days of age. Some exceptions to this are presented by Northern Cardinals, which sometimes depart at only 7 days, especially if disturbed, and Black-faced Grosbeaks, which have been recorded as remaining in the nest for 15 days. Blue-black Grosbeak nestlings are fully feathered by 10 days, and leave the nest after 11 or 12 days, as do most Black-faced Grosbeaks.

In the case of the Painted Bunting, skull pneumatization takes an estimated 46 days to complete. In the Black-faced Grosbeak, skull pneumatization is completed posteriorly, rather than anteriorly, a pattern seen in a number of tropical species.

After having left the nest, the young may move very little for the first few days, up to eleven days in the case of the Northern Cardinal, but they gradually acquire more mobility and independence. Juvenile Pyrrhuloxias start to form flocks as early as July, and young Blue Grosbeaks form flocks that are later joined by parent birds and the offspring from later broods. Male Black-headed Grosbeaks sometimes leave the breeding area before either females or young, and the last young of the year often do not depart until several weeks after the last adults.

Parents continue to feed their young for several weeks after fledging, Lazuli Buntings and some Dickcissels doing so for two weeks and some other species for longer, and the young may continue to associate with their parents for some time after they are able to feed themselves. Rose-breasted Grosbeaks in southern Ontario are dependent on their parents for three weeks after leaving the nest, before they disperse from the natal area. One juvenile Northern Cardinal in Maryland, in the eastern USA, was independent by 50 days, but it associated with its parents for a further 20 days. Dickcissel fledglings studied by K. M. S. Wells and her colleagues in south-western Missouri were independent after two weeks, but they moved little until four weeks after fledging. Some Dickcissel young may be dependent on their parents for four weeks or more after leaving the nest. Indeed, one parent observed by Walk and his colleagues in south-eastern Illinois continued post-fledging care for 43 days. This long period of post-fledging care may be a factor explaining why most Dickcissels are single-brooded. Male Painted Buntings observed by Parmelee attended their young fledglings, but normally did not feed them unless the female was engaged in constructing another nest. One male took over care of his brood six days after they had left the nest, while the female was renesting. Parmelee has suggested that the ability of polygynous male Painted Buntings to care for fledged broods may be the critical factor determining whether a female renests.

Some odd associations between parent Northern Cardinals and other species have been recorded. A pair of cardinals in Maryland shared a nest with a pair of Song Sparrows (*Melospiza melodia*); both species fed the young and cleaned the nest. A Canyon Towhee (*Pyrgisoma fusca*) has been recorded as actively feeding fledged cardinals for a period of three weeks; the true parents were in attendance and accepted the assistance. In contrast, a male Northern Cardinal was observed when feeding a

brood of fledgling American Robins (*Turdus migratorius*) over a period of several days while provisioning his own young, and another male was recorded as tending a nest containing three young Yellow-breasted Chats (*Icteria virens*). In another interesting case, a female cardinal in Iowa shared a nest with an American Robin, the nest containing three robin eggs and two cardinal eggs. The two females, attended by their respective mates, incubated the eggs separately or together, the two sitting side by side on the nest, although only the robin chicks fledged successfully. As the female cardinal became increasingly aggressive to the female robin over time, it may be that this behaviour was the outcome of competition for a suitable nest-site. Finally, there are recent records of fledgling Carolina Wrens (*Thryothorus ludovicianus*) taking refuge in a newly lined cardinal nest during inclement weather, and of a failed cardinal nest being used by a Grey Catbird in the same season, but there was apparently no direct interaction between the two species in either case.

Conspecific brood parasitism is suspected in less than 1% of Indigo Bunting nests in Michigan, but is otherwise rare or absent in this family. There is one recent record of the appearance of three eggs in a Dickcissel nest, already containing four, during a two-day period. As Dickcissels lay only one egg per day, one of the eggs must have been laid by another female.

Every cardinalid species breeding north of Mexico is a known host of the Brown-headed Cowbird. In addition, Bronzed Cowbirds (*Molothrus aeneus*) have been recorded as parasitizing Northern Cardinals, Pyrrhuloxias and Painted Buntings. Shiny Cowbirds (*Molothrus bonariensis*) are known to parasitize Golden-bellied Grosbeaks and some saltators (see below). Cowbirds may be particularly attracted to Northern Cardinals because the latter's bright colours and conspicuous behaviour make their nests easier to find. A high density of cardinals in the area was the most important factor influencing the rate of cowbird parasitism of the Black-capped Vireos (*Vireo atricapilla*) in Texas. Despite this, young cowbirds often do not survive well in cardinal nests. Cardinals studied by D. M. Scott and Lemon at London, in Ontario, produced only about 25% of the number of young cowbirds successfully raised by other host species, particularly in mixed broods, in which the young cowbirds were often underweight and grew poorly. Unlike some other hosts, Northern Cardinals have an incubation period only slightly longer than that of cowbirds, so that parasite eggs laid after incubation has begun are less likely to hatch.

The frequency with which cowbirds parasitize members of this family varies among both species and populations. The Indigo Bunting is one of the 17 most frequent cowbird hosts throughout its range, and one of the seven most heavily parasitized species in the Atlantic coastal plain and Piedmont regions of South Carolina and Georgia. Similarly, as many as 71–100% of Lazuli Bunting nests were parasitized by cowbirds in the Sacramento Valley, in California, as were at least 50% of Blue Grosbeak nests in Grand Canyon National Park, in Arizona. Rose-breasted and Black-headed Grosbeaks are rarely parasitized, usually fewer than 10% of nests being affected. Aggressive behaviour and nest-guarding by these host species may keep parasitism rates low. Nevertheless, 23% of nests were recorded as being parasitized in the zone of range overlap between the two grosbeak species, and one Black-headed Grosbeak population in British Columbia, in south-west Canada, had a parasitism rate of 35%.

Dickcissels and Bell's Vireos (*Vireo bellii*) were the two species most heavily parasitized by Brown-headed Cowbirds at the Konza Prairie Biological Station, in north-east Kansas, between 2002 and 2007. Their rates of parasitism, 69·6% for the Dickcissel and 70·5% for the vireo, were considerably higher than those for the next most heavily parasitized species, the Red-winged Blackbird, for which the rate was 21·9%. Some other species on the station, including the Blue Grosbeak, had 100% of their nests parasitized, but the number of nests involved, only four in the case of the grosbeak, was much smaller. On the Konza Prairie the Dickcissel appeared to be the cowbird's preferred host. A Dickcissel can fledge up to five cowbirds from a single nest, and, unlike the vireo, it rarely abandons a nest with cowbird eggs in it. In terms of the number of young cowbirds that these nests produced, Dickcissels led the way, with 1295 fledged offspring from 619 parasitized nests over the course of the study. These parasitism rates were in fact lower than the figure of 84·7% calculated by Zimmerman for the same site from data collected between 1965 and 1979.

Throughout the first two days after hatching, ***Northern Cardinal*** *chicks are brooded intensively by the female. During this period, the male may feed her, as well as the chicks. The male also feeds the female on or away from the nest during the 11–13 days of incubation, which is done by the female alone. In one study, females fed more often during incubation tended to provision their nestlings less. Unusually for such a highly dichromatic species, male Northern Cardinals are assiduous in tending their young, adjusting their efforts to the size of the brood to a greater degree than females and increasing their feeding rates as nestlings age.*

[*Cardinalis cardinalis cardinalis*, SW Ohio, USA. Photo: Dave Maslowski/ Maslowski Productions]

A study in Tennessee found that the female Blue Grosbeak feeds her nestlings more than six times more frequently than does the male. Male ***Blue Grosbeaks*** *may feed a first brood while the female is building a nest for the second, and become more involved after the young fledge. In some cardinalids, such as the Northern Cardinal, rates of extra-pair copulation are relatively low. But in Alabama, 53% of Blue Grosbeak nestlings were found to have been sired by another male, and 70% of nests had at least one extra-pair chick. Males with dull plumage coloration were more likely to be cuckolded than those with more brightly coloured plumage, but duller males did not guard their mates more. Instead, males with more brightly coloured neighbours guarded their mates more closely than did males with fewer colourful neighbours. Brighter males tend to be larger and to have larger and higher-quality territories. They are not better at feeding their offspring, but, since this is largely the female's responsibility, the quality of territory may be more important. In fact, female Blue Grosbeaks may choose mates indirectly by assessing territory quality, rather than by assessing the male's quality by his plumage.*

[*Passerina caerulea caerulea*, N Kentucky, USA. Photo: Dave Maslowski/ Maslowski Productions]

Cowbird parasitism rates can range from zero to 100% for one and the same species. In the case of Lazuli Buntings, nests situated close to cowbird roosts may suffer very high parasitism, while more distant ones experience none. Yearling birds may experience higher rates of parasitism than older ones, perhaps because older birds are more likely to occupy territories with greater opportunities for nest concealment. Among Dickcissels, parasitism rates range from non-existent, as in prairie barrens on the Kentucky–Tennessee border, to 100%, with the heaviest rates in the Great Plains. The reasons for this variation are not altogether clear. Rates have been reported to be highest in areas where nest density is low, and vice versa, but this was not the case in the Flint Hills of Kansas and Oklahoma, where cowbird parasitism, in a study by W. E. Jensen and J. F. Cully, varied from zero to 92% along a latitudinal gradient from south to north on ungrazed prairie, with no apparent correlation between parasitism and habitat features. In an earlier study in the same region, however, the Dickcissels experienced their highest levels of brood parasitism in unburnt hay fields, where nest density was about half that on restored prairie grasslands (see Habitat).

Habitat may not always be a factor in determining the risk of cowbird parasitism (but see Habitat). For example, Indigo Buntings in West Virginia were more likely to be parasitized by cowbirds if the vicinity of the nest had lower cover and a greater number of tall snags, but for Indigo Buntings in Michigan the habitat, including the choice of nest-site, seemed to make no difference.

Parasitism rates can vary through the season, making estimates based on short-term studies unreliable as general guides. Parasitism of Indigo Bunting nests decreases through the late spring and summer, because cowbirds stop laying before the buntings embark on late-season clutches. At the Edwin S. George Reserve, in Michigan, the Paynes found that, while parasitism rates were 23% in May and 26% in June, they declined to 9% in July and reached zero in August. At Niles, also in Michigan, more than half of Indigo Bunting clutches were begun after the peak of the cowbird season had passed.

Lazuli and Indigo Buntings will desert a nest if a cowbird lays in it first, whereas a Northern Cardinal in the same situation may not desert. A Blue Grosbeak will reportedly build a new nest on top of its old one if a cowbird has laid eggs in it. In many cases, however, birds will simply accept cowbird eggs, and the reproductive cost of brood parasitism may be slight.

The presence of cowbird chicks seems to have no effect on the ability of Northern Cardinals and Rose-breasted Grosbeaks to raise their own young. K. P. Eckerle and Breitwisch, who studied the effects of parasitism on Northern Cardinals in Ohio, observed adults taking action against cowbirds only at three parasitized nests, 5% of the total. Two abandoned the nest without laying, and a third buried the cowbird egg under new nesting material.

Other species do not fare so well if cowbirds lay in their nests. Cowbirds may remove eggs of the hosts before laying in the nests of Dickcissels, Indigo Buntings and other species. Cowbirds may also break eggs by pecking at them. It has been suggested that an unusual statistical difference in eggshell mass between western and eastern populations of Painted Buntings, western females laying eggs with heavier and presumably less fragile shells, may be a response to the historical presence of egg-pecking cowbirds in the range of the western birds, and their absence, until comparatively recently, among the eastern population (see Status and Conservation). Pyrrhuloxias in Texas fledge very few young if they have been parasitized by cowbirds; in one parasitized brood, two Pyrrhuloxia chicks were found trampled to death in the bottom of the nest. Parasitized Dickcissel nests also reportedly fledge fewer young than unparasitized ones. Cowbird-removal experiments in the Flint Hills nonetheless made no difference to nest productivity, despite a parasitism rate of more than 80%, with multiple cowbird eggs per nest. This may have been because the cost of parasitism was swamped by the much greater effects of nest predation, which was responsible for the overwhelming majority of nest failures.

M. A. Whitehead, S. H. Schweitzer and W. Post monitored nests of Northern Cardinals, Blue Grosbeaks and Indigo and Painted Buntings on James Island, in South Carolina, in order to determine the effect of cowbird parasitism on nesting success. Parasitism reduced the mean clutch size, but not the hatching rate, for all four species, and reduced the fledging rate for Blue Grosbeaks. It had little effect overall on the seasonal fecundity of the hosts, which were still able to raise young successfully.

*The female **Dickcissel** may start feeding a chick as little as 30 minutes after it has hatched. Usually, the female feeds the chicks alone. One was seen to bring grasshoppers (Orthoptera) to a five-day-old brood of four chicks at the rate of 20 per hour. Dickcissel males are polygynous, and the most successful may have up to six mates. Of 150 males in a Kansas study, 14% (mostly yearlings) had no mate, 41% had two and 9% had three or more. Female productivity is not adversely affected by male polygyny. In fact, one study found the reverse to be true: a greater percentage of eggs hatched, and fledging rates were higher, for females mated to polygynous males. This may be related to the quality of the territory.*

[*Spiza americana*, Illinois, USA. Photo: Richard & Susan Day/VIREO]

*The male and female **Buff-throated Saltator** mash food items thoroughly in the bill before offering them to the nestlings. Both parents feed and attend the young. A male was seen feeding a nestling only two hours after it had hatched. At two nests of this species, the nestlings were fed, respectively, 86 and 59 times over a total of 15 hours. The young, usually two, remain in the nest for 13–15 days, but continue to be attended by both parents until they are 50–55 days old. Despite this extended fledgling dependency, Buff-throated Saltators have at least two broods in some areas.*

[*Saltator maximus magnoides*, El Copal Private Reserve, near Tapantí National Park, Costa Rica. Photo: Marco Saborío]

Indigo Bunting nests parasitized by cowbirds may be less likely to fledge young: in a survey of undisturbed nests in which at least one egg was laid, 56·4% of 1310 unparasitized nests were successful in fledging at least some nestlings, but only 19·5% of 411 parasitized nests did so.

Egg removal and loss probably represent the most serious cost of parasitism to Indigo Buntings, but the presence of cowbird young imposes costs of its own. Indigo Bunting nests with only one cowbird egg were more likely to produce young than were those with two or more, 22·1% of 339 nests with one egg being successful, compared with only 6·9% of 72 nests containing two or more cowbird eggs. Young cowbirds hatch a day or two earlier and grow more quickly than young buntings. They outcompete and overcrowd their smaller nestmates, and may even push them out of the nest. In captive mixed broods studied by R. B. Payne, the nestling cowbirds trampled the nestling buntings, climbed on them and pecked them about the head. A nestling cowbird has been videotaped as it ejected an Indigo Bunting chick from the nest, but it is not known how common such behaviour is. Young cowbirds even affect the survival of Indigo Bunting chicks after they have left the nest, presumably by competing for the attention of their foster parents.

The presence of cowbirds can have an adverse effect on general health and fitness of the host's young. D. C. Dearborn and his colleagues found that Indigo Bunting chicks in parasitized nests received less food, begged more, gained mass at a slower rate, and were generally in poorer condition than nestlings from cowbird-free broods. Parasitized nests are more likely to succumb to predators, possibly because adults are forced to make more provisioning visits to the nest and can therefore spend less time in guarding their brood. Only 1·7% of young Indigo Buntings fledged from parasitized nests in Michigan returned in the following year, compared with 9·3% of young raised without cowbirds.

Predation is the single most important reason for nest failure, as it is for most passerine birds. While parasitism on James Island was directly responsible for only 2·9% of nest failures for four cardinalids and two other passerines, predation by other birds and reptiles caused 84·1% of nest losses, with additional failures due to predation by mammals and fire ants (*Solenopsis*). Nest predation by birds, snakes or mammals, including squirrels (Sciuridae) and northern raccoons (*Procyon lotor*), is the primary cause of nest failure among Rose-breasted and Black-headed Grosbeaks. Rose-breasted Grosbeaks reacted to a nest-raiding American red squirrel (*Tamiasciurus hudsonicus*) with a series of screams and threat displays that involved either tilting the head upwards and ruffling the wings or spreading and waving the wings, presumably to expose the colourful underwing-coverts. C. P. Ortega and J. C. Ortega identified the main nest predators in Black-headed Grosbeak habitat in riparian and oak pastures in Colorado as Black-billed Magpies (*Pica hudsonia*), Western Scrub-jays, Steller's Jays, rock squirrels (*Spermophilus variegatus*), chipmunks (*Tamias*), deer mice (*Peromyscus maniculatus*), long-tailed weasels (*Mustela frenata*), striped skunks (*Mephitis mephitis*), northern raccoons, and garter snakes (*Thamnophis*).

Rose-breasted Grosbeaks in southern Ontario woodlots suffered a 63% predation rate, 95 of 151 nests being lost. Black-headed Grosbeak nests studied by the Ortegas in Colorado had a much better success rate, only 37% of 41 nests entirely failing owing to predation. Indeed, the grosbeaks had the highest success rate of passerines in the area, even though their nests, which were sometimes decorated with the purple flowers of lupines (*Lupinus*), appeared conspicuous to human observers. Their high success rate may have been due to aggressiveness in nest defence by both parents.

The eastern racer (*Coluber constrictor*), a non-venomous snake, has been seen to swallow a clutch of Dickcissel eggs in the Flint Hills, in Kansas, and to attempt to seize a nestling Indigo Bunting in Missouri. Blue Jays (*Cyanocitta cristata*) and Common Grackles (*Quiscalus quiscula*) kill young Rose-breasted Grosbeaks. Steller's Jays and Western Scrub-jays are the chief predators of Black-headed Grosbeak nests, but gopher snakes (*Pituophis catenifer*) also take this species' eggs and squirrels take its young. Plush-crested Jays (*Cyanocorax chrysops*) frequently raid the nests of Black-backed Grosbeaks. A Barred Forest-falcon (*Micrastur ruficollis*) has been seen to eat a fledgling Blue-black Grosbeak in Panama, and a Montezuma Oropendola (*Psarocolius montezuma*) was seen to kill a young Black-faced Grosbeak in Costa Rica.

*The male **Rose-breasted Grosbeak** shares in brooding as well as feeding the young. Along with insects, the parents bring a small percentage of seeds, which they may shell at the nest before passing the kernels to the chicks. In the conspecific Black-throated Grosbeak* (Pheucticus melanocephalus), *males and females contribute equally to the feeding of the young throughout the nestling period. The number of feeding trips to the nest was found to remain rather constant throughout that period. As the nestlings grew, however, the adults appeared to bring larger food items, and frequently brought more than one item per trip. In Rose-breasted Grosbeaks, the nestling period is about ten days, but the young are incapable of flight for 2–5 days after leaving the nest, and stay close by.*

[*Pheucticus ludovicianus*, Michigan, USA. Photo: John Gerlach/DRK]

Only an estimated 15% of 121 Northern Cardinal nests monitored in south-western Ohio were ultimately successful. The others were all known or suspected to have been preyed upon. Choice of nest-site appeared to have no effect on the final outcome. Instead, the birds' chief response to a large and varied guild of nest predators, including snakes, squirrels and crows, each with its own micro-habitat preference and search strategy, appears to be the ability to renest rapidly after failure. Cardinals may start a new clutch as little as four days after the loss of an earlier one.

Of 45 Painted Bunting nests found by Parmelee in Oklahoma, only 15 produced fledglings, yielding a total of 37 young. In Kansas, Zimmerman found that nest predation was higher among Dickcissels nesting in old fields than for those in prairie, presumably because predators, especially snakes, are more common in old-field habitats. Predation reached a peak in July, the middle of the nesting season, when nest density was also at its height. Dickcissels that fail in a first nesting attempt may emigrate elsewhere. For example, 62% of Dickcissels studied in south-eastern Illinois relocated more than 10 km away before renesting, in one case moving as much as 32 km. Renesting efforts began 4–15 days after failure, with an average interval of 8·5 days. Although successful Dickcissels generally did not renest, only 2% of those in the study abandoned nesting attempts after a first failure.

The period immediately after fledging, before the young have acquired flight skills, is the most critical for the survival of young. Rose-breasted Grosbeaks are incapable of flight for the first 2–5 days after leaving the nest, and move only short distances from the nest-site. L. C. Moore and his colleagues, in a study of a population of Rose-breasted Grosbeaks in fragmented forests in southern Ontario, found that 86% of total fledgling mortality occurred during the first week after fledging, mostly during the first five days. During this time the young usually remained perfectly still, even when approached closely. They seemed to rely for protection mostly on camouflage and parental defence. Older fledglings, when approached, reacted by moving higher in the vegetation, and tended to stay higher in the canopy, where predators may be less frequent. As the post-fledging period progresses and the young fly better and beg less, their risk of succumbing to a predator decreases and their likelihood of survival improves. Overall fledgling survival in this population was 0·62 for the three-week post-fledging period, a figure comparable to that for other small passerines.

Mortality rates for fledgling Dickcissels in the Missouri Valley were also highest during the first week after departure from the nest. Only 33% survived the first four weeks after fledging. Predation was a major cause of mortality, snakes, including garter snakes and fox snakes (*Elaphe vulpina*), being key predators of both nestlings and fledged young. Most mortality occurred when young birds were within 10 m of the nest-site, and it could be that the density of vegetation cover in the area near the nest is key to fledgling survival. In another studied population in south-eastern Missouri, only 56% of fledglings survived their first two weeks.

Fragmented landscapes frequently expose birds to higher rates of nest predation, as well as brood parasitism (see General Habits). L. A. Smith and her colleagues found that Rose-breasted Grosbeaks in heavily cut woodlots in southern Ontario tended to select lower, better-concealed nest-sites than did birds in lightly logged stands with a less open canopy. Such sites may have exposed the grosbeaks to higher levels of nest predation, and did expose them to higher rates of parasitism.

D. Morris measured the cost to female Indigo Buntings in fragmented forests in Missouri of having to replace a brood lost to a predator. She found that, although renesting could replace lost young, it did so at the expense of females' physical and physiological state. In the fragmented landscape, only 34% of females were able successfully to raise young on their first attempt, compared with 61% in contiguous forest. Birds that lost nests to predators often began another attempt 3–5 days later, perhaps before the females had had time to recover physiologically. Renesting buntings suffered poor body condition and high acute corticosterone levels, and produced young that were themselves in poor condition.

The genera *Parkerthraustes* and *Saltator* are thought not to belong with the true cardinalids (see Systematics), and they are, therefore, treated separately in this section. It appears, however, that nothing is known about the nesting habits of the genus *Parkerthraustes*, the Yellow-shouldered Grosbeak, and, aside

Like the male Northern Cardinal (Cardinalis cardinalis), *the male* ***Vermilion Cardinal*** *is a conscientious parent, contributing as much to the feeding of his offspring as does his mate. In the third member of the genus, the Pyrrhuloxia* (C. sinuatus), *the young are apparently fed more by the female. The diet of nestling Vermilion Cardinals is not known, but is probably largely insects, as with its congeners. Pyrrhuloxias may additionally feed their young with cactus fruit. Northern Cardinals are usually double-brooded, but Vermilion Cardinals and Pyrrhuloxias apparently do not raise a second brood, or, in the case of the Pyrrhuloxia, are rarely successful if they try.*

[*Cardinalis phoeniceus*, Península de Macanao, Isla Margarita, Nueva Esparta, Venezuela. Photo: Roland Seitre]

from Skutch's observations on the Buff-throated and Streaked Saltators in Costa Rica, the breeding biology of *Saltator* has not been studied in detail.

The breeding season of saltators varies with species and geographical location. In central and northern South America, it may extend from March or April to August, although records outside this period exist. In Argentina and Uruguay, the season is primarily from October to January. The Greyish Saltator breeds between March and October in Trinidad, but between October and January in Argentina.

So far as is known, all saltators build an open cup-nest, although the nests of three of the species, the Black-throated Grosbeak and the Black-cowled and Masked Saltators, remain to be described. Nests are constructed variously from twigs, leaves, roots and dry grasses, and lined with finer material. The nests of the Buff-throated and Black-headed Saltators have been described as bulky, and Skutch reported that the Buff-throated Saltator's nest was considerably bulkier than that of the Streaked Saltator.

Saltator nests are normally situated low in a bush or tree, in general not above 4 m, but occasionally they are higher, particularly in the case of the Lesser Antillean and Streaked Saltators. Of 22 Streaked Saltator nests studied by Skutch, 16 were placed between 1·2 m and 2·4 m above the ground, and one was as high as 6 m up in a mango tree (*Mangifera*). Buff-throated Saltators may nest in dense stands of bracken or compact tufts of tall grass in a pasture, and Orinoco Saltators will nest in cane. A Black-winged Saltator nest in north-western Ecuador was supported by pasture grass.

Female Buff-throated Saltators apparently build their nests alone. The male does, however, stay in attendance, bringing food to the female and singing responsively with her during building. Nest-building can take 3–6 days, whereas nests constructed later in the season are usually built in three or four days.

The usual clutch size of saltators is two eggs or, less commonly, three. Egg-laying by Buff-throated Saltators can begin on the day after the completion of the nest or up to four days later. Once laying commences, eggs are laid on consecutive days. The first egg is normally laid in the hour following sunrise, the second one following some 26 hours later. Saltator eggs are blue, bluish-white or bluish-green, generally marked with blackish to brownish spots or streaks. In the case of both Buff-throated and Streaked Saltators, incubation is by the female alone, and is not continuous. Skutch recorded one female Buff-throated Saltator that, during a 12-hour observation period, devoted 66% of her time to sitting on the eggs, which she did in 18 bouts ranging from 6 to 52 minutes in length. Other females spent about the same amount of time in incubating, from 60% to 66%. Streaked Saltators incubate for similar periods, with longer sessions on rainy afternoons. The male Buff-throated Saltator may visit his mate during incubation, while the male Streaked Saltator is more likely to approach the nest when the female is absent. Both species, however, will feed the female at times as she incubates.

The eggs hatch after 13 or 14 days. Newly hatched Buff-throated Saltators have pink skin with a few tufts of long, olive-green down and a red mouth-lining. The young are fully fledged by about 12 days of age, and leave the nest at 13–15 days. For the first few weeks out of the nest, they remain in dense cover. A Streaked Saltator chick was fully fledged by 11 days and left the nest at 13 days.

Both parents, at least of the Buff-throated and Streaked Saltators, feed and attend the young, although apparently only the female broods. Streaked Saltators feed their chicks on a mixed diet of fruit and insects. Skutch observed a male Buff-throated Saltator that fed a nestling only two hours after the latter had hatched. Visiting parent Buff-throated Saltators mashed food items thoroughly in the bill before offering them to their nestlings. At two nests of this species, situated 2·4 m apart in coffee bushes, which Skutch watched over a total of 15 hours, the nestlings were fed 86 and 59 times and brooded for 193 and 226 minutes, respectively. Young Lesser Antillean Saltators are likewise attended by both parents. Apparent helpers at the nest have been recorded for the Black-throated Saltator (see General Habits).

Buff-throated Saltators in Costa Rica raise at least two broods in a season, and replace clutches lost to predation. Skutch recorded that nest predation was high for both Buff-throated and Streaked Saltators. In addition, Black-throated Grosbeaks and Green-winged and Greyish Saltators have been recorded as hosts of the Shiny Cowbird.

*This male **Blue Grosbeak** is delivering a large mantid (Mantidae) to his offspring, but he probably did not catch it. All of the prey capture observed among five pairs of parent birds in Tennessee was done by the female. Mantids more than 75 mm long accounted for 96% of the items delivered to the chicks at these five nests. The females, followed by their mates, plucked the mantids from weedy vegetation while in short or hovering flight, or while hopping on the ground. Before feeding them to the young, the adults removed the head, wings and most or all of the legs.*

Movements

Cardinalidae includes not only resident species, but also long-distance, short-distance and altitudinal migrants. Mexican and Neotropical species are largely sedentary, although Crimson-collared Grosbeaks and Blue Buntings have been recorded well outside their normal range, and Rose-bellied and Orange-breasted Buntings are absent seasonally in some parts of Chiapas, in Mexico.

Glaucous-blue and Ultramarine Grosbeaks are partial austral migrants. The Yellow Grosbeak is a summer visitor in the northern part of its range, and has wandered repeatedly to southern Arizona. The Black-backed Grosbeak may be a partial or altitudinal migrant in some parts of its range, but its movements are not well understood. On the Caribbean slope of Costa Rica, the Black-thighed Grosbeak is an altitudinal migrant, moving from higher-lying forest to lower elevations in numbers varying from year to year, probably in response to variations in food abundance.

Although Northern Cardinals and Pyrrhuloxias do not migrate, both species gather in flocks during the winter months, and introduced Northern Cardinals appear to have spread through the Hawaiian Islands at least partly under their own volition (see Relationship with Man). Black-headed Grosbeaks, Blue Grosbeaks and Varied and Painted Buntings are migratory over much of their range, but their breeding and wintering areas overlap, and southern populations may be sedentary. Southern populations of the Black-headed Grosbeak may shift altitudinally. In contrast, Rose-breasted Grosbeaks, Indigo and Lazuli Buntings and Dickcissels are complete migrants, leaving their northern breeding areas in autumn for wintering grounds in Middle America and, for Rose-breasted Grosbeaks and Dickcissels, South America. Indigo Buntings from Michigan may travel 2900–4000 km to reach their winter quarters.

Black-headed and Blue Grosbeaks, Lazuli Buntings and western populations of Painted Buntings are moult migrants (see Morphological Aspects). In the autumn, they largely transfer to staging areas in the south-western USA and north-western Mexico, where they moult before completing the journey southwards to the wintering grounds.

Migratory species breeding in eastern North America, namely the Rose-breasted Grosbeak, eastern populations of the Blue Grosbeak and Indigo Bunting, and Painted Buntings from the Mississippi Valley and Gulf Coast, cross the Gulf of Mexico, although some Rose-breasted Grosbeaks fly around the gulf through north-eastern Mexico. Indigo Buntings flying northwards over the Gulf of Mexico in spring stop to feed along the southern coast of the USA before continuing on to their breeding areas.

Western species and western US populations of more widespread cardinalids migrate over land, though Lazuli Buntings appear on offshore islands in California during passage. Western migrants may still have to cross substantial barriers. As an example, Black-headed Grosbeaks crossing the Mohave Desert in autumn must cross 800–1100 km of desert terrain.

Lazuli and Indigo Buntings migrate along a broad front, rather than following mountain ridges. Indigo Buntings apparently fly downwind during the spring migration, both while crossing the Gulf of Mexico and while flying over land, and wind direction may influence the route that they follow.

Rose-breasted Grosbeaks and Indigo Buntings have broad breeding ranges in North America, and the extent to which eastern and western breeders mix on the wintering grounds is not entirely known. Ringing records suggest that eastern Rose-breasted Grosbeaks winter in Panama and northern South America, while more westerly ones spend the non-breeding season in Mexico and western Central America. Individuals from Ontario and New England have been recovered in western Central America, however, so it is evident that some mixing of populations does occur. The situation is similar for the Indigo Bunting, eastern and mid-western populations of which apparently follow parallel migration tracks and winter in separate areas. Indigo Buntings have been recorded as wintering in good numbers in Jamaica since the 1950s, this possibly representing a recent invasion of the island, as earlier observers failed to record them. One individual recovered in Jamaica had been ringed in Pennsylvania, in the eastern USA.

Eastern populations of the Painted Bunting migrate mostly to Florida and to a limited extent to the Gulf Coast, the Bahamas

and Cuba. More westerly breeders winter in Mexico and western Central America. Eastern Painted Buntings apparently show strong site-tenacity on their wintering grounds, the same individuals being trapped year after year in the same localities.

So far as is known, cardinalids generally migrate by night, although Black-headed Grosbeaks have been recorded moving by day in the Mohave Desert, and Lazuli Buntings may make short-distance movements during the day after arriving on the breeding grounds. Indigo Buntings depart on migration flight at night, but sometimes continue to fly into the daylight hours. In mid-April, ffrench observed groups of up to a hundred Dickcissels as they departed after dark, one after another, from their roosts in Trinidad. Departures continued for several nights until the roosts were empty. At other times during the wintering season, the birds did not leave their roosts at night after settling unless they were threatened by fire.

While migrating, cardinalids travel singly or in mixed-species or single-species flocks. Flocks of more than 50 migrating Rose-breasted Grosbeaks have been recorded in Panama, and J. Van Tyne recorded Indigo Buntings gathering in flocks in Guatemala during the weeks before they left to cross the Gulf of Mexico.

Spring migration is generally less protracted than that in autumn, probably because there is an advantage in securing territories and mates for adults that arrive early on the breeding grounds. There may, nonetheless, be considerable variation in the timing of spring migration among Indigo Buntings. Rose-breasted Grosbeaks have been estimated to migrate at an average rate of 80 km per day in spring and 38 km per day in autumn, including stopovers. The travel speed of migrating Indigo Buntings has been estimated at about 32 km per hour. Spring "overshoots", in which individuals occur far north of their normal breeding range in early spring, have been recorded for Blue Grosbeaks and Painted Buntings.

As is typical for North American passerines, males of migratory species tend to arrive on their breeding grounds ahead of the females, and older males before younger ones. The difference may be a matter of only a few days. Mean passage dates of Rose-breasted Grosbeaks captured on spring migration at Prince Edward Point, in Ontario, were 15th May for adult males and 18th May for yearling males and females. More brightly coloured yearling males tended to arrive earlier than dull-coloured birds.

Adult male Black-headed Grosbeaks arrive on their breeding grounds in New Mexico within 4–5 days of one another, while females start to arrive 5–7 days after the arrival of the first males. Yearling males reach the area some time later, 12–16 days after the first adult males and well after all adult males have settled, thereby avoiding the adults' peak period of aggressiveness. Unlike the Ontario Rose-breasted Grosbeaks, there is no apparent tendency for yearling males with more adult-like plumage to arrive earlier.

Lazuli Bunting males begin arriving in Utah, in the western USA, about four days before females and older birds two or three days before yearlings, although there is considerable overlap. There can be a gap of up to two weeks between the arrival of the first male Indigo Bunting and that of the first female, this apparently resulting from differences in pre-migratory fattening schedules and in times of leaving the wintering area. The average departure date recorded for males of all age-classes wintering in Jamaica was 16th April and that for females was 23rd April, a difference of a week. Arrival dates of Painted Buntings are less precisely known, but males were present in South Carolina one week before females and, in Georgia, adult males arrived 1–2 weeks before the arrival of yearlings.

The timing of autumn departure may also be staggered according to age and sex. Adult male Black-headed Grosbeaks leave the breeding grounds in late July or early August, but females and young of the year remain for several weeks longer, usually departing in mid-August. Adult male Lazuli Buntings leave their breeding grounds slightly before the females, and older birds slightly before younger ones, with juveniles of the year the last to depart. Adult males from the eastern population of Painted Buntings arrive on the wintering grounds in Florida before the females.

Prior to autumn migration, most Indigo Buntings increase their mass by some 50% as they accumulate subdermal and abdominal fat deposits. Those that do not do so may stop to feed en

*The male **Painted Bunting** apparently does not feed the nestlings and only sporadically visits the nest while the young are in it. The female brings them caterpillars, small grasshoppers (Orthoptera) and beetles (Coleoptera), which she gathers both on and off the male's territory. Females frequently brood between feeds, especially when the nestlings are small. The female may begin to construct a new nest for a second brood while still feeding fledglings. One was observed to feed a young bird, pull some material from a branch and place it in the new nest, then fly to fetch more food. But just before she begins egg-laying, the male takes over the feeding of the fledglings. The young begin to catch insects themselves at 26–29 days of age.*

[*Passerina ciris pallidior*, Kickapoo Cavern State Park, Texas, USA. Photo: Sid & Shirley Rucker/ DRK]

For a few cardinalid species, there are instances of more than one female laying in the same nest, and even of nests occupied simultaneously by more than one female. But the ***Northern Cardinal*** *has been known to share with some odder nestfellows, as these remarkable photographs show. This nest, which contained three cardinal chicks and four young* ***American Robins****, was found in Erlanger, in Kentucky, in the mid-1970s. It was not discovered (or not reported) until after the young had hatched, but the nest appears to have been begun by the cardinals and finished by the robins. It is not known how the birds shared incubation. The brood sizes were typical for each species, and all young fledged. The photographer recalls that the species seemed to tolerate each other, but were not enthusiastic friends. When the young first hatched, there seemed to be some cross-feeding between the species, perhaps out of confusion. As the young grew and became more distinct, and the parents became more familiar with the setting, the adults seemed to target their own young, helped by the fact that the interior of a robin's mouth is yellow, while the interior of a cardinal's is red. The same two species shared a nest in Iowa; the two females, attended by their mates, incubated the eggs separately or while sitting side by side on the nest, although only the robin chicks fledged successfully.*

[*Cardinalis cardinalis cardinalis* and *Turdus migratorius*, Erlanger, N Kentucky, USA.
Photos: Dave Maslowski/ Maslowski Productions]

route; in order to cross the Gulf of Mexico, a bunting will need to expend about 30% of its body mass. Indigo Buntings wintering in Jamaica take on fat prior to the northward return migration, but those in the southern part of the wintering range do not; presumably, the latter stop to build up their fat reserves in Mexico before re-crossing the Gulf. As the birds move northwards towards their breeding grounds, they stop to feed, but they arrive leaner than they become later in the season.

Dickcissels gain extra fat prior to autumn migration both by eating more and by increasing their digestive efficiency so that fewer nutrients are lost in their excreta. In late March and April, the birds become hyperphagic on their wintering grounds, "overeating" in order to gain fat reserves. Metabolic adjustments allow them to put on fat more rapidly than those individuals whose gain in mass is due to food intake alone. Dickcissels wintering in Trinidad may increase their weight by 56%. These behavioural

and physiological shifts appear to be controlled by internal mechanisms, and will continue for at least a year even if the birds are kept in controlled environments with constant daylength and temperature.

In the 1960s, Emlen carried out studies of migratory orientation by Indigo Buntings and a single female Rose-breasted Grosbeak that exhibited migratory restlessness ("Zugunruhe"). Both species were able to orient themselves in the appropriate direction when exposed to the night sky. In experiments in a planetarium with captive Indigo Buntings, the birds oriented themselves in the appropriate direction as indicated by the sky projection, but they were unable to orient if no projection was shown. These results supported the hypothesis that the birds steer primarily by the patterns of stars in the night sky. Further experiments revealed that the buntings were able to adjust for stellar rotation as the nights progressed, suggesting that they have an internal clock that allows them to compensate for shifts in time.

Other mechanisms, however, must also be involved in migratory orientation. Emlen and his colleagues demonstrated in further experiments that, even when the night sky was visible, alteration of the magnetic field caused captive Indigo Buntings to shift direction. P. D. Sniegowski and his colleagues captured adults of this species in summer, and in the following spring released them some 1000 km from the capture site. The birds were able to return to their former breeding sites and reclaim their territories, suggesting that experience with familiar landscape cues may be important in informing them that they have arrived at their destination.

A few species have been recorded straying to Europe, for instance the Indigo and Lazuli Buntings and the Dickcissel. Much the most significant is the Rose-breasted Grosbeak, which may be the third commonest transatlantic vagrant among all the passerines.

Finally, with regard to the two probably non-cardinalid genera *Parkerthraustes* and *Saltator*, neither the Yellow-shouldered Grosbeak nor any species of *Saltator* is migratory, although some saltators are known to wander. In Ecuador, the Masked Saltator undertakes non-seasonal movements, perhaps in response to changes in the availability of cones of *Podocarpus oleifolius* (see Food and Feeding).

Relationship with Man

Cardinalids have attracted human attention, and admiration, for centuries. This is reflected in some of their local names. For example, in South America, the Black-backed Grosbeak is known as *rey del bosque*, meaning "king of the woods", while *Cyanocompsa* and *Cyanoloxia* grosbeaks are known as *reinamora*, or "gypsy queen", the Ultramarine Grosbeak being *reinamora grande* while the Glaucous-blue Grosbeak is *reinamora chica*.

Northern Cardinals have become human commensals in many areas. They are common and popular year-round visitors to suburban feeding stations, where, as M. M. Nice put it in 1927, "they rejoice us with their flaming beauty and their splendid song". At the other extreme, Black-backed Grosbeaks are reportedly killed by some fruit-growers, who regard them as a pest.

The Dickcissel has been hunted for food and heavily persecuted as a crop pest in Venezuela, where it is known as *el pájaro arrocero*, "the rice bird" (see Food and Feeding, Movement, and Status and Conservation). Hunters shoot these birds with guns and slingshots, enter their roosts at night and club the birds with sticks and bats, and even drive vehicles rapidly through flocks flying low across farm roads. In 1963, in Mexico, an unusual concentration of millions of Dickcissels near the city of Culiacán, in Sinaloa, wrought havoc on local wheat crops, and the farmers responded with firearms, explosives, slingshots, sticks and huge quantities of pesticides.

Cardinalids were well known to native Americans. A Yanomamo tale mentions that Yellow-green Grosbeaks eat hayi (*Pseudolmedia laevigata*) fruits. In the late sixteenth century, the artist and colonist John White recorded, on a watercolour, the Algonquian name *Meesquouns* for the Northern Cardinal in North Carolina.

Cherokees invoked the Indigo Bunting to control the wind, possibly because of its blue colour, as they called upon the East-

*Both **Northern Cardinal** parents generally carry away the nestlings' faecal sacs, although in the first days after hatching the adults swallow these rather than removing them. Nests can become infested with mites (Acarina) and other invertebrates, which may be one reason why subsequent broods are normally raised in a new nest. During 1960, in Canada, 534 organisms were collected from 32 Northern Cardinal nests in London, Ontario. In order of decreasing numbers they were ants, bark lice (Psocoptera), beetles, mites, sowbugs (Isoptera), springtails (Collembola), spiders, snails, millipedes (Diplopoda), harvestmen (Opiliones), hemipterous nymphs, biting midges (Diptera), a slug, a damsel bug (Nabidae) and a wasp.*

[*Cardinalis cardinalis cardinalis*, SW Ohio, USA. Photo: Dave Maslowski/ Maslowski Productions]

Saltators typically fledge at around twelve days and leave the nest at 13–15 days, although this may vary. The nestling period for the ***Greyish Saltator*** *in Argentina appears to be 18–19 days, whereas a Streaked Saltator* (Saltator striatipectus) *chick was fully fledged by eleven days and left the nest at 13 days. During the first few weeks out of the nest, young saltators remain in dense cover and continue to be fed by the parents. Fledglings of the Buff-throated Saltator* (S. maximus) *are attended by both parents until they are 50–55 days old.*

[*Saltator coerulescens coerulescens*, Kuryala Lodge, São Felix do Araguaia, Mato Grosso, Brazil. Photo: Edson Endrigo]

ern Bluebird for the same purpose. Cherokee men invoked the Northern Cardinal, the "Redbird", as part of a spell to attract women, as transcribed some time after 1890:

I am dressed as well as the Redbird
I am as handsome as the Redbird
I am as masculine as the Redbird
I can do as much as the Redbird
I can say as much as the Redbird
Dho tsu! Dho tsu hwi!

The Cherokees believed that the Northern Cardinal was the daughter of the sun. According to a Cherokee legend, the cardinal was originally a brown bird, but, after he had helped a wolf to clear mud from his eyes—mud placed there by a trickster raccoon—the wolf rewarded him by painting his feathers red with pigment from a magical rock. In a variant of the story, the bird jumped into a magical pool, being careful not to submerge his mouth, which is why there is no red around the cardinal's beak. By the time his mate arrived, there was enough red paint left only to daub her in a few places, leaving her barely touched with red to this day.

Cardinals have been regarded as omens. Some southern native Americans believed that the sudden flight of a cardinal foretold the arrival of a guest. There is also a superstitious belief that a cardinal flying up is a sign of good luck, but one flying towards the ground is a portent of ill fortune.

The Northern Cardinal has been chosen as the state bird of seven American states, starting with Kentucky, in 1926, and followed by Illinois, after a poll of the state's schoolchildren, and Ohio, North Carolina, West Virginia, Virginia and Indiana. The bird has given its name to a number of sports teams, including the St Louis Cardinals baseball team.

Northern Cardinals have been kept in Europe since the sixteenth century. An account entitled "De Coccothrauste Indica cristata", accompanied by a woodcut apparently drawn from life, was published in 1600 in *Tomus Alter* of the *Ornitologiae* of U. Aldrovandi (1522–1605). Even then the bird was known as *cardinalitus*, presumably, as Aldrovandi notes, because of its red colour, the hue associated with ecclesiastical cardinals. Aldrovandi passes on a report that a living specimen ate almonds and chickweed, became agitated on seeing its reflection in a mirror, plunged itself into water frequently, and imitated the voices of other birds, particularly the Common Nightingale (*Luscinia megarhynchos*). In 1731, M. Catesby noted that the bird was known in England as the "Virginia Nightingale", and was popular in Europe for its "beauty and agreeable singing".

The Painted Bunting has long been known in aviculture as the *Nonpareil*, a word meaning "without equal". According to Audubon, even in the early nineteenth century large numbers were trapped in Louisiana for the cagebird trade. People used a mounted male as a lure to catch the birds; a passing male Painted Bunting "dives towards the stuffed bird, with all the anger its little breast can contain. It alights on the edges of the trap for a moment, and throwing its body against the stuffed bird, brings down the trap, and is made prisoner." The birds were bought by middlemen for sixpence in New Orleans, but on arrival in England they fetched three guineas each in London. Few vessels left New Orleans in the summer months without carrying some Painted Buntings. Painted Buntings continue to be extensively trapped on their wintering grounds (see Status and Conservation).

All except one of the *Passerina* buntings are kept and bred in Europe. The single exception is the Rose-bellied Bunting, which apparently has never been imported into Europe, a rather surprising fact when one considers that the Orange-breasted Bunting, even though it has proven a difficult species to breed, is well known in trade.

Other members of the family commonly kept as cagebirds include the Ultramarine and Glaucous-blue Grosbeaks, the Vermilion Cardinal and the Green-winged Saltator (see Status and Conservation).

Status and Conservation

None of the species presently included in the family Cardinalidae is currently considered to be globally threatened, but four are listed as Near-threatened. These are the Painted Bunting, the Rose-bellied Bunting, the Masked Saltator and the Rufous-bellied Saltator. Although not classified as globally threatened, the Black-throated Saltator, a *cerrado* endemic, is listed as "Vulnerable" in the state of São Paulo, in Brazil. In the 2007 WatchList published

After having left the nest, ***Northern Cardinal*** *fledglings may move very little for up to eleven days. They can fly by 19 days of age. One juvenile Northern Cardinal in Maryland, USA, was independent by 50 days, but associated with its parents for a further 20 days. The juvenile's plumage is similar to the female's, but much duller, although males can have some red on the chest or flanks. The bill is greyish. Early-hatched young of this species often undergo a complete moult, but late-hatched cardinals may retain their first flight-feathers during the winter.*

[*Cardinalis cardinalis cardinalis*, New York, USA. Photo: Marie P. Read]

by the National Audubon Society and the American Bird Conservancy, Varied and Painted Buntings are listed in the "Yellow category", indicating that they are declining or rare.

The Masked Saltator is known from only a few disjunct localities in the central Andes of Colombia, southern Ecuador and north-central Peru, where it is rare and local (see Habitat, and Food and Feeding). L. M. Renjifo has suggested that its low population density in Colombia may be the result of its strong preference for highly localized patches of *Podocarpus oleifolius*, a slow-growing primary-forest tree that has been overcut for its valuable wood. The species' known localities in Colombia and Ecuador are in heavily deforested areas, and in general the montane forests of the north Andes are under intense threat from conversion to agriculture and cattle pasture, mining and logging.

In addition to its global Near-threatened status, the Masked Saltator has been listed as "Vulnerable" in Colombia. Its most viable populations may be in Podocarpus National Park, in southern Ecuador, and in the Alto Quindío Acaime Natural Reserve–Los Nevados National Park–Ucumari Regional Park complex, in Colombia. Deforestation in the south-eastern buffer zone of Podocarpus National Park is expected to eliminate half of the remaining *Podocarpus* in the years to come.

Cowbirds (Molothrus) *may be particularly attracted to the* ***Northern Cardinal*** *because its bright colours and conspicuous behaviour make its nests easier to find. But the presence of young cowbirds in the nest seems to have little effect on the cardinal's young, with no significant differences in weight and size between nestlings in parasitized and unparasitized nests. Other species do not fare so well. Pyrrhuloxias* (Cardinalis sinuatus) *in Texas fledge very few young if they have been parasitized.*

[*Cardinalis cardinalis magnirostris*, New Braunfels, Texas, USA. Photo: Rolf Nussbaumer/naturepl.com]

*Post-breeding flocks of **Dickcissels** move into areas of high food abundance, where they gain weight both by eating more and by increasing their digestive efficiency. Prior to migration, they may accumulate up to 15 g of fat. Travelling mostly at night, they arrive on their core wintering grounds in Venezuela in September or October. In late March and early April, after dark, groups of Dickcissels break away from the huge roosting flocks and begin their return migration together. These departures continue for several nights until the roosts are empty. Dickcissels are erratic and invasive, and numbers in different areas of their breeding and wintering grounds can vary dramatically from year to year.*

[*Spiza americana*, Port Aransas, Texas, USA. Photo: Andy & Gill Swash/ WorldWildlifeImages.com]

The Rufous-bellied Saltator of the Andes of Bolivia and north-west Argentina is thought to have a relatively small, fragmented population containing in excess of 10,000 individuals, and to be in decline owing to loss of its temperate shrubland habitat. It is very local outside the Bolivian province of Cochabamba, where it is common in some areas, but it is common in one area in La Paz, and it has recently been found at several new sites. Native shrub species may be essential to its survival, but shrubland patches, including *Polylepis* and alder (*Alnus*) stands, in its range are being fragmented and converted for agricultural and commercial forest use.

The little-known Rose-bellied Bunting is considered Near-threatened on the basis of its restricted Mexican range. Habitat degradation, including forest fragmentation, has been occurring within its area of distribution, but the effect of this on the species is at present unclear. In Mexico, this bunting is classified as "Threatened".

With a seemingly healthy global population, estimated at 4,500,000 in 2011, the Painted Bunting is still common in some areas. Nonetheless, there is evidence that it declined rapidly throughout its range from the mid-1960s until at least 2004–2005. North American Breeding Bird Survey data showed a significant decline of about 2·5% annually between 1966 and 2002 in the continental USA (including five years of data from north-eastern Mexico), amounting to a total loss of roughly 55% of the original population. National Audubon Society Christmas Count data from 1960 to 2003 also demonstrated a population decline. This decline has been blamed on habitat degradation and loss, cowbird parasitism in the case of the eastern population, and heavy trapping on the wintering grounds for the pet trade. Development of coastal swamp-thickets and woodland edges, loss of stands of shrubby wax myrtle (*Myrica*) and buckthorn (*Rhamnus*) in open-canopied pines and hardwoods, and replacement of native grasses, the seeds of which are an important food source, with sod grass have significantly reduced available habitat in the limited coastal range of the eastern population. Loss of riparian habitat in the south-western USA and in north-western Mexico affects the western population's mid-migratory staging and moulting areas. Brown-headed Cowbirds have only recently expanded into the breeding range of the eastern population, where parasitism rates now reach as high as 80%.

Although protected by law in the USA, Painted Buntings have been trapped legally in Mexico for at least the last 50 years. One probably conservative estimate suggests that, between 1979 and 2002, up to 5800 individuals each year—a minimum total of 100,000 overall—were legally trapped in Mexico for the domestic pet trade alone. In the 1984–1985 harvest season, trappers for the domestic trade were authorized to harvest 23,000 birds in five Mexican states. Painted Buntings have also been reported in local markets in Cuba, Costa Rica, Nicaragua and Guatemala, and illegal trade in the species has been reported in both Mexico and Florida.

In addition to capture for domestic markets, Painted Buntings have been trapped for export to markets in Europe, Asia and South America. The UK, Belgium, the Netherlands, Greece, Italy, Spain, Malaysia, Japan, Argentina and Paraguay have been recorded as major importers of the species. Painted Buntings reportedly fetch US$70 per pair on Asian and European markets. Except during the years 1982–1999, when it banned wildlife exports, Mexico has exported large numbers of the birds. Export figures reached at least 15,000 individuals during the 1974–1975 harvest season, and an estimated 12,000 during 2001–2002. In 2004, Mexico and the USA proposed that the Painted Bunting be included on Appendix II of the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES), but the proposal was not accepted.

Several other cardinalids are trapped in varying numbers. Ultramarine Grosbeaks are common targets of cagebird-hunters in Brazil, where there is extensive illegal domestic traffic in wild birds. They were among the species most frequently confiscated from bird-traffickers in Rio Grande do Sul, in south-east Brazil, between 1998 and 2000. In Catolé do Rocha, a city in Paraíba, in the *caatinga* region of Brazil where native bird-keeping is particularly common, a 2006–2007 survey of cagebirds in markets and private homes found Ultramarine Grosbeaks to be the sixth-commonest out of 38 species recorded. During 2006, Green-winged Saltators and Ultramarine Grosbeaks were the third and sixth most frequently confiscated bird species, with 2730 and 916 individuals, respectively, in the Brazilian state of São Paulo. Glaucous-blue Grosbeaks have also been popular targets, as have some other saltators. Numbers of Golden-billed Saltators in Córdoba,

*The **Vermilion Cardinal** is a restricted-range species found in the Caribbean Colombia and Venezuela Endemic Bird Area (EBA), in the north of those countries. It is quite common in semi-arid scrub with cacti and spiny leguminous bushes, and is not considered globally threatened. Large areas of suitable habitat remain in both countries, but are almost entirely unprotected. The Vermilion Cardinal is frequently captured illegally for the cagebird trade, and uncontrolled poaching can have a marked negative effect on populations. The species' long-term survival may depend on the protection of sites where poaching is not yet a problem.*

[*Cardinalis phoeniceus*, La Guajira, Colombia. Photo: Pete Morris]

in Argentina, are reportedly dwindling owing to the capture of adults for pets, as well as high nest predation in rural areas.

In northern Venezuela, the Vermilion Cardinal is a target for poachers. Rodríguez-Ferraro found that populations at three of six arid-zone sites studied in 2004–2005 had been reduced as a result of illegal trapping for the cagebird trade. The species' long-term survival may depend on the protection of sites where poaching is not yet a problem.

Although the Varied Bunting is apparently expanding its range in Arizona, and its global population has been estimated at 500,000–5,000,000 individuals, it has become a rarity in southern Texas and is listed as "Threatened" in New Mexico, where it has only recently established itself, breeding having been first recorded in 1972. This species' habitat may be threatened by development along the USA–Mexican border and over much of its Mexican range.

Currently classified as of Least Concern by IUCN, the Dickcissel has been the subject of considerable conservation attention in the past. One observer even predicted in 1979 that the species would be extinct by the year 2000. In some part this concern has been the result of a failure to appreciate the species' opportunistic colonization and breeding strategies. Dickcissels are erratic and invasive, and they can appear for a short time in areas not suitable for long-term colonization. Those that invaded the central Canadian province of Manitoba in 1973, for example, nested in alfalfa fields but, when the fields were cut, any nests with young were presumably destroyed.

During the first half of the nineteenth century the Dickcissel was common along the eastern seaboard of the USA from Cape Cod south to the District of Columbia, but by 1904 it had completely disappeared as a breeding species east of the Allegheny Mountains, in the west-central Appalachians. This disappearance has never been satisfactorily explained, although it is possible that the eastern population represented a recent colonization, sustained by the spread of hay crops in the region. It was suggested at the time that the increased use of mowing machines during the nesting period might have been responsible, but S. N. Rhoads had pointed out in 1903 that these machines were used also in the western part of the species' range. Rhoads suggested that the birds had not disappeared at all, but that the eastern breeders had simply shifted to the west, possibly as a result either of some event on the wintering grounds or of meteorological changes along the spring migration route.

Whatever the true explanation, Dickcissels began to reappear in the east in the 1920s. In 1928 they staged an extensive eastern invasion, turning up in the area from New Jersey south to South Carolina, but the species failed to re-establish itself as more than an occasional straggler and sporadic nester.

Whether these shifts were accompanied by a genuine change in numbers remains unclear. By the mid-1960s, however, Dickcissel populations began to decline in earnest. The North American Breeding Bird Survey recorded a 40% continent-wide drop in numbers between 1966 and 1996, although the population appears to have stabilized to some extent by the mid-1990s.

*The **Masked Saltator** is one of four cardinalids categorized as Near-threatened. Patchily distributed in steep montane forest in Colombia, Ecuador and Peru, this saltator is nowhere common and is thought to be in decline because of habitat loss. Recent studies suggest a strong association with the tree* Podocarpus oleifolius, *which comprises a very small proportion of montane evergreen and elfin forest.* Podocarpus *is slow-growing and heavily logged for its wood.*

[*Saltator cinctus*, above Ibague, Colombia. Photo: Hadoram Shirihai]

*The **Black-cowled Saltator** is a restricted-range species, confined to less than 20,000 km² of humid montane forest and forest edge in the Tumbesian Endemic Bird Area (EBA) of western Ecuador and north-western Peru. During the late 1980s this species was listed as Near-threatened, but, because it is now known to be able to adapt to degraded habitats and regenerating scrubland, it is currently considered of Least Concern. But less than 5% of the primary forest in the Tumbesian EBA remains, and 15 of the more forest-dependent restricted-range species found there are listed as globally threatened.*

[*Saltator nigriceps*, Utuana, Loja, Ecuador. Photo: Doug Wechsler/ VIREO]

Data from this ongoing survey indicate that the overall decline has slowed to insignificant levels in recent years, and in 2007 the species was removed from the National Audubon Society's Watchlist for United States Birds.

Nevertheless, decline is still continuing at regional levels. Dickcissel populations in restored grasslands in Missouri and Iowa are not self-sustaining. R. J. Fletcher and his colleagues found rates of decline in Iowa to be approximately 40% per year, nest predation being the largest contributing factor (see Breeding). Similarly, in a study published in 2008, K. With and her colleagues found that Dickcissel populations in the Flint Hills of Kansas and Oklahoma, an area that preserves the largest intact tall-grass prairie (about 2 million ha) left in the world, are continuing to decline at an estimated annual rate of either 11–21% or 19–29%, depending on the analysis.

Dickcissels adapt better to changes in land use than some other grassland species, such as Henslow's Sparrow (*Ammodramus henslowii*), although they are less productive than Henslow's Sparrows in prairie fragments in south-western Missouri. Studies of nesting success failed to locate evidence connecting their fall in numbers to conversion of original prairie habitat to agricultural land. The primary factor in the Dickcissel's decline in the second half of the twentieth century appears to have been persecution by farmers on the wintering grounds in Venezuela, where the species is perceived to be a serious crop pest (see Food and Feeding).

S. D. Fretwell suggested that the decline may have been related to a skewed sex ratio, brought about because male Dickcissels, which are larger than females, were better able to feed on the large seeds of cultivated rice and sorghum. He predicted that the population would come to be dominated by males, and that this could lead to the collapse of the species. Basili and Temple found a sex ratio on the wintering grounds of 1·53 males to 1 female, much lower than Fretwell had predicted, and they were unable to establish either that this was due to female starvation or that it had changed significantly since the 1960s.

Instead, Basili and Fretwell blamed much of the decline on direct persecution. Most efforts by Venezuelan farmers to prevent crop damage in the weeks preceding the harvest involve noise-making, people either banging pots and pans in the fields or shooting air cannons or bottle-rockets. Some, however, use organophosphates such as parathion and azodrin to poison water-holes, spray feeding areas just prior to morning feeding bouts, and spray nocturnal roosts from the air or the ground. Spraying of nocturnal roosts in particular sometimes kills hundreds of thousands of birds in minutes. One farmer estimated that he had killed more than 1,000,000 birds on his property over the years.

Although the use of lethal control methods appears to have declined in recent years, Dickcissels are still vulnerable on the wintering grounds. A single roost, which could be destroyed in a few nights, can contain up to 3,000,000 million individuals, 30% of the species' entire global population. Alternative, non-lethal control methods, in addition to simply frightening the birds away, could include the use of repellent chemicals such as methiocarb and anthraquinone. Trials of these chemicals on captive Dickcissels reduced the birds' consumption of rice by between 70% and 90%. In 1998, the Venezuela Audubon Society held a

*The forests of the Costa Rica and Panama Highlands Endemic Bird Area (EBA), where the **Black-thighed Grosbeak** is found, have suffered widespread destruction. In Costa Rica, it is predicted that the forests will not long survive outside protected areas, and in Panama only isolated patches are left. The Black-thighed Grosbeak is still fairly common in Costa Rica, but local or uncommon in Panama. As well as being present in many protected areas, however, it can adapt to heavily degraded forest and other modified habitats such as pastures with residual trees. It is not considered globally threatened.*

[*Pheucticus tibialis*, San Gerardo de Dota, Costa Rica. Photo: Marco Saborío]

A restricted-range species present in the High Andes of Bolivia and Argentina Endemic Bird Area (EBA), the ***Rufous-bellied Saltator*** *is largely associated with* Polylepis *forest. In Bolivia, it is still common at some sites in Cochabamba, but is otherwise very local. Several new sites have been discovered, and the total Bolivian population is thought to exceed 10,000. In Argentina its status is uncertain; it seems generally uncommon and has disappeared or declined in areas where it was previously abundant. Although sometimes found in agricultural fields, it may depend on access to patches of native shrubs and trees. It is considered Near-threatened because of its fragmented and declining population.*

[*Saltator rufiventris*, Tunari National Park, Cochabamba, Bolivia. Photo: Daniel Alarcón]

workshop on the matter, and this resulted in the formation of a Ricebird Alliance, led by the society and the region's two most important farmers' groups, intended to find co-operative ways to address the problem.

In contrast to the efforts made to remove species from sensitive areas, there have been several attempts to introduce cardinalids in places outside their natural ranges. European settlers introduced Northern Cardinals into Bermuda, probably from Virginia, perhaps as long ago as 1700, but certainly by the early nineteenth century. Thousands were reportedly trapped there for the cagebird trade during the nineteenth century. J. M. Jones, who apparently thought that the birds arrived in Bermuda naturally, reported in 1859 that a "favourite sport of native boys" was to catch cardinals with traps made from lantana stems and baited with maize. The species is still common in Bermuda, despite a reduction in numbers since the 1950s following increased urbanization, the loss of native cedar (*Juniperus bermudiana*) forest and the introduction of House Sparrows (*Passer domesticus*), Common Starlings (*Sturnus vulgaris*) and Great Kiskadees (*Pitangus sulphuratus*).

Cardinals, including individuals from a mixture of races, have been repeatedly introduced into south-western California since 1880, but have failed to spread. They were introduced in Victoria, in Australia, without success in the 1860s or 1870s. Cardinals were released on Tahiti at some point after 1921 and were common there for a time, but the species had apparently disappeared by 1972. In the Hawaiian Islands, Hui Manu and other acclimatization societies released 300–350 Northern Cardinals on Kauai, Oahu and Hawaii between 1929 and 1931. As part of a "Buy-a-Bird" campaign during 1929–1930, schoolchildren in Hilo, on Hawaii, were encouraged to raise money to bring 163 cardinals to the island from Oahu. The birds were well established in the archipelago by the end of the 1930s, and subsequently spread, apparently unassisted, to Maui by 1943, Niihau by 1947, Molokai by 1951, Lanai by 1957, Kahoolawe before 1980 and, surprisingly, Nihoa, at least 275 km from the nearest source island, by 1983.

Attempts were made in the 1930s and 1940s to introduce *Passerina* buntings in Hawaii. On Oahu, Indigo Buntings were released during 1934–1936 and Painted Buntings before 1937, by Hui Manu, and more than 425 pairs of Orange-breasted Buntings were released in 1941–1950; Orange-breasted Buntings were brought to Maui in the 1940s; and Indigo and Painted Buntings were released on the island of Hawaii in May 1937. Although Orange-breasted Buntings did breed on Oahu in 1950, none of these attempted introductions was successful. Grosbeaks, possibly Black-headed, were released, likewise unsuccessfully, at Pu'u Wa'a Wa'a Ranch, on Hawaii, in 1902.

Although habitat fragmentation can have a highly detrimental effect on nesting cardinalids (see Breeding), the members of this family often appear to adapt well to disturbed habitats and human presence. For example, Black-thighed Grosbeaks are common in human-dominated landscapes in Ecuador. Blue-black Grosbeaks more than doubled their numbers in burnt forest plots 10–15 months after an accidental understorey wildfire swept through the Tapajós–Arapiuns Extractive Reserve in central Brazilian Amazonia in 1997, although the same species disappeared from *terra firme* forest fragments 1 ha in size, though not from larger ones, at the Biological Dynamics of Forest Fragments Project (BDFFP) near Manaus.

The effects of human activity on cardinalids may be more subtle. T. M. Jones and his colleagues have recently demonstrated that the plumage brightness of male Northern Cardinals in Ohio is lowered in areas of increasing urbanization, although the birds can compensate for this in more urban areas by feeding on the carotenoid-rich fruits of ornamental plants such as Amur honeysuckle (*Lonicera maackii*).

A number of species in North America have expanded their ranges following human alteration of the landscape. During the 1980s, after severe frosts killed thousands of acres of citrus groves in central Florida, the abandoned groves became overgrown with weedy vegetation. This converted them into ideal breeding habitat for Blue Grosbeaks and Indigo Buntings, and these species have substantially increased their breeding range in the state. Painted Buntings have undergone a similar but more limited increase.

The Northern Cardinal has achieved a considerable northward range expansion since the nineteenth century, the probable result of warming climate trends, increases in edge habitat created by human alteration of the landscape, and the popularity of winter feeding stations. The cardinals may have followed river valleys as they moved northwards, although they are not confined to riparian habitat in core areas of their range.

Northern Cardinals were first recorded in Ontario in 1849, in South Dakota in 1887, in Michigan in 1884 and in Minnesota in the

late nineteenth century. They invaded Wisconsin in 1900 and again, more successfully, in 1910–1912, 1919–1920, 1927–1928 and 1932–1935, each invasion carrying them farther north in the state. They expanded "spectacularly" in New England during the 1950s. Cardinals expanded their range in Canada throughout the twentieth century, particularly after the late 1930s. They are now abundant residents in southern Ontario, having reached Ottawa, Sudbury and Thunder Bay by 1976. The species has also expanded its range in the south-west USA, spreading through the Colorado River Valley in Arizona and, marginally, south-eastern California.

Currently considered Near-threatened, the ***Painted Bunting*** *is classified as "Declining" in the USA. Breeding Bird Survey data from continental USA indicate a decline of 55% over the 30 years to 1996, with the steepest declines (75%) in the eastern, nominate race. The reasons for its decline are not clear, but are thought to be related to loss of habitat, including the more aggressive control of brush along highway verges and the construction of golf courses. Painted Buntings are also trapped in large numbers on their wintering grounds for the cagebird trade. Declines in both races may be slowing, however, and this species, like other* Passerina *buntings in the USA, is extending its range.*

[*Passerina ciris pallidior*, Sinton, Corpus Christi, Texas, USA. Photo: Bill Draker/ ImageBroker/FLPA]

*The **Rose-bellied Bunting** is still fairly common within the Isthmus of Tehuantepec Endemic Bird Area (EBA), in southern Mexico, but its global range amounts to just 7000 km². Its area of occupancy may be even smaller: in La Sepultura Biosphere Reserve, which covers most of the Chiapas part of the EBA, less than 20% of habitat was found to be suitable for it. The global population, estimated at fewer than 50,000, could be declining because of habitat degradation and fragmentation. Currently listed as Near-threatened, the Rose-bellied Bunting's threat status may be raised if the potential threats to its habitat are judged to be serious. This would make it the first member of its family to be considered globally threatened.*

Genus *SPIZA* Bonaparte, 1824

1. Dickcissel

Spiza americana

French: Dickcissel d'Amérique **German**: Dickzissel **Spanish**: Arrocero
Other common names: Black-throated Bunting

Taxonomy. *Emberiza americana* J. F. Gmelin, 1789, New York, USA.
Has in the past been placed in New World blackbird family (Icteridae), and thought by some to be intermediate between that and New World sparrows (Emberizidae). Recent molecular-genetic studies support placement in present family. Monotypic.
Distribution. Breeds extreme S Canada and C & EC USA; migrates to Middle America and N South America.

Descriptive notes. c. 16 cm; male average 28·5 g during breeding, 36 g pre-migratory Apr (Venezuela); female 25 g during breeding, 30 g pre-migratory in Apr (Venezuela). Male breeding has crown greyish, strongly washed yellow in front, nape grey-brown, supercilium from bill to past ear-coverts bright yellowish at front, becoming duller posteriorly and near-whitish at rear; ear-coverts grey, broad submoustachial stripe yellowish at centre, otherwise white; chin and upper throat whitish; upperparts medium-brown to brown-grey, with heavy black streaks on feather centres, rump grey-brown, shoulder chestnut; flight-feathers blackish-grey, narrow brownish edgings on outer webs, carpal area yellow, tertials blackish-grey or blackish with broad buff-brown or chestnut-brown edgings on outer webs; greater upperwing-coverts brown, edged paler; rectrices dull brown, central tail feathers narrow and pointed; lower throat and central foreneck black, chest yellow with variable amount of black central spotting, spots often coalescing into larger, pointed black patch on upper chest; side of chest grey, suffused yellow, centre of upper belly yellow, becoming yellowish-white and then greyish-yellow on flanks; lower belly yellowish-white; iris dark brown; bill pale horn or bluish-grey with small black tip and variable black along culmen; legs flesh-brown to pinkish-buff. Male non-breeding has back suffused with brownish and the yellow less bright. Female is smaller than male, has black on throat reduced to two narrow malar streaks, chin and throat whitish, becoming yellowish on centre of chest; crown greyish-brown, supercilium and submoustachial stripe much less prominent than on male, back brown with broad blackish streaks. Juvenile is similar to female, but underparts buffier, and with two distinct pale wingbars; immature male differs from adult in having little black on chest, narrow submalar stripe, yellow on underparts much reduced, crown feathers brown with black centres and no yellow wash, supercilium much reduced. VOICE. Song onomatopoeic, a dry insect-like series of notes, e.g. "see see dick dick ciss ciss ciss" etc., the whole lasting c. 1·5 seconds. Call note a sharp "click"; flight call a buzzy "bzzrt", used by flock on migration.
Habitat. Grassland areas. Breeding habitats include hay fields, grassy roadsides, lightly grazed pastures and early fallow areas; prior to European settlement, native grassland prairies with good proportion of non-grass species. On wintering grounds various open areas, especially rice fields and grassland; requires secure areas for communal roosting, such as sugar-cane plantations or tall grass. Regular annual burning of grassland generally detrimental.
Food and Feeding. During breeding season omnivorous, stomach contents about two-thirds animal, one third vegetable. Prey includes grasshoppers (Orthoptera), caterpillars, flies (Diptera), spiders (Araneae), beetles (Coleoptera) etc.; vegetable matter largely various seeds. On migration mainly grass seeds; on wintering grounds mostly vegetable matter, including crops of rice and sorghum, also insects and spiders. Nestling diet arthropods, including e.g. beetles, caterpillars, grasshoppers, hymenopterans.
Breeding. Egg-laying begins mid-May in S parts of range (e.g. Texas) and Jun in N; single-brooded, although possible that some, after breeding, move to other areas and breed again. Male generally polygamous, success in attracting multiple partners related to quality of his territory; of 150 males in one Kansas study, 14% (mostly yearlings) had no mate, 36% monogamous, 41% bigamous, 9% had three or more mates, the most successful up to six. Males arrive on territory 5–10 days before females, pairing takes place quickly thereafter; in core areas male shows strong fidelity to nesting territories, presence of suitable nest-sites apparently a criterion of territory quality. Nest built entirely by female, male in attendance throughout early stages of breeding until about hatching time; loose cup of coarse weed and grass stems, with some leaves, lined with finer grasses, hair and rootlets, situated near (but not on) ground in dense vegetation of coarse grasses or low woody bush, height varying with type of supporting plant, usually 20–50 cm, occasionally much higher. Clutch 3–6 eggs, average 4, unmarked pale blue; incubation by female alone, period 12–13 days; chicks brooded and fed generally by female alone, male defends territory, in one Illinois study male played significant role in feeding of young; nestling period 8–10 days; fledglings attended by female for a further two weeks. Nests intensively parasitized by Brown-headed Cowbird (*Molothrus ater*), parasitism rates varying geographically and during course of year; early in season, in some areas, may be 100%, and frequently nests contain more cowbird eggs than host eggs; generally accepts cowbird eggs, but if too numerous (one nest contained 9 cowbird and 3 host eggs) may abandon nest. Nesting success reduced much less than that of smaller hosts; reduction in productivity due mostly to removal of host eggs by female cowbirds, rather than by young being overwhelmed by parasite fledgling(s).
Movements. Migratory. Core wintering range C Venezuela (especially Portuguesa and W Guárico); winters also, in highly erratic manner, from W Mexico (S Sinaloa) S to W Colombia, and in N South America from N Colombia E to Guianas and N Brazil. Forms post-breeding flocks, often in late Jul, these may move into areas of abundant food before undertaking long-distance movements; pre-migratory birds may accumulate up to 15 g of fat. Mostly nocturnal migrant. Migration route probably through Mexico and Central America, as species is rare in occurrence in Caribbean (rare migrant Bahamas, San Andrés I and Providencia I Sept–Nov and Mar, very rare Jamaica and Cuba, apparently absent Hispaniola, vagrant elsewhere in West Indies); arrival in wintering areas in Sept or Oct, in Trinidad in Dec or Jan or not at all (implying movements from other wintering areas on mainland). Wintering areas abandoned in late Mar and early Apr, huge flocks breaking up into smaller groups that then migrate together; peak passage of nocturnal migrants over S Texas in late Apr, arriving on territory in May, earlier in S than in N. Small numbers overwinter in breeding areas in some years. Vagrant to W Palearctic (one record S Norway, one Azores) and to Clipperton I (E Pacific, c. 1000 km SW of Mexico).
Status and Conservation. Not globally threatened. Locally common. Has fluctuated widely, both in total numbers and in geographical distribution, for much of its known history. Core breeding area centred on Midwestern States, from SE South Dakota and E Nebraska E to Illinois, S to N Texas, Oklahoma and Arkansas; outside this core, breeds N to Indiana and Michigan, and from North Dakota S to S Texas, Louisiana and N Alabama. Breeds or has bred, often very irregularly, in a large area peripheral to above, including S Canada (S Saskatchewan, Manitoba, Ontario), E to New York and Maryland, Virginia and Georgia, and W to E Montana, Wyoming and New Mexico. Previous distribution may have been, at least on occasion, still wider, including Atlantic Provinces of Canada and E seaboard of USA S to Florida and, in W, to California, Arizona and NW Mexico (Baja California). In wintering range, varies from being rare to being extraordinarily abundant in rice-growing areas in Costa Rica; in Trinidad, was unknown for extended period of time, abundant at other times. Populations have historically expanded owing to provision of abundant winter food resources in form of rice and sorghum. Major shrinkages in both numbers and range documented since c. 1960, with 30% decline in total numbers between 1966 and 1978, since when population has stabilized somewhat; remaining large grasslands may be insufficient for long-term population stability. Provision (and destruction) of suitable habitat by agriculture has had very significant effects on populations; may prefer modified habitats, such as hay fields, over "natural" prairie grasslands, but early mowing for hay can make these less productive in terms of young raised. On wintering grounds, huge flocks a major agricultural pest, provoking control efforts which may be significant cause of declines. Since wintering birds so highly concentrated (one Venezuelan flock, estimated at almost 3,000,000 individuals, probably comprised c. 30% of global population), control measures, such as aerial spraying with organophosphate pesticides, could have very major impact; one Venezuelan farmer said to have killed estimated over 1,000,000 individuals in this manner. More recently such occurrences have apparently decreased, most farmers relying on acoustic deterrents, but they do still happen.

Genus *PHEUCTICUS* Reichenbach, 1850

2. Yellow Grosbeak

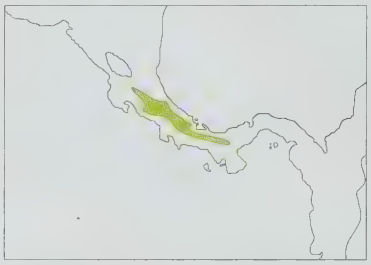
Pheucticus chrysopeplus

French: Cardinal jaune **German**: Gelbkopf-Kernknacker **Spanish**: Picogrueso Amarillo
Other common names: Mexican Yellow Grosbeak

Taxonomy. *Coccothraustes chrysopeplus* Vigors, 1832, San Blas, Nayarit, Mexico.
Has been treated as conspecific with *P. tibialis* and *P. chrysogaster*. Has hybridized with *P. melanocephalus* in captivity. Proposed race *rarissimus* (described from Chietla, in Puebla) subsumed in nominate. Three subspecies currently recognized.
Subspecies and Distribution.
P. c. dilutus van Rossem, 1934 – breeds NW Mexico (C Sonora, SW Chihuahua, N Sinaloa); wintering areas not known.
P. c. chrysopeplus (Vigors, 1832) – W Mexico (C Sinaloa and W Durango S on Pacific slope to N Guerrero and SW Puebla).
P. c. aurantiacus Salvin & Godman, 1891 – S Mexico (highlands of S Chiapas) and adjacent Guatemala.

Descriptive notes. 21·5–24 cm; one female 77·6 g. Male nominate race has crown and nape to centre of mantle deep yellow, side of mantle black (fresh feathers having narrow yellow edgings), back and rump bright yellow with some diffuse darker mottling, uppertail-coverts black with broad white tips; shoulder and upperwing black, broad white tips on greater and median secondary coverts and on tips of outer webs of secondaries and tertials; base of primaries white (conspicuous white flash on closed wing); rectrices black, three outermost with extensive white on inner webs; side of face and chest deep yellow, some black spotting on sides (variable, and often concealed), rest of underparts yellow, thigh dull black, undertail-coverts white; iris dark brown; upper mandible blackish, lower mandible pinkish-flesh to bluish-grey with dusky along distal half of cutting edge; legs bluish-grey. Female is much duller than male, crown and nape heavily streaked blackish, shoulder blackish-brown with dull yellowish edgings, white on wing as in male but generally somewhat reduced in extent; white on tail much reduced and tinged with brownish. Juvenile resembles female; immature male similar to adult

On following pages: 3. Black-thighed Grosbeak (*Pheucticus tibialis*); 4. Golden-bellied Grosbeak (*Pheucticus chrysogaster*); 5. Black-backed Grosbeak (*Pheucticus aureoventris*); 6. Rose-breasted Grosbeak (*Pheucticus ludovicianus*); 7. Black-headed Grosbeak (*Pheucticus melanocephalus*); 8. Northern Cardinal (*Cardinalis cardinalis*); 9. Vermilion Cardinal (*Cardinalis phoeniceus*); 10. Pyrrhuloxia (*Cardinalis sinuatus*).



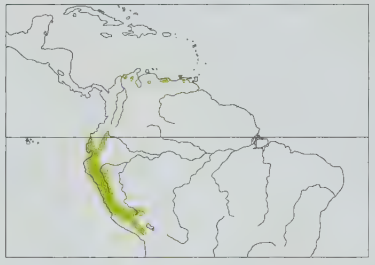
female, but head yellower, conspicuous white flash at base of primaries; takes two years to gain full plumage. Race *dilutus* is similar to nominate, but concealed bases of rump feathers black, mantle predominantly black with yellow flammulations, female much greyer and duller, more heavily streaked above, paler yellow below, flanks streaked dusky; *aurantiacus* is much more orange-yellow, bases of rump feathers black. Voice. Song a series of rich, clear whistles, "chee wee cheer weer weeuh" and so on, similar to that of *P. melanocephalus* but slower and more simple. Calls include sharp metallic "plihk" and a soft whistle, "hoee", given in flight.
Habitat. Tropical deciduous and semi-deciduous forest, well-wooded watercourses, scrubby woodland and thorn-forest; race *aurantiacus* also in clearings in humid evergreen forest. Sea-level to 2500 m in Mexico; 300–2500 m in Guatemala.
Food and Feeding. In Mexico, seen to take fruit of *Ficus pertusa*, *Trichostigma octandrum* (Phytolaccaceae) and, more rarely, *Recchia mexicana* (Surianaceae) in Jalisco, and to take nectar from *Erythrina oliviae* in Puebla. Forages singly and in pairs, often in fruiting trees; only rarely joins mixed flocks.
Breeding. Nesting begins in early Jun, and family parties still together mid-Sept, in N Mexico (Sonora). Nest a cup made from roots, leaves, grass and dry fibres, lined with finer rootlets, placed at low to medium height in thick bush. Eggs 2–5 bluish-green, flecked at blunt end with dark or clear grey-brown. No other information.
Movements. S populations sedentary. In N part of range (Sonora), race *dilutus* a summer visitor, arriving mid-May (rarely late Apr), departing mid-Sept; wintering grounds unknown. Rarely in winter in S Sonora. Vagrant in extreme S USA (S Arizona): about a dozen records in late spring or early summer.
Status and Conservation. Not globally threatened. Locally fairly common; S race *aurantiacus* described variously as rare and very local, and fairly common to common. May be captured for cagebird trade.
Bibliography. Armani (1983), Eguiarte & del Rio (1985), Fischer (1994), Howell & Webb (1995), Land (1970), Mees (1970), Meise (1938a), Pelikan (2004), Russell & Monson (1998), Schönwetter & Meise (1981), Stotz *et al.* (1996), Sibley (2003), Toledo & Hernández (1979), Vaes (2008).

3. Black-thighed Grosbeak

Pheucticus tibialis

French: Cardinal à cuisses noires **Spanish**: Picogrueso Muslinegro
German: Schwarzschenkel-Kernknacker

Taxonomy. *Pheucticus tibialis* Lawrence, 1867, Cervantes, Costa Rica.
Has been treated as conspecific with *P. chrysopeplus* and *P. chrysogaster*. Monotypic.
Distribution. Mountains from N Costa Rica (from Volcán Miravalles, in Guanacaste) S to W Panama (Bocas del Toro, Chiriquí and Veraguas).



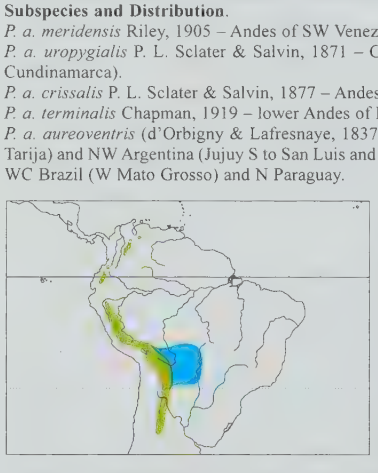
Descriptive notes. 20 cm; average 62·3 g (12 birds, Panama). Male has crown and nape to upper mantle bright yellow, lower mantle black with yellow edgings on central feathers, lower back and rump bright yellow, uppertail-coverts black with yellow tips, rectrices black; shoulder and upperwing black, primaries with broad white bases (conspicuous white flash); lores dull grey-black, ear-coverts and throat yellow with black mottling; chest deep yellow with diffuse darker mottling, rest of underparts yellow, thigh black; iris brown; upper mandible black, lower mandible grey; legs dull lead-grey. Female is less bright yellow than male, especially on head and neck; yellow edgings of back feathers more extensive and extending to scapulars, white flash on closed wing smaller. Juvenile is more olive, less yellow, on head, crown feathers often with fine central streaks, rump feathers streaky, breast with obscure mottling. Voice. Song a cheerful series of rich, varied leisurely musical whistles and phrases, interspersed with the phrase "tweek tseewee", sometimes ending in canary-like trill. Call a sharp "pik".
Habitat. Forest edges, clearings, pastures with residual trees. In Costa Rica from c. 1500 m to at least 2600 m, but down to 1000 m on Caribbean slope; mainly 750–1200 m in Panama, in W Chiriquí higher, mostly above 1800 m.
Food and Feeding. Diet includes seeds and fruits, also invertebrates. Usually forages fairly high up in forest, occasionally descending to middle levels. Gleans items from tips of branches; sometimes takes them in mid-air.
Breeding. Season Mar–May in Costa Rica. Nest a frail cup of rootlets, built on to bulky base of twigs or mosses, 3–9 m up in small tree or vine tangle. Clutch 2 eggs, pale blue with dots or blotches of dull chestnut-brown and purplish-lilac. No other information.
Movements. Resident. Some evidence of altitudinal migration on Caribbean slope of Costa Rica, numbers of migrants varying from year to year.
Status and Conservation. Not globally threatened. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Fairly common in Costa Rica; local or uncommon in Panama.
Bibliography. Carriker (1910), Garrigues & Dean (2007), Ridgely & Gwynne (1989), Schönwetter & Meise (1981), Stiles & Skutch (1989), Stotz *et al.* (1996).

4. Golden-bellied Grosbeak

Pheucticus chrysogaster

French: Cardinal à tête jaune **Spanish**: Picogrueso Ventriamarillo
German: Gelbbauch-Kernknacker
Other common names: Southern Yellow Grosbeak, Yellow-bellied Grosbeak

Taxonomy. *Pitylus chrysogaster* Lesson, 1832, Chile; error = Quito, Ecuador.
Has been treated as conspecific with *P. chrysopeplus* and *P. tibialis*. Two subspecies recognized.
Subspecies and Distribution.
P. c. laubmanni Hellmayr & Seilern, 1915 – N Colombia (Sierra Nevada de Santa Marta), Sierra de Perijá, and N Venezuela (discontinuously in Lara, Aragua, Distrito Federal and Miranda; also S Sucre and N Monagas).
P. c. chrysogaster (Lesson, 1832) – Andes from SW Colombia (Nariño) to S Peru (Arequipa and Puno); also coastal N & C Peru.
Descriptive notes. 21·5 cm; 54–59·7 g (Peru). Male nominate race has head and nape deep yellow with orange tinge, back black, rump yellow, uppertail-coverts black with white tips; upperwing



black, primaries with white bases (conspicuous white flash), secondaries with white tips on outer webs, tertials with much larger white tips, median and greater upperwing-coverts with broad white tips (prominent bars on closed wing); sometimes yellow shoulder patch; rectrices black, all except central two pairs with white on inner web and part of outer web; throat and underparts bright yellow, except for black thigh and white undertail-coverts; iris dark brown; upper mandible black, lower mandible bluish-grey; legs bluish-grey. Female has crown dull yellow, heavily streaked black, upperparts greenish-yellow, brightest on rump, with blackish streaks, shoulder dull grey-brown with greenish tinge; primary coverts and greater coverts dull blackish-grey, white tips to median and greater coverts; rectrices dull blackish-brown, small white tips on outermost feathers; chin to lower belly yellow, greenish-yellow on flanks, undertail-coverts dull white; bare parts as for male. Juvenile has crown, nape, ear-coverts, back and rump heavily marked with black streaks, white on tertials largely absent, white flash on primaries reduced, flanks with diffuse dark streaks. Race *laubmanni* is similar to nominate, but male has more extensive yellow fringes on interscapular feathers, scapulars narrowly edged dull olive-yellow on both webs, conspicuous white edgings on distal half of outer five primaries, female with same edgings on primaries, upperparts brighter yellow than nominate. Voice. Song a rich carolling, similar to that of Highland Hepatic-tanager (*Piranga lutea*) but sweeter, shorter phrases with more slurred notes. Call a sharp squeaky "pink".
Habitat. Open woodland, forest edge, areas of scattered trees, brushland; mostly fairly arid habitats, but in Peru also in more humid areas. In Ecuador, common in some human-dominated habitats. Mostly 1500–2500 m in Venezuela and Colombia; to 3500 m in Ecuador and Peru, though down almost to sea-level in arid SW Ecuador.
Food and Feeding. Few published data. Stomach contents "purplish berries" and "insects and seeds". Arthropod prey taken from foliage.
Breeding. Breeds during rainy season, Feb–May, in arid W Ecuador, and birds in breeding condition in Apr–Jul in N Colombia (Santa Marta and Perijá); probably single-brooded in Ecuador. Nest a loose, shallow twiggy cup, lined with fine rootlets and plant fibres, placed 2·8–4·3 m up in bush or smaller tree. Clutch 2–4 eggs, deep blue-green, blotched and marked with brown; incubation mostly by female, occasionally by male, period probably c. 14–16 days; nestling period c. 11 days, young leave nest when barely capable of flight. Nests frequently parasitized by Shiny Cowbird (*Molothrus bonariensis*).
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Fairly common to common in some areas of range.
Bibliography. Brook (1916), Carriker (1910), Clements & Shany (2001), Hilty (2003), Hilty & Brown (1986), Marchant (1960), Ridgely & Greenfield (2001a), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Sarmiento (2005, 2010), Schönwetter & Meise (1981), Schulenberg *et al.* (2007).

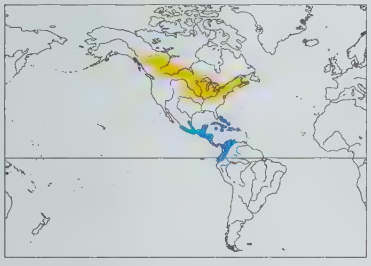
5. Black-backed Grosbeak

Pheucticus aureoventris

French: Cardinal à dos noir **German**: Goldbauch-Kernknacker **Spanish**: Picogrueso Dorsinegro
Other common names: Yellow-rumped Grosbeak (*uropygialis*); Riobamba/Yellow-throated Grosbeak (*crissalis*); Chapman's Grosbeak (*terminalis*)

Taxonomy. *Pitylus aureoventris* d'Orbigny and Lafresnaye, 1837, Yungas, Sicasica, Bolivia.
May hybridize with *P. chrysogaster* in Ecuador. Five subspecies recognized.
Subspecies and Distribution.
P. a. meridensis Riley, 1905 – Andes of SW Venezuela (Mérida).
P. a. uropygialis P. L. Sclater & Salvin, 1871 – Colombia in E Andes (Norte de Santander S to Cundinamarca).
P. a. crissalis P. L. Sclater & Salvin, 1877 – Andes of SW Colombia (Nariño) S to C Ecuador.
P. a. terminalis Chapman, 1919 – lower Andes of Peru (Amazonas and Cuzco).
P. a. aureoventris (d'Orbigny & Lafresnaye, 1837) – S Peru (Puno), S & E Bolivia (La Paz S to Tarija) and NW Argentina (Jujuy S to San Luis and Córdoba); also, probably only in austral winter, WC Brazil (W Mato Grosso) and N Paraguay.

Descriptive notes. 22 cm; 43·8–57·2 g (Bolivia), 55·4–66·2 g (Colombia). Male nominate race has upperparts black, sometimes with narrow yellow fringes on rump feathers and white tips to longest uppertail-coverts; shoulder patch yellow; upperwing black, primaries with broad white flash at base, median and greater coverts with broad white tips (conspicuous bars on closed wing); rectrices blackish, outermost feathers with large white areas on inner webs and some white on outer webs; chin to upper breast black, lower breast and rest of abdomen bright yellow, sometimes with some orange on line down mid-belly, sides and flanks variably flecked black, undertail-coverts much whiter, with small black tips; underwing pale yellow; iris brown; upper mandible black, lower mandible blue-grey; legs blue-grey. Female is similar to male, but browner and more mottled with yellow above, mostly yellow with dusky speckling below, except on belly; less white on rectrices. Immature male has crown dull blackish-brown with yellowish mottling, throat dull yellow, diffusely mottled blackish, flight-feathers dull brownish-black, reduced white markings in wing and tail. Race *meridensis* has upperparts including uppertail-coverts black, back with some concealed yellow feathers, rump golden with a few black spots, belly yellow and always unspotted; *uropygialis* is similar to previous, but less yellow on rump, has black spots on side of abdomen, no concealed yellow feathers on back, female has more black on throat than other races; *crissalis* differs very obviously from other races in having yellow, not black, throat and chest and buffy-white undertail-coverts; *terminalis* is closest to *meridensis*, but few or no black markings on sides and flanks, white tips of greater wing-coverts larger, interscapulars spotted yellow, has large white terminal (or subterminal) rounded spots (instead of small whitish transverse subterminal marks) on uppertail-coverts, thigh yellow. Voice. Song a rich, melodious series of whistled notes, similar to that of *P. chrysogaster* but thinner; call a sharp "keck".



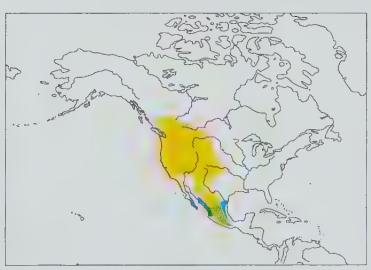
Habitat. Mostly dry to arid scrubby, often open, woodland, well-bushed gardens and similar; generally in more arid locations than those favoured by *P. chrysogaster*, but the two may occur in same habitat locally. In La Rioja, in Argentina, found in humid scrub ravines, forest and Chaco. Mostly 1450–2000 m, occasionally to 3700 m, in Venezuela, 1700–3000 m in Colombia, and mostly 1200–3200 m in Peru; down to 600 m at S end of range.
Food and Feeding. Diet includes berries, seeds, and insects. At Chía, in Colombia, seen to feed extensively on flowers and seeds of *Polymnia pyramidalis* in Apr during flowering period; insects less than 5% of stomach contents of specimens from same location. Usually solitary or in pairs, but several individuals may gather at favoured fruiting trees; does not join mixed-species flocks. Forages mostly high up, but also at all levels of forest, even on ground.
Breeding. Little published information. Birds with enlarged gonads at end of Jan (Cauca) and juvenile in Nov (Nariño) in Colombia; nest with eggs, nest with young and one other pair feeding fledged chick on 18th Dec in Argentina, where nesting continues into Jan. Following details refer to nominate race in Argentina. Nest a cup made from stalks of vines, lined with rootlets and fine fibres, external diameter 10–12 cm, cup diameter 5–7 cm, cup depth 5·5–6 cm, two nests 2·7 m and 3 m above ground in shrub. Clutch 2–3 eggs, greenish or clear blue, with fine brown spots concentrated at blunt end; no information on incubation and fledging periods. Nests frequently preyed on by Plush-crested Jay (*Cyanocorax chrysops*).
Movements. Most populations apparently sedentary; some evidence of movement at geographical ends of range, and possibly some altitudinal movement in NW Argentina and adjacent areas. Occurs in Mato Grosso (Brazil) and N Paraguay, but apparently does not breed; possibly some movements in Venezuela.
Status and Conservation. Not globally threatened. Uncommon or rare in Venezuela; locally common, though in small numbers in Colombia; rare to locally common in Peru. Recently recorded from mouth of R Lluta, in N Chile (Arica), but status there not known. Sometimes trapped for cagebird trade. May cause damage to fruiting crops.
Bibliography. Armani (1983), Clements & Shany (2001), Contreras (1979b), Dinelli (1924), Echeverry-Galvis & Morales-Rozo (2007), Echeverry-Galvis *et al.* (2005), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Johow (2000), Narosky & Yzurieta (2003), Nores & Cerana (1990), de la Peña (2005), Ridgely & Greenfield (2001a), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Salinas (2000), Schulenberg *et al.* (2007), Short (1975), Sick (1993, 1997).

6. Rose-breasted Grosbeak

Pheucticus ludovicianus

French: Cardinal à poitrine rose **Spanish**: Picogrueso Pechirrosado
German: Rosenbrust-Kernknacker
Other common names: Common Grosbeak

Taxonomy. *Loxia ludoviciana* Linnaeus, 1766, Louisiana, USA.
In the past, this species and *P. melanocephalus* sometimes placed in a separate genus, *Hedymeles*; the two have been thought to form a superspecies, and frequently considered conspecific; they hybridize in overlap zone E of Rocky Mts. Monotypic.
Distribution. Breeds S Canada from extreme S District of MacKenzie E to Great Slave L and NE British Columbia, and C & N Alberta, E to Ontario (S from N shore of L Superior), S Quebec (S of c. 49°) and SE Newfoundland, S in USA to NE North Dakota, E South Dakota, NE Nebraska, NC Ohio, Pennsylvania and New Jersey, and inland at higher altitudes to extreme N Georgia. Migrates to region from NE & W Mexico (from SW Tamaulipas and Nayarit) S through Central America to Colombia, Ecuador, Peru, rarely E to Guyana; also West Indies (mostly Bahamas, Cuba, Cayman Is) and sparingly Bermuda.



Descriptive notes. 18–20 cm; male 36–63 g, female 34–56 g. Male has head down to upper chest, back and shoulder black, lower back and rump white, uppertail-coverts black with broad white tips; upperwing black, median coverts largely white, greater coverts with large white tips on outer webs, primaries with broad white bases (prominent white patch on closed wing); rectrices black, outer feathers with broad area of inner webs white; chest and centre of lower chest rose-red, upper and lower flanks, belly and vent white with variable amount of black streaking at sides, especially lower down; thigh black; underwing-coverts rose-pink; iris dark brown; bill pinkish-white to slate-grey, darker on tip of culmen; legs greyish-blue to slate-brown. Female has crown medium-brown, with broad central stripe buff-brown, streaked with medium-brown, broad whitish supercilium extending past ear-coverts, which are dark brown, pale off-white crescent under eye; upperparts medium-brown with paler buff-brown and darker brown streaks; primaries grey-brown, narrowly edged paler on outer webs, wing pattern as in male but with white areas reduced in extent and more buffy; rectrices uniformly dull medium-brown; throat whitish-yellow or yellowish-brown, becoming more strongly coloured on chest and belly, with narrow blackish-brown streaks on centre of chest and extending to flanks, where become more diffuse; lower belly and vent brownish-yellow; bill less whitish than male's. Juvenile resembles female, but has cinnamon wingbars and tawny edgings of feathers of upperparts, underwing-coverts pink (male) or orange-yellow (female); second-year male like adult, but with variable amount of brown edgings on black of upperparts, especially head, and primaries duller blackish-brown. Voice. Song, usually from elevated perch, occasionally in flight, a very attractive series of loud warbling notes in rapidly repeated phrases with short gaps in between, continued for 6 seconds or more, in periods of high excitement almost continuous; sometimes likened to song of American Robin (*Turdus migratorius*), but without distinct pauses between phrases. Female also sings (when nest-building, relieving male at nest, incubating or brooding). Some individuals incorporate into song elements of songs of other species, e.g. Red-eyed Vireo (*Vireo olivaceus*), *Cardinalis cardinalis* and Eastern Towhee (*Pipilo erythrophthalmus*). Calls include metallic "chink" and harsh "squawk".
Habitat. Breeds in woodland of various types, including exclusively deciduous stands of maple (*Acer*), cherry (*Prunus*) and the like, mixed deciduous/coniferous woods, second-growth woodland, stream edges, also well-wooded suburban areas; usually partially open, rather than full closed-canopy woodland. Colonizes logged areas c. 15 years after cutting. On migration, also in scrub and woodland, thickets etc., including urban areas. On wintering grounds, various types of semi-open forest, second-growth woodland, pasture with scattered trees, and even urban parks with ornamental trees. Sea-level to 2000 m, usually above 900 m and occasionally to 3800 m.
Food and Feeding. Mixed diet, composition varying during course of year. On summering grounds, about equally split between animal and vegetable material, but during nesting period proportion of animal food rises to almost three-quarters; mostly arthropods, including beetles (Coleoptera), bugs (Hemiptera), caterpillars, bees (Apoidea), ants (Formicidae) and similar; vegetable matter includes fruits of elderberry (*Sambucus*), *Rubus* species, mulberry (*Morus*), also weed seeds such as pigweed and milkweed (*Asclepias*). Nestling diet c. 75% animal matter. On migration almost entirely frugivorous (analysis of faecal samples). Fewer data from wintering grounds, but eats oil-rich arillate seeds and fruits and some animal matter. Frequently visits bird feeders. Animal items gleaned from foliage, mostly in canopy, males gleaning more from twigs and females more from leaves; later in season forages lower down to take advantage of fruit crop, and sometimes on ground. In winter forages high in trees. Feeds also acrobatically, hanging upside-down from ends of twigs; also pursues flying insects on the wing.
Breeding. Season Apr–Aug/Sept, later in N of range; single-brooded, occasionally two broods. Males arrive on breeding grounds several days before females. Male occasionally performs song flight at elevation of 5 m or more. Nest-site may be selected by both sexes; nest built mostly by female, with some help from male, a loose, apparently flimsy, open cup made from small twigs, weed stems, bark strips, straw and similar, external dimensions 10 × 20 cm, cup 7 × 15 cm, placed 0·8–17 m (average c. 6 m) above ground and usually in vertical crotch of sapling or small tree; exceptionally, nest reused in subsequent years. Clutch 3–5 eggs, mostly 4, occasionally 1–2, pale blue, green or green-blue, marked, especially at blunt end, with reddish-brown or purplish-red blotches and speckles; incubation by both sexes, about two-thirds by female during daytime, exclusively by female during night, incubation period 12–13 days; chicks brooded by both sexes, also fed by both sexes, but more by female, nestling period 9–12 days, usually 10 days; fledglings attended for a further three weeks; when female involved in second brood, young tended by male alone. Nests parasitized by Brown-headed Cowbird (*Molothrus ater*), parasitism rates generally low, below 10% in most of range, higher in Great Plains (23% in one study); usually succeeds in raising young despite presence of cowbird chicks.
Movements. Entirely migratory; winters in Middle America and NE South America, a few in S USA (S Texas E to Florida, casually farther N). Leaves breeding grounds by mid-Aug in W Canada (Alberta), by late Sept in NE USA and E Canada, with median migration dates on Gulf Coast mid-Oct; passage in Bermuda mostly in Oct, with some as late as late Nov. Ringing results show that birds in N part of wintering range (Guatemala, Honduras and El Salvador) originate predominantly, but not exclusively, from breeding areas W of 80° W, while the rather fewer recoveries in Panama, Venezuela and Colombia originate from New England (NE USA) and areas around L Erie and L Ontario; no recoveries in winter of individuals ringed in W Canada (NE British Columbia and Alberta E to Manitoba). Return in S USA in mid-Mar to mid-Apr and in S Canada (Ontario) mid-Apr to early May, somewhat later in N & NW parts of range. Numerous extralimital records; after Red-eyed Vireo (*Vireo olivaceus*) and Blackpoll Warbler (*Dendroica striata*) probably the most frequent transatlantic passerine vagrant, with numerous records from Iceland, Britain (at least 22 records up to 2009), Ireland, Norway, Sweden, France, Spain, Malta, former Yugoslavia and Azores, majority involving immatures in autumn, especially in Oct. Recorded also in SW USA (California) and Galapagos Is.
Status and Conservation. Not globally threatened. Common in much of breeding range; more sparsely distributed in NE (Newfoundland). Generally exhibits considerable tolerance of human modification of habitat, although in American Midwest has been identified as a species of management concern. Differing data as to effect of forest fragmentation; one study, in SW Ontario, indicated that productivity little affected by forest-patch size, while a second, in SC Ontario, showed significantly lower productivity in small woodland fragments. One of main causes of poor nesting success in fragmented forest said to be increased cowbird parasitism, which would appear to be less damaging to this species than to smaller ones such as warblers (Parulidae) and vireos (Vireonidae). Effect of trapping for cagebird trade (widespread in Central America) unlikely to be great. More work needed to assess likely results of habitat change on wintering grounds.

7. Black-headed Grosbeak

Pheucticus melanocephalus

French: Cardinal à tête noire **Spanish**: Picogrueso Cabecinegro
German: Schwarzkopf-Kernknacker

Taxonomy. *Guiraca melanocephalus* Swainson, 1827, Tableland, Temascaltepec, Mexico.
In the past, this species and *P. ludovicianus* sometimes placed in a separate genus, *Hedymeles*; the two have been thought to form a superspecies, and frequently considered conspecific; they hybridize in overlap zone E of Rocky Mts. Proposed race *rostratus* (Nuevo León, in NE Mexico) included within nominate. Two subspecies recognized.
Subspecies and Distribution.
P. m. maculatus (Audubon, 1837) – breeds along Pacific coast from SW Canada (SW British Columbia S from c. 53° N, also S Vancouver I) S in W USA to California and to extreme NW Mexico (to c. 30° N in Baja California); winters S Baja California and mainland Mexico.
P. m. melanocephalus (Swainson, 1827) – breeds from SW Canada (SE British Columbia, S Alberta and SW Saskatchewan) and WC USA (NW North Dakota, S through Rocky Mts and W Great Plains) S through Mexican highlands to Oaxaca; winters within Mexican breeding range.

Descriptive notes. 18–20·5 cm; 35–49 g. Male nominate race has head, chin and ear-coverts black, narrow orange-brown band on hindneck sometimes extending onto head as postocular streak; mantle and upper back black with some orange-brown to whitish fringes, lower back and rump orange-brown; upperwing blackish, broad white edgings on median coverts, narrower white edges on greater coverts, primaries with broad white bases (large white flash on wing in flight), outermost primaries narrowly edged whitish on outer web, tertials blackish with some white on outer webs; rectrices black, outer feathers with broad area

of white on inner webs; throat, chest and most of underparts orange-brown, bright yellow centre of upper belly, white centre of lower belly, white undertail-coverts diffusely tinged orange-brown near vent; underwing-coverts bright yellow; iris brown; upper mandible slate-brown or medium-brown, lower mandible bluish-white or creamy, tip brown; legs slate-grey. Female has crown dark brown with inconspicuous narrow medium-brown scaling, broad buffy central band, latter streaked darker brown, long pale supercilium from bill base to side of hindneck; upperparts with buff-brown and darker brown streaks, upperwing dull brown, wing pattern as in male but with white areas reduced in extent (especially at base of primaries) and more buffy, rectrices uniformly dull medium-brown; chin buffy white, throat and underparts brownish-yellow, variable amounts of yellow on centre of lower chest and upper belly, sides and flanks with variable blackish streaking; underwing-coverts bright yellow. Juvenile resembles female, but has cinnamon edgings on upperwing-coverts, feathers of upperparts edged with tawny; second-year male varies in plumage, often like adult, but distinguishable by brown mottling on blackish areas, some retaining a more immature aspect than others. Race *maculatus* is very like nominate, but smaller, with more prominent orange-brown postocular stripe. VOICE. Male song, from perch and in flight, a pleasant series of ascending and descending warbled syllables separated by brief pauses; similar to that of *P. ludovicianus* but faster and higher, with more discrete pauses between phrases. Female song generally, though not invariably, distinguishable from male's by having both syllables and pauses on average shorter; female songs which are indistinguishable from those of male may be used "deliberately" in deceptive manner, as when female requires immediate return of male (e.g. when nest threatened). Calls include sharp "pik", similar to corresponding call of *P. ludovicianus* but less sharp, also a squealing distress or agonistic call.

Habitat. Various types of generally semi-open woodland, including coniferous, deciduous and mixed forest, e.g. oak (*Quercus*), juniper (*Juniperus*), pinyon pine (*Pinus*), willow (*Salix*), cottonwood (*Populus*). Also well-wooded modified habitats such as orchards, suburbs with trees. In Mexico, arid to semi-humid oak, pine–oak and deciduous woodland. Winter habitat more varied, including humid evergreen forest. From sea-level to highlands; in Mexico sea-level to 2500 m in Baja California, 1500–3000 m in mainland.

Food and Feeding. Diet animal and vegetable matter; stomach contents during breeding 66% animal, 34% vegetable. Recorded items include beetles (Coleoptera), bugs (Hemiptera), spiders (Araneae), once a small fish; seeds of various plants, including dock (*Rumex*), oats (*Avena*), pigweed, cranesbill (*Geranium*) etc., also fruits of strawberry (*Fragaria*), poison oak (*Toxicodendron*), cherries (*Prunus*), blackberries (*Rubus*) and others. Those with wintering range in Mexico overlapping that of monarch butterfly (*Danaus plexippus*) feed heavily on torpid adults of this butterfly, which are protected from many predators by toxic cardenolides derived from their foodplant, the milkweed (*Asclepias*); present species apparently selective, targeting male butterflies (which seem to have lower level of toxins than females) in order to avoid or minimize effects of toxins; also, does not eat butterflies continuously but, instead, feeds for periods of about eight days and then moves on to other prey, perhaps to allow ingested toxins to dissipate; in contrast to other bird species, appears immune to emetic effects of cardenolides, although after prolonged ingestion does show signs of malaise. Often feeds with Black-backed Orioles (*Icterus abeillei*) at monarch sites. Otherwise, forages at all levels, mostly by gleaning from foliage and twigs.

Breeding. Egg-laying begins late Apr to late Jun in USA, earlier dates referring to S parts of range and lower altitudes; no data on resident Mexican population. Monogamous. Forms pair-bond rapidly on arrival on territory, often on day of female's appearance. Nest built almost entirely by female, very rarely some assistance from male, a loose, rather untidy open cup made from slender twigs, plant stems, rootlets and similar, lined with finer plant material and hair, sometimes also with green material, located 1–8 m (average 3–4 m) above ground in outer branches of small deciduous tree, or in pinyon or juniper. Clutch 2–5 eggs, usually 3–4, pale blue or greenish-blue, heavily blotched and spotted with reddish-brown or medium-brown; incubation by both sexes during day, by female alone at night, period 12–14 days; small chicks brooded by both parents by day, by female at night, fed by both parents, for first few days fed with mashed prey, later with whole items (e.g. caterpillars), nestling period 10–14 days, shorter if nest disturbed; female may sing after young have left nest, song serving as means of calling fledglings to her. Nests parasitized by Brown-headed Cowbird (*Molothrus ater*) only rarely. A few males breed in second year, these tending to be of brighter, more adult-like plumage type.

Movements. Migratory in most of range; resident in highlands of C Mexico, from Zacatecas S to Oaxaca, where population augmented in winter by N migrants. Winter visitor in S Baja California and both W & E Mexico (S from S Sonora and Tamaulipas). In autumn, adult males depart first, from late Jul to Aug, followed by females and young; in Arizona (S USA), some move to lower altitudes before departing fully. Migrants return on territory from late Mar in N Mexico to second week of May in Canada (British Columbia); subadult males arrive significantly later than full adults. Probably a nocturnal migrant, but data lacking; some diurnal migration observed across Mojave Desert, in SW USA. Numerous vagrancy records throughout E North America, from SE Canada (Ontario E to New Brunswick) and New York E to Maine and New Hampshire, S to Virginia and Georgia; also Cuba, Curaçao and Costa Rica.

Status and Conservation. Not globally threatened. Common or abundant over much of breeding range in North America; common to fairly common in Mexico. In N part of range may benefit from partial clearing of densely wooded areas, e.g. ski-runs and hydro rights of way. Effect of habitat changes on Mexican populations unknown, although the species obviously can tolerate a significant amount of clearance. Predation on monarch butterflies significant during 135-day overwintering period of the insects: in one 2·25-ha study area, this species and Black-backed Oriole took an estimated 15,000 butterflies daily (based on discarded wings), with aggregate of more than 2,000,000, representing c. 9% of the monarch colony.

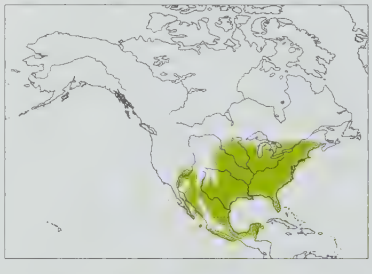
Genus *CARDINALIS* Bonaparte, 1838

8. Northern Cardinal

Cardinalis cardinalis

French: Cardinal rouge **German**: Rotkardinal **Spanish**: Cardenal Norteño

Other common names: (Common) Cardinal, Redbird; Long-crested Cardinal (*carneus*)



Taxonomy. *Loxia cardinalis* Linnaeus, 1758, South Carolina, USA.

Has in the past been placed in a separate genus, *Richmondena*. Forms a superspecies with *C. phoeniceus*; relationship of these two to *C. sinuatus* the subject of varying opinions. One documented example of a wild-bred hybrid between present species and *C. sinuatus*, and hybridization in captivity reported. In captivity has hybridized also with Red-crested Cardinal (*Paroaria coronata*) and Yellow Cardinal (*Gubernatrix cristata*), to neither of which species is it closely related, both being currently placed in family Emberizidae. Races fall into four groups based largely on colour of face mask of females, namely "*cardinalis* group" (comprising nominate, *floridanus*, *magnirostris* and *canicaudus*), "*coccineus* group" (*coccineus*, *littoralis*, *yucatanicus*, *phillipsi*, *flammiger* and *saturatus*), "*igneus* group" (*igneus*, *superbus*, *townsendi*, *affinis*, *sinaloensis*, *mariae*, *seftoni* and *clintoni*) and single-species "*carneus* group". In E Mexico, race *coccineus* intergrades with *canicaudus* in N coastal Veracruz and *yucatanicus* intergrades with *phillipsi* in S Yucatán Peninsula. Race *carneus* sometimes treated as a full species; conversely, *sinaloensis* treated by many authors as synonym of *affinis*, and *floridanus* sometimes subsumed into nominate. S USA populations in C Oklahoma, S Arkansas, SC Texas, all of Louisiana and SW Mississippi included in *magnirostris*, but some may belong with another race or represent as yet undescribed race(s). Nineteen subspecies currently recognized.

Subspecies and Distribution.

C. c. superbus Ridgway, 1885 – SW USA (extreme SE California E through Arizona to SW New Mexico) S to NW Mexico (N Sonora).
C. c. townsendi (van Rossem, 1932) – Tiburón I and adjacent coastal Sonora, in W Mexico.
C. c. affinis Nelson, 1899 – WC Mexico (SE Sonora, SW Chihuahua, Sinaloa and W Durango).
C. c. sinaloensis Nelson, 1899 – W Mexico (C & S Sinaloa S to Michoacán).
C. c. mariae Nelson, 1898 – Tres Marías Is (María Madre, María Magdalena and María Cleofas), off Nayarit, in W Mexico.
C. c. seftoni (Huey, 1940) – C Baja California (between c. 28° N and 27° N), in NW Mexico.
C. c. igneus S. F. Baird, 1860 – Baja California S of c. 27° N.
C. c. clintoni (Banks, 1963) – Cerralvo I, off SE Baja California.
C. c. carneus (Lesson, 1842) – W coast of Mexico from Colima S to Isthmus of Tehuantepec.
C. c. cardinalis (Linnaeus, 1758) – most of E half of USA and SE Canada from SE South Dakota S to E Oklahoma and C Louisiana, E to Atlantic coast (except SE Georgia and peninsular Florida).
C. c. floridanus Ridgway, 1896 – SE Georgia and peninsular Florida (SE USA).
C. c. magnirostris Bangs, 1903 – S USA from S Texas and C Oklahoma E to S Arkansas, Louisiana and SW Mississippi.
C. c. canicaudus Chapman, 1891 – W Oklahoma and C & W Texas S to C & E Mexico (from Coahuila S to E Jalisco, Guanajuato, C San Luis Potosí and Hidalgo).
C. c. coccineus Ridgway, 1873 – Atlantic slope of E Mexico in E San Luis Potosí, Veracruz, (except extreme S), NE Puebla and N Oaxaca.
C. c. littoralis Nelson, 1897 – lowlands of S Veracruz and Tabasco (SE Mexico).
C. c. yucatanicus Ridgway, 1887 – base of Yucatán Peninsula, in SE Mexico.
C. c. phillipsi Parkes, 1997 – coastal scrub of Yucatán.
C. c. flammiger J. L. Peters, 1913 – SE Mexico (C & S Quintana Roo), NE Belize and N Guatemala (Petén).
C. c. saturatus Ridgway, 1885 – Cozumel I (off NE Quintana Roo).

Introduced to Bermuda (probably nominate) and Hawaii (*canicaudus*); also Los Angeles, on coast of S California (probably *superbus* or *canicaudus*).

Descriptive notes. Male 22–23·5 cm, 37–52 g; female 21–21·6 cm, 36–51·5 g (nominate). Male nominate race has crown, elongated crest feathers, side of face and entire underparts bright red; nape, back and rump darker red, feathers lightly tipped with greyish; lores, lower forehead, area around bill and most of throat black; flight-feathers pinkish-grey on inner webs, outer webs reddish (giving overall red appearance to closed wing), with darker, duller red wing-coverts and alula; rectrices duller, darker red; iris deep brown; bill orange-red; legs medium-brown. Female is medium-brown above, underparts more buffy brown, elongated crest feathers strongly tinted with pinkish-red, some pinkish feathers in face; mask similar in extent to that of male, but dull greyish-black; primaries and outer secondaries dull brownish on inner webs, pinkish on outer webs (pinkish-brown appearance of closed wing), inner secondaries, tertials and wing-coverts brownish with pinkish feather centres, lesser and median coverts only narrowly edged brownish; underwing-coverts bright pink; rectrices brownish-grey with pinkish centres, duskier on inner webs; bare parts much as for male. Juvenile is similar to female, but overall much duller, with little or no red on crest, bill blackish or dusky grey, iris greyish; juvenile male can have some red on chest or flanks. Race *floridanus* is smaller and darker than nominate; *magnirostris* is much like previous, but bill larger and heavier, face mask more extensive, wing longer and tail shorter, red of male lighter (but more intense than nominate), female more whitish on central belly than nominate; *canicaudus* male is more intense red than nominate, with shorter wing and larger bill, black band above bill narrower, female greyer above and paler below than nominate and with less distinct mask; *coccineus* male is more intensely coloured than nominate, with larger bill and no greyish or brownish edgings on back feathers, female browner than nominate; *littoralis* is closest to previous, but male plumage more purple; *yucatanicus* is similar to *coccineus*, but smaller, and male lighter red; *phillipsi* is similar to last, but male paler red below, greyer on back, remiges paler and more orange-red, little or no red wash on tertials, female paler below, crest more orange-red, cheek greenish-buff; *flammiger* male is brighter than *yucatanicus*, purplish tinge on back, female heavily and more extensively washed with red below; *saturatus* is smaller than nominate, males almost inseparable from male *yucatanicus*, but feet larger, female less red on breast than either *yucatanicus* or previous; *superbus* is largest race, with bill stouter than nominate, black of face mask does not extend fully above bill, female duller above, with no black on face, throat whitish; *affinis* male is indistinguishable from last, female darker than last; *townsendi* is closest to previous, but male lighter red, paler and greyer on back, female paler, duller and more greyish-tinged; *igneus* is like *superbus*, but smaller, with shorter and thicker bill; *sinaloensis* is similar to *igneus* but smaller, with narrower and longer bill, male more pure and intense red, female darker; *mariae* is similar in size to *igneus*, but wing longer, tail shorter, feet larger and bill more bulging; *seftoni* is intermediate in size between *superbus* and *igneus*, with smaller bill than either; *clintoni* is similar in size to *igneus*, wing on average shorter, bill equal or longer, male with paler and less intense red underparts, female greyer dorsally; *carneus* is most distinctive race, bill with less sinuated tomia, crest feathers longer and stiffer and more distinctly outlined, face mask of female black. VOICE.

Vocalizations intensively studied. Both sexes sing, with broadly similar song types. Song typically a series of loud, cheerful monosyllabic whistles, "wheet- wheet-wit-wit-wit-wit" and so on, a dozen or so notes at a time, or disyllabic whistles, "wheata-wheata-wheata" etc.; or more complex whistles with up to four components. Considerable geographical variation in song (in North America; little work done in Mexico and Central America); e.g. songs in S Ontario, Texas and S Wisconsin frequently have two syllables, while in S Minnesota three syllables fairly common; nevertheless, some syllable and song types occur throughout North America. Male sings for much of year, female somewhat less. Song heard during much of day, and among males more tendency to switch song types during dawn chorus than later in day. Female often sings when incubating, which may result in visit to nest by food-carrying male (varies with female's song type). Usual contact call a liquid "chip", but at least 16 different calls recorded, including, among others, agonistic calls ("chuck, pee-too"), aggressive calls at feeder stations, pre-copulatory call of female ("see"), food-begging calls of nestlings.

Habitat. Semi-open areas with bushes, shrubs and small trees, forest edge, abandoned farmland with bushy growth, shrubby areas recovering from logging, and suburban gardens; race *phillipsi* confined to coastal scrub. Requires dense bushes for nesting and conspicuous songposts. In Ontario, where species reaches N limit of range, significantly higher densities in areas with extensive suburbs (e.g. in Ottawa region). In Mexico, from sea-level up to 2000 m (in Baja California); in USA, mostly below 1100 m, occasionally breeds up to 1500 m, in Colorado exceptional records up to 2597 m; introduced birds in Hawaii sparsely up to 2300 m, with a couple of occurrences on summit of Mauna Kea (4055 m).

Food and Feeding. Mostly vegetable matter (c. 70% over year), but young fed almost exclusively (95%) with animal matter. One analysis of stomach contents from 20 US states and Ontario showed seeds as major component (36% by weight), followed by wild fruit (24%) and other vegetable matter; invertebrate prey includes beetles (Coleoptera), grasshoppers (Orthoptera), butterflies and moths (Lepidoptera), homopteran bugs, hymenopterans and flies (Diptera); occasional slugs and snails (Gastropoda). In Florida, seen to eat nectar-containing parts of blossoms, especially in winter; in Hawaii, where introduced, has been seen to catch winged termites (Isoptera) in air. Observed to visit freshly excavated pits of sapsuckers (*Sphyrapicus*) in maple tree (*Acer*) bark, presumably for sweet sap; on one occasion, a male observed feeding on corpse of a dead field-mouse (Cricetidae), though was not seen to have killed it. In many parts of its range, a substantial proportion of its diet comes from artificial feeding stations, doubtless explaining the high population densities in suburbs. Forages singly and in pairs; also small loose flocks in non-breeding season.

Breeding. Virtually all studies have been conducted on North American populations. Start of nest-building varies according to location, from Feb in S to Apr in N; in Iowa, can begin while ground still snow-covered; in Belize, one nest with eggs on 17th Jun (race *flammiger*); up to 4 broods annually, and nesting as late as Oct recorded in West Virginia. Usually monogamous, some instances of bigamy by male recorded. Some birds remain paired throughout year; in other cases associate in small loose flocks in winter, males then returning to territory before females; or pair-members may quit flock together. Females do not show any significant preference for males with redder plumage over paler ones; apparently, other factors such as desirability of territory more important. Extra-pair fertilizations, as determined by DNA studies, seem to be less common than in some other passerines; in one study, 13·5% of young had genetic material from sources other than nesting pair. One instance of a juvenile assisting adults in feeding young, but not known if juvenile blood-related. Nest-site selected by both sexes; construction almost entirely by female, male occasionally bringing in material, work takes 3–9 days; an open bowl, with layers of rough outer material, leafy mat, grapevine bark and grassy lining, external diameter c. 11 cm, diameter of cup c. 7 cm, depth c. 3·6 cm, placed 0·25–12 m (most commonly 1–2 m) above ground, usually concealed by foliage or tangles, usually in deciduous bush such as multiflora rose (*Rosa multiflora*), honeysuckle (*Lonicera*), hawthorn (*Crataegus*) or similar, less commonly in conifer. Clutch 1–5 eggs, average 2–3, ground colour varies from greyish-white to buffy white or greenish-white, with spots or speckles of pale grey, medium-brown or rarely reddish-brown all over, but heaviest at blunt end (last egg always more lightly marked); incubation by female alone, starting with third egg, often fed on or away from nest by male, period c. 11–13 days; for first two days chicks brooded extensively by female, she may be fed by male at this time, young fed by both parents, nestling period 9–11 days; young can fly well at 19 days, become independent at 38–45 days. Some instances of two females sharing a nest, both feeding young. Common host of Brown-headed Cowbird (*Molothrus ater*) in most of range and Bronzed Cowbird (*Molothrus aeneus*) in SW USA, Mexico and farther S; in some areas parasitism rates very high, but presence of young cowbirds in nest seemed to have little effect on host's young, with no significant differences in weights and sizes (as measured by tarsus length) between nestlings in parasitized nests and those in unparasitized ones.

Movements. Generally sedentary. Occasional long-distance movements of irregular nature. Of 11,340 recoveries of individuals ringed in Canada and USA up to Aug 2010, 11,273 (more than 99%) showed zero or trivial movement; 66 moved more than 100 km from point of ringing, and of these almost half (30) moved less than 200 km, a further 27 moved 200–500 km, five between 500 km and 1000 km, and only four more than 1000 km. The most distant recoveries involved movements from Illinois SE to North Carolina, New Jersey E to Kansas, Arkansas N to Ontario and South Carolina N to Quebec. As revealed by one study covering ringing data up to 1962, those recovered at significant distances from ringing site were largely first-years; no difference in mobility between sexes. Directions of dispersal relatively random, with no predominant heading. Occurrences of individuals at locations well removed from recorded breeding range also indicate mobility; for example, one on shores of James Bay (Ontario) was 750 km N of current breeding range, while one in NE Newfoundland was more than 1200 km outside range, including not fewer than 110 km of open ocean. In Hawaiian group, race *canicaudus*, introduced on Kauai, Oahu and Hawaii, has subsequently colonized many other islands, apparently without further human intervention; three records on Nihoa, which would involve over-water movement of 275 km from nearest population.

Status and Conservation. Not globally threatened. Abundant over much of range in E & C North America; listed as Species of Special Concern in SE California. Population densities in ideal habitat can be very high; in S Texas in winter, estimated at 167 birds/km². Has expanded range dramatically over last 100 years, moving from Pennsylvania and New Jersey into New England. First nest recorded in Canada in 1901, and now an abundant breeding species in S Ontario N to Ottawa Valley; range in Ontario has expanded further during 1980–2005. Fewer data at S end of range; recently (1998) colonized Swan Is, 200 km N of Honduras, although this may have involved artificial introduction.

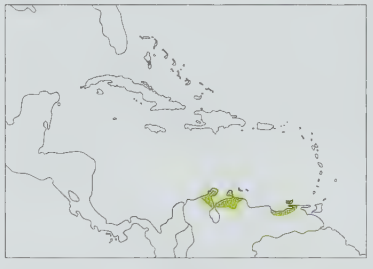
9. Vermilion Cardinal



Cardinalis phoeniceus

French: Cardinal vermillon **German**: Purpurkardinal **Spanish**: Cardenal de La Guajira
Other common names: Venezuelan (Scarlet) Cardinal

Taxonomy. *Cardinalis phoeniceus* Bonaparte, 1838, "the country south of the Bay of Honduras"; error = north Venezuela.

Has in the past been placed in separate genus, variously *Richmondena* and *Pyrrhuloxia*. Forms a superspecies with *C. cardinalis*; relationship of these two to *C. sinuatus* the subject of varying opinions. Race *robinsoni* was proposed for birds of Margarita I, but all claimed differences fall within range of variation of mainland birds, except perhaps the normally shorter crest. Monotypic.

Distribution. Extreme N Colombia (Guajira Peninsula) and N Venezuela (NW Zulia E through Falcón to SE Lara; NE Anzoátegui E to Sucre, including Margarita I).

Descriptive notes. 19 cm. Male has crown bright red, elongated crown feathers bright red at base with slightly darker tips; face and ear-coverts bright red, with narrow black band around bill base, often broader on chin and usually turning into an ill-defined dusky area over most of lores; upperparts duller red, becoming brighter red on rump; upperwing-coverts reddish-brown, edged with red, primaries brownish, outer webs broadly edged with red, rectrices dull red; throat and underparts bright red; iris brown; bill pale horn to pale bluish-grey, becoming dusky on tip and most of cutting edge; legs pale horn. Female has crown grey, elongated crown feathers bright red with dark shafts and grey-brown tips, side of head brownish, with whitish areas on side of forehead and below cheek, sometimes also some white around eye, loral area dusky, becoming blackish on a band of feathers around lower mandible, usually broader on chin; upperparts greyish-brown, becoming warmer brown on rump; remiges grey-brown, rosy tint towards base of primaries and on inner webs of secondaries and tertials; rectrices dull reddish-brown, fringed grey-brown; underparts cinnamon-buff; bill bluish-white, black tip of upper mandible, legs dusky horn. Juvenile similar to adult female but the brown is richer and more extensive. Voice. Song a pleasant series of loud whistled notes, "cheer o-weet-toweet toweet toweet" and so on, similar to that of *C. cardinalis* but slower and sweeter. Call note "chip".

Habitat. Inhabits semi-arid scrub with various cacti and spiny leguminous bushes. Absent from better-watered areas. Occurs from sea-level up to 300 m, occasionally up to 700 m in Lara (W Venezuela).

Food and Feeding. Few data recorded; of 80 emetic samples from Sucre (Venezuela), 83% contained invertebrate remains (six species identified), 48% fleshy fruits (ten species) and 84% seeds (six species). Forages singly and in pairs; occasionally in small groups. Searches in low vegetation, generally out of sight; frequently calls while foraging.

Breeding. Only six nests so far described, all on Margarita I. Season Jun to early Aug, with completed nests by mid-Jun and nestlings late Jul to early Aug; probably single-brooded. Nest a cup of vegetable matter, diameter 7–7·5 cm, located 0·5–1·4 m up in bush or prickly pear cactus (*Opuntia*). Clutch 3 eggs (four nests), once 4, eggs white with evenly distributed brown spotting; female alone incubates, no information on duration of period; small chicks brooded by female, young fed by both sexes, nestling period 12–13 days.

Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Caribbean Colombia and Venezuela EBA. Quite common in suitable habitat in some parts of range. Frequently captured for use as cagebird, at least in some areas; this poaching, where uncontrolled, undoubtedly has significant negative effect on populations.

Bibliography. Hilty (2003), Hilty & Brown (1986), Poulin *et al.* (1994), Ridgely & Tudor (1989), Rodríguez-Ferraro & Blake (2008), Rodríguez-Ferraro & Trujillo (2004), Salaman *et al.* (2008).

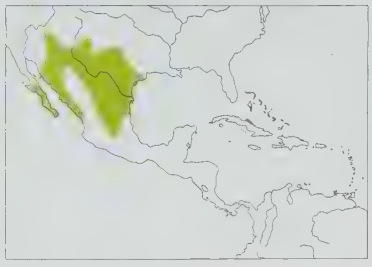
10. Pyrrhuloxia

Cardinalis sinuatus

French: Cardinal pyrrhuloxia **German**: Schmalschnabelkardinal **Spanish**: Cardenal Pardo

Taxonomy. *Cardinalis sinuatus* Bonaparte, 1838, western part of Mexico (Zacatecas).

Formerly placed in a monotypic genus, *Pyrrhuloxia*, mainly on account of its unique bill shape, very different from that of *C. cardinalis*; intermediate bill of *C. phoeniceus*, however, as well as other arguments, has resulted in its return to present genus. Three subspecies recognized.



Subspecies and Distribution.

C. s. fulvescens (van Rossem, 1934) – S USA (S Arizona) and NW Mexico (Sonora, Sinaloa and W Durango S to N Nayarit).

C. s. peninsulae (Ridgway, 1887) – extreme NW Mexico (Baja California S from c. 27° N).

C. s. sinuatus Bonaparte, 1838 – S USA (S New Mexico E to SE & C Texas) and S in C highlands and E lowlands of Mexico to NE Jalisco, Michoacán, Querétaro, San Luis Potosí and Tamaulipas.

Descriptive notes. 19–21·5 cm; male 30·1–44·2 g, females 24·4–43·2 g (Arizona). Has distinctive bill, with upper mandible short, thick and deep, with strongly curved culmen and strongly notched tomium, remarkably like that of a parrot (Psittacidae). Male nominate race has forehead, lores and area around eye deep rose-red, duskier red on narrow band around bill base, usually extending below eye and along a variably developed narrow malar line, crown grey, with a crest of deep rose-red feathers, ear-coverts grey; upperparts grey, rump greyish; primaries grey with broad pinkish-

rose edgings on outer webs (broad pinkish-rose patch on closed wing), secondaries greyish with diffuse pinkish on inner webs, shoulder pinkish-rose, carpal area bright rose; rectrices greyish-black with deep rose-red at base, especially at sides; chin and throat pinkish-red, chest pinkish-red in centre, becoming grey at side, pinkish-red broadens on belly, narrows on lower belly and becomes greyish-pink on vent; thigh bright pinkish-yellow; iris dark brown; bill yellow to orange in summer, horn-coloured or brownish with paler lower mandible in winter; legs dull light brown. Female is similar to male, but pink much reduced, being confined to forehead, lores and area around eye, and in crest; chin and throat indistinctly paler and pinkish, underparts greyish-buff, greyer at sides, with variable amount of pink in centre of lower chest; thigh pale pinkish-grey; pinkish area on closed wing much reduced and colour less strong, rectrices dull blackish-brown with dark rosy suffusions, especially at sides; bill as on male in summer, greyish-brown in winter. Juvenile usually lacks red in crest, has pale tips on wing-coverts (giving diffuse wingbar), bill dark grey, almost black. Race *fulvescens* is smaller-billed and longer-tailed than nominate, red areas paler and less deep in colour, little or no dusky on face, upperparts more brown in tone; *peninsulae* is slightly paler than previous, with shorter wing and tail. Voice. Song a series of whistles, usually of one syllable, sometimes more, "cheewee, cheewee" and so on, remarkably similar to, and sometimes indistinguishable from, that of *C. cardinalis*, but phrases tend to be shorter in length and less full and rich; in contrast to *C. cardinalis*, female sings only rarely, with more subdued song. The two species frequently have overlapping territories, but apparently do not defend them against each other; presence of nearby singing *C. cardinalis* may cause present species to sing with longer phrases. Calls include sharp metallic "chip" and high chattering "tic-tic-tic-tic". Food-begging young have longer "seep" call.

Habitat. Arid brushland, including mesquite (*Prosopis*) savanna, riparian woodland, various types of arid and semi-arid scrub; other favoured plant species are prickly pear (*Opuntia*), catclaw (*Acacia*) and whitebrush (*Aloysia gratissima*). High densities of hackberry (*Celtis*) and dense shrubs and vines not favourable for this species; suburban areas where habitat has been extensively modified have lower population densities (in contrast to situation with *C. cardinalis*). In winter months may wander into other areas not used for breeding, including open suburbs. Up to 1500 m In Arizona; sea-level to 2000 m in S Baja California.

Food and Feeding. In one study in Texas (USA) involving stomach contents, food c. 70% vegetable matter, 30% animal matter. Much of vegetable matter was seeds of grasses, nightshade (*Solanum*), spurge (*Euphorbia*) and similar, as well as cactus fruits. Animal items taken include grasshoppers (Orthoptera), caterpillars, beetles (Coleoptera), bugs (Hemiptera) and cicadas (Cicadidae). Visits saguaro cacti (*Carnegiea*) in bloom for nectar and pollen. Visits feeders, where seems to be subordinate to *C. cardinalis*. Will drink water when available, but much of water needs apparently supplied by food. In winter forms loose flocks with other species, including *C. cardinalis*. Forages on ground and in vegetation.

Breeding. Eggs Mar–Aug in Texas and to Sept in Arizona, in both cases majority in May; apparently predominantly single-brooded, but some cases of double-brooding (as opposed to replacement of failed clutches) in Arizona. Territory size may vary, 0·6–8 ha (average c. 1·5 ha) in one Texas study. Nest built mainly or entirely by female, a small compact oval cup made from thorny twigs, strips of bark and coarse grass, lined with rootlets, spider webs, feathers and fine fibres, external dimensions c. 9–11 × 6–9 cm, cup c. 7·5 × 4–6 cm (usually somewhat smaller than nest of *C. cardinalis*), placed in brush or hedgerow, in mesquite or in one of numerous other species, in studies in Arizona and Texas average height above ground 2·4 m and 3–4 m, respectively. Clutch 2–4 eggs, rarely 5, average 3·2 in Arizona and 3·4 in Texas, greyish-white to greenish-white, with quite heavy brownish markings overlaid on grey; incubation by female alone, sometimes fed on nest by male, period 14 days; small chicks brooded by female, young fed by both sexes, apparently more by female, nestling period 10–13 days; on leaving nest young fly very poorly, cared for by both parents for several days further; thereafter, young join flocks and may be more mobile. Nests sometimes parasitized by Brown-headed Cowbird (*Molothrus ater*) and Bronzed Cowbird (*Molothrus aeneus*), e.g. in one Texas study 13% of nests had cowbird eggs or young. Cowbirds apparently have significant effect on nest success of this species, perhaps more than on that of *C. cardinalis*.

Movements. Resident; may wander locally outside breeding season, but no ringing recoveries of more than 20 km. Several extralimital records in USA in Colorado, SW Kansas and W Oklahoma; reports from Nevada disputed.

Status and Conservation. Not globally threatened. Quite common in suitable habitat in USA; uncommon to fairly common in Mexico. Densities in Texas 10–80 individuals/40 ha, in Arizona, 6–8/40 ha. Densities in suburbs, even when much native vegetation remains, much lower. May have benefited from colonization of former grass rangeland by mesquite.

PLATE 36 ➤

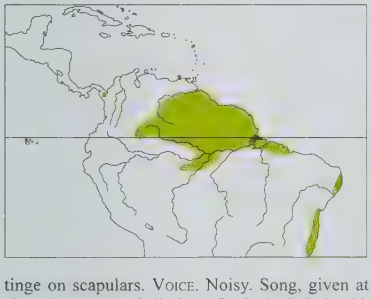
Genus *CARYOTHRAUSTES* Reichenbach, 1850

11. Black-faced Grosbeak

Caryothraustes poliogaster

French: Cardinal à ventre blanc **German**: Graubauchkardinal **Spanish**: Picogrueso Carinegro
Other common names: Bishop Grosbeak

Taxonomy. *Pitylus poligaster* du Bus de Gisignies, 1847, Guatemala.
May form a superspecies, and has been treated as conspecific, with *C. canadensis*. Race *simulans* of latter sometimes included in present species. Two subspecies recognized.
Subspecies and Distribution.
C. p. poliogaster (du Bus de Gisignies, 1847) – Caribbean lowlands of Mexico (from C Veracruz, NE Oaxaca and N Chiapas E to S Quintana Roo), N Guatemala, Belize and N Honduras.
C. p. scapularis (Ridgway, 1888) – Caribbean lowlands from E Honduras and Nicaragua S to Panama (Bocas del Toro, Veraguas and Coclé; formerly, or casually, farther E).
Descriptive notes. 18–19 cm; 34·9–46·7 g (nominate). Nominate race has forehead yellow, becoming yellow-green on crown and nape, duller dark greenish-yellow on mantle and back, variable



amount of grey on scapulars, and greyish-green lower back and rump; shoulder and upperwing-coverts dull dark greenish-yellow, primaries and secondaries dull blackish-grey with broad greenish edgings on outer webs (giving greenish appearance to closed wing); rectrices dull dark greenish; lowermost forehead, lores, area around eye, chin and upper throat black, ear-coverts and chest deep yellow, rest of underparts medium-grey; carpal area and underwing-coverts bright yellowish-green; iris dark brown; bill blackish, grey base; legs blue-grey. Sexes similar. Juvenile has facial mask much less clearly defined and grey-black, is generally duller than adult. Race *scapularis* is similar to nominate, but smaller, with scapulars and lower back yellowish olive-green. Voice. Noisy. Song consists of 3–6 mellow but sharp whistles, "cher-che weet, cher-che weet"; also alternating with shorter version, sometimes followed by sharp, downwardly inflected whistles. Female sings, but songs shorter. Calls include buzzy "zzzrt" and a quiet "pit" in flight.
Habitat. Humid lowland evergreen forest and forest edge; sea-level to 1200 m in Mexico, to 900 m in Costa Rica.
Food and Feeding. Food items both vegetable and animal: fruits of Mexican rubber tree (*Castilla*), berries of *Hamelia*, *Bactris*, seeds and pulp of *Stemmadenia*, the epiphytic cactus *Rhipsalis*, *Ficus pertusa*, small arillate seeds; arthropods, including caterpillars and occasionally flying insects. Gregarious; often found in noisy flocks of up to 20 individuals, often mixed with other species, moving through upper and middle levels of forest.
Breeding. Season mainly Apr–Jun; birds in breeding condition early Mar to late May in Belize. From limited observations appears to be co-operative nester, up to four birds in adult-type plumage attending nest and defending young, although several more may be involved peripherally; relationship of helpers to breeding pair not known. Nest a slight shallow bowl c. 7·5 cm in diameter, outer layer of fern rhizomes with green leaves still attached, middle layer of dead leaves, and lining of long leaves of epiphytic bromeliad *Tillandsia* coiled down into bowl while fresh and pliant, placed 3–6 m above ground in small tree or palm. Clutch 3 eggs, dull white, mottled and spotted all over, especially at blunt end, with bright shades of brown (reports that eggs are unmarked yellow-green seem to be erroneous); incubation probably by female alone, sitting female occasionally sings from nest, incubation period 13–13·5 days; chicks fed by both parents, also by one or more helpers if present (sex of helpers not known; in some studies sometimes additional birds attended, but did not feed young), nestling period 11–12 days.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Quite common to common in suitable habitat in much of range. Prefers undisturbed habitat.
Bibliography. Cant (1979), Howell & Webb (1995), Moermond (1981), Ridgely & Gwynne (1989), Ridgway (1888), Russell (1964), Schönwetter & Meise (1981), Skutch (1972, 1989a), Vu Halinh *et al.* (2007).

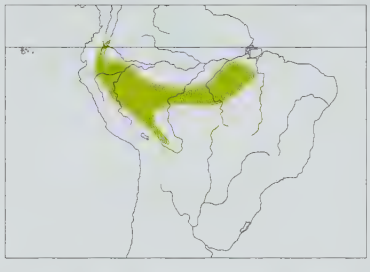
12. **Yellow-green Grosbeak**

Caryothraustes canadensis

French: Cardinal flavert **German**: Gelbbauchkardinal **Spanish**: Picogrueso Verdiamarillo
Other common names: Green Grosbeak

Taxonomy. *Loxia canadensis* Linnaeus, 1766, Canada; error = Cayenne, French Guiana.
May form a superspecies, and has been treated as conspecific, with *C. poliogaster*. Race *simulans* sometimes included in latter species. Four subspecies recognized.
Subspecies and Distribution.
C. c. simulans Nelson, 1912 – Cerro Pirré (E Darién), in E Panama.
C. c. canadensis (Linnaeus, 1766) – SE Colombia (Vaupés), S Venezuela (Amazonas, Bolívar, Delta Amacuro), the Guianas and N Brazil (E Amazonas and N Pará E to N Maranhão).
C. c. frontalis (Hellmayr, 1905) – NE Brazil (Paraíba, Pernambuco and Alagoas).
C. c. brasiliensis Cabanis, 1851 – EC Brazil (E Bahia, E Minas Gerais, Espírito Santo and Rio de Janeiro).

Descriptive notes. 17–18·5 cm; 31–36 g; 15 cm (*simulans*). Nominate race has top of head and entire upperparts, including rectrices and remiges, yellowish-green, remiges with yellow edgings on inner webs; lores down to cheek and throat black; underparts bright yellow, chest and flanks slightly greenish-tinged yellow; iris brown; bill black, base blusih-grey; legs grey. Sexes similar. Juvenile undescribed. Race *frontalis* is similar to nominate, but has black frontal band on mask; *brasiliensis* is larger than nominate, with brighter yellow forecrown; *simulans* is paler above than nominate, with variable greyish tinge on scapulars. Voice. Noisy. Song, given at dawn, a lively, continuous, monotonous "chap chap cheeweep". Calls from flocks include loud buzzy "dzzeet", repeated "chew-chew-chew" and others.
Habitat. Lowland humid forest and forest borders, especially in areas of high rainfall; sea-level to 1000 m on tepui foothills in Venezuela, mostly below 250 m in Colombia. Race *simulans* occurs in humid forest at 250–1250 m.
Food and Feeding. Diet mixed animal and vegetable; in Suriname, stomach contents included beetles (Coleoptera), cockroaches (Blattodea) and their oothecae, and berries. Occurs in flocks of a dozen or more individuals; commonly joins mixed-species foraging flocks. Forages in canopy and down to middle levels of wet forest.
Breeding. Young being fed at nest in late Mar and late Nov in French Guiana, nest in Jan in Brazil (near Manaus), and pair building nest in Feb in Colombia; birds in breeding condition in Feb–Apr in Venezuela and Brazil. One nest described (near Manaus), an untidy cup built from bark strips, located 7 m up in tree; nest being built in Colombia was 7–8 m up in base of palm frond. Clutch 2 eggs, cream-coloured with scattered brown spots, especially around blunt end (also unverified report of 2–3 eggs, bluish-white with brown markings). No other information.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Fairly common in suitable habitat in much of range. Race *simulans* has very restricted geographical distribution in Darién, in E Panama; was thought to be restricted to Cerro Pirre, but recent records from Serrania de Jungurundú, farther S in Darién.
Bibliography. Angehr *et al.* (2004), Borges & Cardoso (1995), Haverschmidt (1968), Hilty (2003), Hilty & Brown (1986), Nelson (1912), Ridgely & Gwynne (1989), Robbins *et al.* (1985), Salaman *et al.* (2008), Sick (1993), Tostain *et al.* (1992).



Genus *PARKERTHRAUSTES* Remsen, 1997

13. **Yellow-shouldered Grosbeak**

Parkerthraustes humeralis

French: Cardinal à épaulettes **German**: Gelbschulterkardinal **Spanish**: Picogrueso Humeral

Taxonomy. *Pitylus (Caryothraustes) humeralis* Lawrence, 1867, "Bogotá, Colombia" (trade skins of unknown provenance).
Relationships uncertain; has been suggested as belonging in tanager family (Thraupidae), but true taxonomic position not known. Formerly placed in genus *Caryothraustes*, but differs significantly in morphology (e.g. bill shape, notched tail), plumage (including sexual dimorphism) and behaviour (quiet, inconspicuous, and solitary or in pairs), as well as genetically; subsequently placed in its own monotypic genus. Taxonomic status of undescribed form from Ecuador as yet unclear. Monotypic.
Distribution. Extreme S Colombia (E slope of Andes in Caquetá and Putumayo), E Ecuador (E slope from W Sucumbíos and W Napo S to Morona-Santiago), E Peru (Amazonas and Loreto S to Madre de Dios and N Puno), SW & C Brazil (S Amazonas and Rondônia E to S Pará and NW Mato Grosso) and N Bolivia (La Paz and Cochabamba).

Descriptive notes. 16 cm; one female 37 g (Brazil). Distinctive, with relatively narrow bill thick-based and with strongly curved culmen. Male has crown to nape grey, lores, area below eye and ear-coverts blackish; upperparts greenish-yellow, flight-feathers blackish, broadly edged greenish-yellow on outer webs, tertials blackish on inner webs; yellow on shoulder and carpal area; rectrices are mainly dull greenish-yellow with dark inner webs; submoustachial area to chin and throat scalloped whitish and dull black, with blackish malar stripe; chest grey, becoming paler on belly, vent bright yellow; iris red; upper mandible black, lower mandible grey; legs grey. Birds of undescribed form from Ecuador are more robust, with thicker bill, broader black mask and extensive black on throat, as well as showing somewhat more yellow on bend of wing. Female has crown and nape dull grey, contrasting with greenish-yellow back, lower rump yellow, rectrices dull greenish-yellow, darker on inner webs; shoulder patch and carpal area bright yellow, flight-feathers dull blackish with yellow-green outer webs, primary coverts and alula grey-black; lores and ear-coverts grey-brown; chin and throat scalloped grey and greyish-black, narrow black malar stripe; chest and belly greyish, belly with greenish tinge, vent and thigh bright yellow; bare parts as for male. Juvenile is similar to adult, but duller. Voice. Rather silent. Song a repetitive, high lisping "seet tseer-tseer"; call a loud, clear inflected "suweet". Dependent young have high-pitched begging call.
Habitat. Interior of lowland humid forest, at 200–1000 m; usually below 750 m.
Food and Feeding. No published data; stomach contents (Ecuador) insect parts and seeds. Solitary and in pairs, often in mixed-species foraging flocks with tanagers. Forages in canopy; gleans insects from foliage, especially near ends of branches.
Breeding. Juveniles seen when foraging with adults in Jun in NE Peru. No other information.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Not well known. Evidently rather uncommon and in low numbers through much of range; possibly overlooked owing to its inconspicuous behaviour. May be more common than it appears, at least locally; apparent scarcity likely due to some extent to lack of observations.
Bibliography. Demastes & Remsen (1994), Hilty & Brown (1986), Parker (1982), Remsen (1997b), Remsen & Ridgely (1980), Ridgely & Greenfield (2001a), Ridgely & Tudor (1989, 2009), Schulenberg & Remsen (1982), Schulenberg *et al.* (2007), Tamplin *et al.* (1993).

Genus *RHODOTHRAUPIS* Ridgway, 1898

14. **Crimson-collared Grosbeak**

Rhodothraupis celaeno

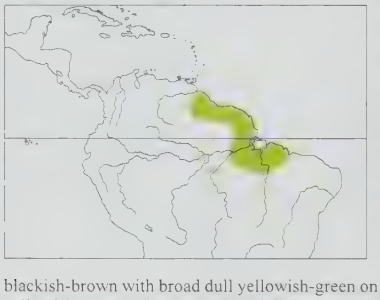
French: Cardinal à collier **German**: Halsbandkardinal **Spanish**: Picogrueso Acollarado

Taxonomy. *Tanagra Celaeno* W. Deppe, 1830, Papantla, Veracruz, Mexico.
Closely affiliated with *Periporphyrus*. Monotypic.

On following pages: 15. Red-and-black Grosbeak (*Periporphyrus erythromelas*); 16. Slate-colored Grosbeak (*Saltator grossus*); 17. Black-throated Grosbeak (*Saltator fuliginosus*); 18. Black-headed Saltator (*Saltator atriceps*); 19. Buff-throated Saltator (*Saltator maximus*); 20. Black-winged Saltator (*Saltator atripennis*).

Distribution. Atlantic slope of NE Mexico from C Nuevo León, S Tamaulipas and E San Luis Potosí, S to Querétaro, Hidalgo, NE Puebla and N Veracruz.

Descriptive notes. 21–22 cm; one female 60 g. Male has crown, face, ear-coverts, chin, throat and upper chest black, nape dark crimson, mantle deep dull crimson, back and rump black with dull crimson feather edges; upperwing blackish, wing-coverts with very fine dark crimson edges; rectrices dull black; underparts dark crimson, some black mottling in centre of chest; iris brown; upper mandible pale blue-grey with blackish tip and on cutting edge, lower mandible blackish with pale blue-grey base; legs grey. Female is essentially similar to male, but all crimson areas replaced by olive on upperparts and by olive-yellow on underparts, and wing and tail olive-green; bill blackish, with blue-grey base of lower mandible. Immature male has dark crimson of adult replaced by dull olive-yellow, belly with extensive black mottling; immature female has face and throat black, but chest sooty grey. Voice. Song a rich to slightly burry warble, often upslurred at end; somewhat similar to that of *Pheucticus ludovicianus*, but with fewer curved or warbled notes. Calls include high, clear, penetrating slurred "sseeuu" or "sseeeur", also a piercing "seeip seeeiyu".
Habitat. Humid to semi-arid brushy woodland and edge, second growth; also citrus groves and sweet gums (*Liquidambar*). Sea-level to c. 1200 m.
Food and Feeding. Frequently folivorous; stomach contents (Tamaulipas) chewed-up leaves of nightshade (*Solanum verbascifolium*), also some insects, but no seeds. Opportunistically feeds on fruit in citrus groves; also various other fruits such as mangos (*Mangifera*), loquat (*Eriobotrya japonica*), chinaberry (*Melia azedarach*) etc. Vagrants in Texas (S USA) seen to eat various fruits, including apple and citrus, and leaves of several plants, including potato tree (*Solanum erianthum*). Found singly and in pairs; joins mixed-species flocks. Forages at all levels in forest, sometimes descending to ground.
Breeding. Nest found in May. Apparently only one nest so far described, a loosely constructed cup of twigs, thinly lined and not deep, located 2 m up in tangle of vines and shrubbery. Clutch 2–3 eggs, pale bluish-grey with light brown spots all over; young apparently tended by female alone; no other information.
Movements. Apparently sedentary. Some movement or wandering; numerous records in S Texas (S USA), 200 km and more N of normal range; some of these vagrants established territories.
Status and Conservation. Not globally threatened. Restricted-range species: present in North-east Mexican Gulf Slope EBA. Fairly common to uncommon over much of range. Appears able to adapt to some habitat modification.
Bibliography. Braun & Emanuel (1982), Eitniear (2006b), Eitniear & Tapia (2000), González-García *et al.* (2009), Howell & Webb (1995), Sutton (1950), Sutton *et al.* (1950), Webster (1974).



Genus *PERIPORPHYRUS* Reichenbach, 1850

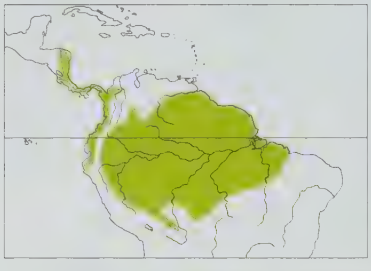
15. **Red-and-black Grosbeak**

Periporphyrus erythromelas

French: Cardinal érythromèle **German**: Schwarzkopfkardinal **Spanish**: Picogrueso Rojinegro

Taxonomy. *Loxia erythromelas* J. F. Gmelin, 1789, Cayenne, French Guiana.
Closely affiliated with *Rhodothraupis*. Monotypic.
Distribution. Extreme E Venezuela (E Bolívar, E Delta Amacuro), N & C Guyana, Suriname (except extreme SW), French Guiana, and N Brazil (Amapá S to E Pará and N & W Maranhão; also isolated in NE Amazonas and W Pará).

Descriptive notes. 20·5 cm; one male 48 g. Male has entire head, chin and throat black; red nape collar separating black of head from deep reddish of upperparts; wing-feathers blackish-brown with reddish-brown outer webs; rectrices dull reddish; chest and belly bright red, becoming slightly duller on vent; iris dark brown, black or blue-black; bill black, lower mandible silver-grey or pale blue-grey with black on distal portion and along cutting edge; legs dark greyish-black or pinkish-grey. Female has crown and face to throat dull black; upperparts dark greenish-yellow, fine darker streaks on nape; primaries and secondaries blackish-brown with broad dull yellowish-green on outer webs (giving closed wing an overall dark yellowish-green colour); rectrices dull dark greenish-brown; underparts yellowish-green, diffusely mottled darker, some females (presumably older ones) having large orange-red flecks on underparts; bare parts similar to those of male. Immature male is generally duller than adult, with head dull black, underparts orange-red, borders of black on throat less clear-cut. Voice. Song an exceptionally sweet series of halting phrases that slide up and down, given slowly with pauses; typically consists of variations built around 2–3 standard phrases. Both sexes sing. Call a high-pitched, sharp "spink".
Habitat. Mature lowland humid forest, *terra firme*, also seasonally flooded forest; sea-level to 1000 m.
Food and Feeding. Little published information; stomach contents of one specimen described as arthropods, of another insects 40% and seeds 60%. In pairs and family groups; does not, apparently, join mixed-species flocks. Forages in shady lower levels of forest, occasionally into subcanopy; often wary.
Breeding. No information.
Movements. Apparently sedentary; ranges widely within its territory.
Status and Conservation. Not globally threatened. Almost always rare and at low density and in small numbers throughout its range. Rare in French Guiana. Not recorded in Suriname until 1972, although now regular in Brownsberg Reserve. Appears not to adapt to man-modified habitats.
Bibliography. Davis (1979), Fernandes (2007), Henriques *et al.* (2003), Hilty (2003), Mees (1974), Ridgely & Tudor (1989, 2009), Stotz *et al.* (1996), Thiollay (2002), Tostain *et al.* (1992).



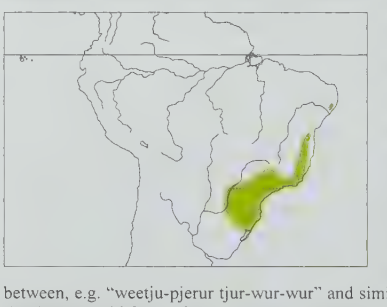
Genus *SALTATOR* Vieillot, 1816

16. **Slate-colored Grosbeak**

Saltator grossus

French: Saltator ardoisé **German**: Rotschnabelsaltator **Spanish**: Pepitero Pizarroso
Other common names: White-throated/Slaty Grosbeak

Taxonomy. *Loxia grossa* Linnaeus, 1766, Cayenne, French Guiana.
Affiliations of genus uncertain; recent molecular-genetic analyses indicate that it does not belong with present family, and may be better placed with tanagers (Thraupidae). Present species and *S. fuliginosus* sometimes treated as conspecific, and both sometimes placed in a separate genus, *Pitylus*. Two subspecies recognized.
Subspecies and Distribution.
S. g. saturatus (Todd, 1922) – E Honduras, Nicaragua, Caribbean slope of Costa Rica, Panama (Caribbean slope, and E from Veraguas on Pacific slope), NW Colombia (W of Andes) and W Ecuador (S to W Loja and El Oro).
S. g. grossus (Linnaeus, 1766) – SE Colombia E of Andes (S from Vichada), S Venezuela (Amazonas, Bolívar), the Guianas, N Brazil (S to N Mato Grosso and Maranhão), E Ecuador (Sucumbíos S to Zamora-Chinchipe), E Peru and N Bolivia (Beni and NW Santa Cruz).



Descriptive notes. 19–20·5 cm; 41–53 g (Venezuela and Suriname). Male nominate race is mostly uniformly slaty blue above and below; lores, area below eye, anterior ear-coverts and malar region, side of throat and chestband black, chin and centre of throat white; upperwing and tail blackish, secondaries with slate-blue edgings on outer webs, wing-coverts broadly edged slate-blue; underwing-coverts white; iris deep brown; bill bright orange-red or red; legs dark horn or brownish-grey or black. Female is generally duller than male, more greenish-slate below, black around throat duller or absent, centre of throat grey-white with less contrast. Immature is generally much duller than adult, with chin–throat patch dull greyish-white and reduced in extent. Race *saturatus* is very like nominate, but slightly darker overall. Voice. Song an arresting series of 3–7 loud, rich whistles, e.g. "twee-tee-wee-teewee-chee-cher" , often likened to that of Rufous-browed Peppershrike (*Cyclarhis gujanensis*); individuals sing several variants of each song type, also a softer, quicker version. Calls include *Cardinalis*-like "peet" and nasal whine.
Habitat. Humid forest, forest borders, and mature secondary woodland; in South America both *várzea* and *terra firme*. Sea-level to 1200 m, occasionally to 1700 m.
Food and Feeding. Recorded food items seeds and arthropods; insects including beetles (Coleoptera). Usually in pairs, sometimes with other species in mixed foraging flocks. Forages in canopy and middle to upper levels of forest.
Breeding. Recently fledged young in mid-May in Costa Rica; in Colombia, birds in breeding condition in Mar–Apr (Chocó), May (S Córdoba) and Sept (Santander). Nest cup-shaped, made from grasses, roots, dry leaves and similar, lined with finer vegetation and rootlets. Clutch 2–3 eggs, bluish-white marked with brown. No other information.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Fairly common in suitable undisturbed habitat.
Bibliography. Demastes & Remsen (1994), Haverschmidt (1968), Hilty (2003), Hilty & Brown (1986), Ridgely & Greenfield (2001a), Tamplin *et al.* (1993).

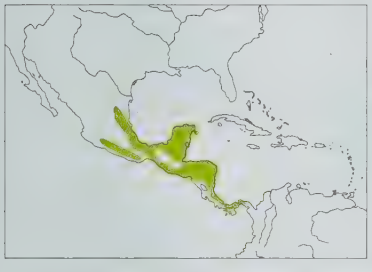
17. **Black-throated Grosbeak**

Saltator fuliginosus

French: Saltator fuligineux **German**: Papageischnabelsaltator **Spanish**: Pepitero Fuliginoso

Taxonomy. *Loxia fuliginosa* Daudin, 1800, Rio de Janeiro, Brazil.
Affiliations of genus uncertain; recent molecular-genetic analyses indicate that it does not belong with present family, and may be better placed with tanagers (Thraupidae). Present species and *S. grossus* sometimes treated as conspecific, and both sometimes placed in a separate genus, *Pitylus*. Monotypic.
Distribution. E Brazil (Alagoas; S Bahia and E Minas Gerais S to N Rio Grande do Sul) and NE Argentina (Misiones); possibly also SE Paraguay (no recent records).

Descriptive notes. 22 cm. Male has crown and upperparts deep slate-blue, wing-feathers dull black with deep slate-blue edges, tail more uniform dull black; lores, face, ear-coverts, throat and mid-breast black, lower breast, belly and flanks deep slate-blue; underwing-coverts white; iris dark brown; bill bright coral-red; legs dark grey. Female is generally duller than male, with less of a blue tinge on upperparts, less contrast between chest and belly. Juvenile is generally duller, and rather less blue, than adult, may have darker ridge of the culmen. Voice. Song is a loud series of whistles, often delivered in two parts with long interval in between, e.g. "weetju-pjerur tjur-wur-wur" and similar.
Habitat. Humid forest, from sea-level to 1200 m; largely montane in N part of range.
Food and Feeding. No published data available on diet. Forages in middle and upper levels of forest; occasionally lower.



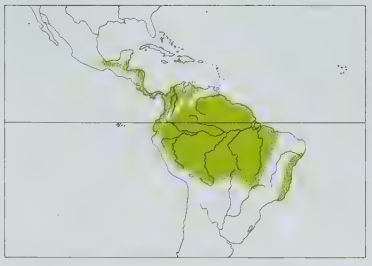
Breeding. Nest undescribed; eggs stated to be uniformly clear greenish-blue; frequently parasitized by Shiny Cowbird (*Molothrus bonariensis*). No other information.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Uncommon. Not well known. In E Paraguay recorded in early decades of 20th century in Alto Paraná, but no records since then. Much of this species' original habitat has been destroyed for agriculture or development.
Bibliography. van Perlo (2009), Ridgely & Tudor (1989, 2009), Schönwetter & Meise (1981), Sick (1993), Steullet & Deautier (1940).

18. Black-headed Saltator

Saltator atriceps

French: Saltator à tête noire **German**: Schwarzkappensaltator **Spanish**: Pepitero Cabecinegro

Taxonomy. *Tanagra (Saltator) atriceps* Lesson, 1832, Veracruz, Mexico.
Affiliations of genus uncertain; recent molecular-genetic analyses indicate that it does not belong with present family, and may be better placed with tanagers (Thraupidae). Six subspecies recognized.
Subspecies and Distribution.
S. a. atriceps (Lesson, 1832) – Caribbean slope of Mexico from S Tamaulipas S (except SE Veracruz and N & C Yucatán Peninsula) to E Costa Rica.
S. a. suffuscus Wetmore, 1942 – Sierra de Tuxtla, in SE Veracruz (E Mexico).
S. a. raptor (S. Cabot, 1845) – SE Mexico (Campeche, Yucatán and Quintana Roo).
S. a. flavicrissus Griscom, 1937 – Guerrero E to C Oaxaca, in SW Mexico.
S. a. peeti Brodkorb, 1940 – Pacific slope of E Oaxaca and Chiapas, in S Mexico.
S. a. lacertosus Bangs, 1900 – E Costa Rica (Talamanca) and Panama (E to Canal Zone; one record in Darién).



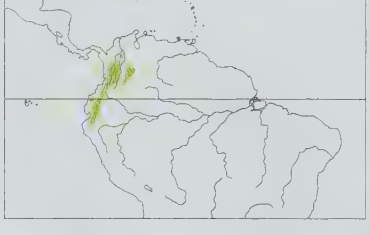
Descriptive notes. 24 cm; 63–116 g (El Salvador), 68·2–91·2 g (Yucatán). Nominate race has crown black, face blackish, white supercilium and greyish submoustachial area; upperparts, including upperwing-coverts and tail, copper-green, rectrices brighter on outer webs; primaries darker grey-black with copper-green edgings; chin black, large white throat patch bordered with black on all sides, including broad black breastband; lower breast and belly grey, flanks tinged olive, vent and undertail-coverts cinnamon; iris deep reddish-brown; bill black; legs slate-grey. Sexes alike. Juvenile is similar to adult, but black areas more sooty, throat patch dull whitish and less contrasting. Race *suffuscus* has throat patch cinnamon, not white; *flavicrissus* is similar to nominate, but pectoral band broader, white throat patch smaller, flanks less brown or olive, vent more ochraceous; *peeti* is similar to nominate, but larger; *raptor* is similar to previous, but still larger; *lacertosus* is similar to nominate, but greyer on side of head, breastband narrow or absent. Voice. Song a loud series of cackling, scratchy squawks, ending in prolonged upwardly inflected whistle; both sexes sing, often in duet. Also a high, thin dawn song, "tseety-tseety-tseety". Calls loud and raucous.
Habitat. Second growth, regenerating pastures, well-vegetated gardens, thickets. Sea-level to 1800 m in Mexico, to 1200 m in Costa Rica.
Food and Feeding. Recorded food items include small fruits and seeds, flowers and tender buds; also insects. On one occasion seen to take a hummingbird (Trochilidae) captured in a net, eating part of head. Usually found in flocks, sometimes in association with other species.
Breeding. Breeding recorded end of May in Mexico, and season Apr–Jul in Costa Rica. Nest a bulky, shallow cup of grass, strips of banana leaves and the like, on loose foundation of twigs, lined with finer vegetable matter, placed 1·5–3 m up in bush. Clutch 2 eggs, pale blue, marked with heavy black scrawls around blunt end. No other information.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Quite common in suitable habitat over much of its range. Takes advantage of second growth and abandoned farmland.
Bibliography. Armani (1983), Brodkorb (1940), Clark (1913b), Howell & Webb (1995), Komar & Thurber (2003), Ridgely & Gwynne (1989), Stiles & Skutch (1989), Sutton *et al.* (1950), Wetmore (1942, 1943).

19. Buff-throated Saltator

Saltator maximus

French: Saltator des grands-bois **German**: Buntkehlsaltator **Spanish**: Pepitero Gorjicanelo

Taxonomy. *Tanagra maxima* Statius Müller, 1776, Cayenne, French Guiana.
Affiliations of genus uncertain; recent molecular-genetic analyses indicate that it does not belong with present family, and may be better placed with tanagers (Thraupidae). Some races have been considered perhaps to merit treatment as separate species, but an orderly geographical sequence of characters across the species' range is apparent. Five subspecies recognized.
Subspecies and Distribution.
S. m. gigantodes Cabanis, 1851 – Caribbean slope of Mexico from Veracruz S to N Oaxaca and Tabasco.
S. m. magnoides Lafresnaye, 1844 – S Mexico (Chiapas, S Campeche, S Quintana Roo) N Guatemala and Belize S on Caribbean slope to Nicaragua, Costa Rica and NW Panama.
S. m. intermedius Lawrence, 1864 – SW Costa Rica E to Canal Zone of Panama.
S. m. iungens Griscom, 1929 – E Panama and NW Colombia (E to lower R Cauca).
S. m. maximus (Statius Müller, 1776) – Colombia and Venezuela E to the Guianas, S to W & E Ecuador, E Peru, Brazil (Amazonia S to S Mato Grosso; also E coast from Pernambuco S to Rio de Janeiro) and NE Bolivia (Beni and Santa Cruz).
Descriptive notes. 20·5–21 cm; male average 46·2 g, female average 49·1 g (Panama). Nominate race has crown greenish-grey, becoming more bright greenish on nape and upperparts, including upperwing and tail; supercilium greyish-white, ear-coverts grey, broad black malar stripe; chin white, becoming buffy on throat and grey on chest; belly more tinged cinnamon; iris dark brown; bill greyish-horn or blackish-horn; legs leaden grey. Sexes alike. Juvenile has facial markings less sharply defined, malar stripe duller, upperparts tinged brownish, and paler bill. Race *gigantodes* differs clearly from nominate,



with malar stripe extending into broad black chestband, crown mostly blackish; *magnoides* similar to previous but crown less black, intermediate in colour between previous and nominate; *intermedius* is similar to previous, but brighter grey on crown, buff throat patch paler and broader, black chestband narrower or entirely absent; *iungens* is similar to nominate, but generally duller and less golden-green on upperparts, with yellower crissum. Voice. Song varies throughout range: in Costa Rica, a loud series of melodious, soft lilting notes, e.g. "cheery-cheery" etc.; in Venezuela, a pleasing if repetitive carolling, reminiscent of *Turdus* thrushes. Also has softer, quieter song. Female sings (including when incubating) with shorter and quieter song than that of male. Call a quiet, high sibilant "tsii".
Habitat. Semi-humid and humid forest edge, second growth, sometimes well-bushed suburbs, shade coffee plantations, regenerating farmland and similar; sea-level to 1800 m.
Food and Feeding. Predominantly vegetarian: fruit, blossoms, catkins, berries, fresh leaves, etc.; comes to eat bananas at feeding stations. Some insects, mainly hymenopterans; has been seen to feed systematically on the army ant *Eciton burchelli*. Found singly and in pairs; regularly associates with mixed-species feeding flocks, including those with *S. atripennis*. Forages at all levels, mostly high up in trees.
Breeding. Season Mar–Aug in Costa Rica, one nest in Apr in Panama, nest under construction in early Dec in French Guiana, and nests found in Jun and Aug and birds in breeding condition Jan–Jun in Colombia; at least two broods in some areas. Nest apparently built by female alone, a bulky open cup made from coarse twigs and leaves, leaf vanes, dead vines and the like, lined with finer material, placed at 0·3–2 m, rarely as high as 10 m, in bush or tree. Clutch usually 2 eggs, 3 recorded in Guyana, bright pale blue, with dots, splotches and scrawls of black around blunt end; incubation apparently by female alone, sometimes fed on nest by male, period 13–14 days, occasionally longer; small chicks brooded by female alone, fed by both parents, nestling period c. 13–15 days; fledglings attended by both parents until 50–55 days old.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Generally common over much of its range. In NE Brazil, one record in Piauí. Tolerates modified habitats well.
Bibliography. Hallinan (1924), Haverschmidt (1968), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995), Kirmse (1969), Novaes (1992), Ridgely & Greenfield (2001a), Russell (1964), Sealy *et al.* (1997), Skutch (1954), Stiles & Skutch (1989), Stotz (1992), Tostain *et al.* (1992).

20. Black-winged Saltator

Saltator atripennis

French: Saltator à ailes noires **German**: Schwarzschwingensaltator **Spanish**: Pepitero Alinegro

Taxonomy. *Saltator atripennis* P. L. Sclater, 1857, Popayán, Colombia.
Affiliations of genus uncertain; recent molecular-genetic analyses indicate that it does not belong with present family, and may be better placed with tanagers (Thraupidae). Races of present species weakly differentiated and differences possibly not constant; species perhaps better treated as monotypic. Two subspecies tentatively recognized.
Subspecies and Distribution.
S. a. atripennis P. L. Sclater, 1857 – Colombia (both sides of W Andes and W slope of C Andes from Antioquia S to Nariño) and extreme NW Ecuador (W Esmeraldas).
S. a. caniceps Chapman, 1914 – disjunctly on W slope of E Andes of Colombia (Boyacá, Cundinamarca) and W Ecuador.

Descriptive notes. 20·5 cm; 44–60 g (Colombia). Nominate race has crown, ear-coverts and malar region black (crown sometimes grey), broad white supercilium, patch at rear of ear-coverts white; upperparts bright olive-green, upperwing and tail contrastingly dull black, tertials (often also greater coverts) diffusely edged with greenish; chin and throat white, often with buff wash over lower throat and central chest, breast dove-grey, belly grey-white, lower areas tinged greenish at side, vent orange-buff; iris orange or brown; bill blackish; legs grey or brown. Sexes alike. Juvenile is generally duller than adult, back less bright green, facial markings less clear-cut, chest diffusely mottled grey and whitish, bill grey, iris brown. Race *caniceps* is similar to nominate, but crown largely grey (instead of black), exposed portion of tertials wholly olive-green, no buffy wash on throat or breast, undertail-coverts paler, bill heavier. Voice. Song in Ecuador a leisurely series of slurred notes with long pauses, rising and falling in pitch, somewhat like that of a New World oriole (*Icterus*), "twee, twaa, too-u, toweer, tweeear" and so on, followed by a jumble of spluttered notes; in SW Colombia (W Nariño), a descending note and then quavering and rising one, "cheeeear, tre-e-e".
Habitat. Humid or wet forest and forest borders, also mature second growth, generally rather wet. Mostly 500–1500 m, locally down to 50 m and up to 1700 m, in Ecuador; in Colombia mostly 800–2200 m, on Pacific slope down to 400 m.
Food and Feeding. No published details of diet; apparently fruit. Often in mixed-species feeding flocks with other species, including *S. maximus*. Forages in upper levels and canopy.
Breeding. Nest-building observed in mid-Apr in Colombia; in Ecuador, nest with young in mid-Dec and adults carrying nesting material in Feb. Nest a deep cup made from roots, mosses, leaves and similar, lined with grasses and finer fibres; one under construction in Colombia was low down in pasture bush. Clutch 2–3 eggs, blue or greenish with brownish-black markings. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common in suitable habitat in Colombia; uncommon to locally fairly common in Ecuador.
Bibliography. Armani (1983), Chapman (1914b), Greeney & Nunnery (2006), Hilty & Brown (1986), Ridgely & Greenfield (2001a), Ridgely & Tudor (1989).

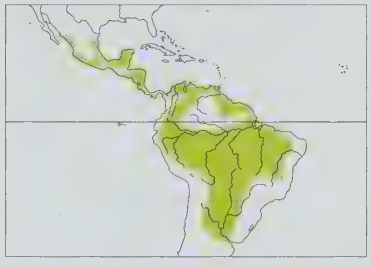
21. Green-winged Saltator

Saltator similis

French: Saltator olive **German**: Grünschwingensaltator **Spanish**: Pepitero Verdoso
Other common names: Allied Saltator

Taxonomy. *Saltator similis* d'Orbigny & Lafresnaye, 1837, Corrientes, Argentina.
Affiliations of genus uncertain; recent molecular-genetic analyses indicate that it does not belong with present family, and may be better placed with tanagers (Thraupidae). Two subspecies recognized.
Subspecies and Distribution.
S. s. similis d'Orbigny & Lafresnaye, 1837 – E Bolivia (Santa Cruz; one record Beni), C & E Brazil (N Mato Grosso and Bahia S to Mato Grosso do Sul and C & NE São Paulo), E Paraguay, NE Argentina (E Formosa and Misiones S to Santa Fe, Entre Ríos and NE Buenos Aires) and N Uruguay.
S. s. ochraceiventris Berlepsch, 1912 – SE Brazil (Paraná and SE São Paulo S to Rio Grande do Sul).



Descriptive notes. 20·5–21 cm; 36–54 g (Brazil). Nominate race has crown dull greyish with greenish tinge, whitish supercilium, grey lores and ear-coverts; upperparts greenish-grey, rump grey, rectrices dull dark grey; remiges dull greyish-black, broadly edged bright greenish-yellow (giving greenish-yellow appearance to closed wing); chin and throat white, malar stripe blackish; chest buffy with diffuse darker streaks, flanks buffy grey, belly more buff, vent brownish-buff; iris dark brown; bill grey; legs dull leaden grey. Sexes alike. Juvenile is like adult, but has black streaks on abdomen and breast. Race *ochraceiventris* differs from nominate in having underparts darker, more ochraceous, especially on abdomen and crissum. Voice. Song a short series of loud whistled notes, "chew-chew-cho-chewee". Also gives series of hurried twitterings.
Habitat. Woodland, including gallery forest and forest borders, and clearings. Lowlands to c. 1200 m.
Food and Feeding. In study of faecal samples in Mato Grosso do Sul (S Brazil), insects the predominant item, supplemented by fruit and berries. Will take swarming termites (Isoptera); also eats leaves of canema (*Solanum*) and seeds of *Pereskia* cactus, and seen to take sugary secretions of aphids (Aphidoidea) feeding on leguminous plant bracatinga (*Mimosa scabrella*). Forages mostly in pairs; sometimes joins mixed-species foraging flocks. Forages in several layers of forest, from medium levels of understorey up to subcanopy.
Breeding. In Brazil, eggs being incubated in early Nov and recently fledged young seen early Dec to early Jan in Rio Grande do Sul, and adult carrying food late Sept in Rio de Janeiro; nests in Oct–Dec in Uruguay. Nest a cup made from leaves and small twigs, lined with soft fine roots, external diameter 8 cm, cup 4·4 cm, placed 1–3 m up in tree. Clutch 2 eggs, rarely 3, pale blue or shiny blue-grey, marked at blunt end with black streaks or dots; no information on incubation and fledging periods, nor on parental involvement. Nests sometimes parasitized by Shiny Cowbird (*Molothrus bonariensis*).
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Fairly common in much of its range. Apparent expansion of range S in NE Argentina: first records in NE Buenos Aires during late 1980s, and species now appears to be established at various localities. Frequently taken as a cagebird.
Bibliography. Armani (1983), Bodrati & Sierra (2008), Faustino & Machado (2006), Fernández (1991), Ferreira & Glock (2004), Frisch & Frisch (1964), Hartert & Venturi (1909), Hellmayr (1908), Machado (1999), Mitchell (1957), van Perlo (2009), Piratelli & Pereira (2002), Ridgely & Tudor (1989, 2009), Rocha (2006), Sick (1993).

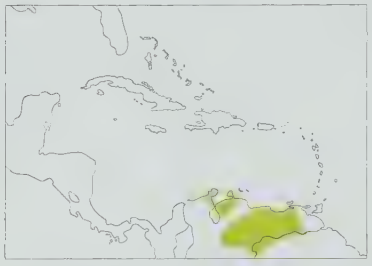
22. Greyish Saltator

Saltator coerulescens

French: Saltator gris **German**: Grausaltator **Spanish**: Pepitero Grisáceo
Other common names: Grey Saltator; Middle American Saltator ("*grandis* group")

Taxonomy. *Saltator coerulescens* Vieillot, 1817, Paraguay.
Affiliations of genus uncertain; recent molecular-genetic analyses indicate that it does not belong with present family, and may be better placed with tanagers (Thraupidae). Taxonomy of present species somewhat confused: Middle American races ("*grandis* group": *vigorsii*, *plumbiceps*, *grandis*, *yucatanensis*, *hesperis*, *brevicaudus*) possibly represent a separate species, and populations divided by Andes in N South America may perhaps be further differentiated. Further study warranted. Race *yucatanensis* intergrades with *grandis* in Belize. Proposed race *richardsoni* (described from Colima, in W Mexico) is a junior synonym of *plumbiceps*. Thirteen subspecies currently recognized.
Subspecies and Distribution.
S. c. vigorsii G. R. Gray, 1844 – W Mexico (S Sonora, Sinaloa, W Durango, Nayarit and N coastal Jalisco).
S. c. plumbiceps S. F. Baird, 1867 – W Mexico from C coastal Jalisco S to W Oaxaca.
S. c. grandis (W. Deppe, 1830) – E Mexico (from S Tamaulipas and E San Luis Potosí) S on Caribbean slope (except Yucatán) to N Guatemala, Belize, Honduras, Nicaragua, Costa Rica and W Panama.
S. c. yucatanensis Berlepsch, 1912 – Yucatán Peninsula (except extreme S Quintana Roo) and S Mexico (E Tabasco and NE Chiapas).
S. c. hesperis Griscom, 1930 – Pacific slope from S Mexico (E Oaxaca and Chiapas) and C & S Guatemala S to W Nicaragua.
S. c. brevicaudus van Rossem, 1931 – vicinity of Golfo de Nicoya, in Costa Rica.
S. c. plumbeus Bonaparte, 1853 – Caribbean coast of Colombia from R Sinú E to lower Magdalena Valley.
S. c. brewsteri Bangs & T. E. Penard, 1918 – NE Colombia (Norte de Santander and Arauca), Venezuela (except extreme SE) and Trinidad.
S. c. olivascens Cabanis, 1848 – SE Venezuela (Mt Roraima, in SE Bolívar), the Guianas and adjacent extreme N Brazil.
S. c. azarae d'Orbigny, 1839 – W Amazon Basin from E Colombia and W Brazil (E probably to R Negro region and, S of Amazon, to R Madeira) S to E Ecuador, E Peru and NE Bolivia (Beni).
S. c. mutus P. L. Sclater, 1856 – N Brazil from lower R Solimões E on both banks of R Amazon to Amapá and Mexiana I, S to N Maranhão.
S. c. superciliaris (Spix, 1825) – NE Brazil (S Piauí and N & W Bahia to N Minas Gerais).
S. c. coerulescens Vieillot, 1817 – E Bolivia (Santa Cruz and Tarija), SW Brazil (Mato Grosso), N Argentina (except Misiones; S to La Rioja, Córdoba, Santa Fe and N Buenos Aires), Paraguay and W Uruguay.

Descriptive notes. 20·5–21 cm; 49–67 g (Venezuela). Nominate race has crown greyish, supercilium from bill to above ear-coverts off-white, lores, face and ear-coverts mottled grey-brown; upperparts greyish, fine white edgings (in fresh plumage), rump dull grey-brown, rectrices dull blackish-grey; primaries and secondaries blackish-grey, paler edgings on outer webs; malar stripe blackish, throat off-white, chest and belly grey, lower belly and vent dull cinnamon; underwing-coverts dull cinnamon and blackish-grey; iris brown; bill blackish; legs leaden. Sexes alike. Juvenile is more olivaceous than adult, especially on head, with green edgings of flight-feathers, supercilium pale lemon-yellow, chest tinged with ochraceous yellow, vent pale cinnamon. Race *vigorsii* has head grey with short white supercilium, dark lores and blackish malar stripe; *grandis* resembles previous, but darker, head and upperparts dark olive-greyish, more extensive black on side of throat, only a narrow white chin stripe; *plumbiceps* is brownish, with black lores; *yucatanensis* is paler below than *grandis*, much lighter grey on breast, becoming buffy on flanks and undertail-coverts; *hesperis* is larger and darker than *grandis*, dark area on chest and breast more extensive and darker, white gular area smaller, upperparts slightly more slaty or bluish, supercilium narrower and shorter; *brevicaudus* is similar to previous, but smaller, with proportionately shorter tail, upperparts darker, less of an olivaceous tinge on rump and tail-coverts; *olivascens* is generally more olivaceous than adjacent races; *plumbeus* is generally similar to last, but upperparts and side of head decidedly paler olive-grey, white supercilium reduced or absent, malar stripe reduced, flanks and undertail-coverts paler buffy; *brewsteri* is like previous, but with more prominent white supercilium; *azarae* has upperparts leaden grey, breast clear grey; *mutus* resembles last, but much paler, with buffy (not ochraceous) undertail-coverts; *superciliaris* is similar to nominate, but smaller, less olivaceous on upperparts, side of head slate-grey (not olive-grey), throat pure white (not off-white), buff on abdomen paler and less extensive. Voice. Song varies much throughout range. For example, in Mexico, a rich, upslurred drawn-out "ch-kweet", often with varied, short, jerky preamble; in Costa Rica, described as a jerky series of mellow warbles, whistles and short sputtery notes, usually ending with upwardly or downwardly inflected whistle; in N Venezuela, a loud musical "wee chop cheeéeer", middle note dropping, while in WC Venezuela a halting or jerky series of emphatic phrases, somewhat musical; in Trinidad, verbalized as "pitch-oil, pitch-oil" (the local name for paraffin); in Peru, a variable series of rich, slurred whistles with rising or falling terminal note; in Brazil, consists of beautiful and very varied phrases of c. 4–8 strong clear notes. Calls are single-syllable "chin", squeaky "tseet" and similar.
Habitat. Occupies forest edge and second growth, including, in various parts of range, dry scrub, humid forest borders and gallery forest, but not usually unbroken forest interior. From sea-level up to 1500 m in Mexico, and up to 1850 m in Costa Rica; in South America up to 1500 m, but in many areas lower.
Food and Feeding. Apparently varied in different parts of range. In one lowland study in Venezuela, diet predominantly vegetable, including fruits and flower buds and leaves (captive birds fed exclusively on leaves lost weight); in lowland study in Argentina species was more omnivorous, taking both seeds, especially those of *Solanum amygdalifolium*, and insects, including leaf-cutter ants (*Acromyrmex*), though beetles (Coleoptera) and other insects featured prominently. In Venezuela largely vegetarian, but more insects fed to young. In dry tropical forest in Mexico, proportion of diet derived from animal sources increases in rainy season. Will come to gardens to eat cultivated beans and tomatoes. Feeds singly or in small groups; sometimes in mixed-species foraging flocks. Forages mostly in upper levels of vegetation.
Breeding. Season Apr–Jul in Costa Rica, May–Oct in Venezuela, Mar–Oct (mainly May and Jun) in Trinidad, Apr–Jun in Colombia, and late Oct to early Jan in Argentina. Possibly sometimes co-operative breeder, with helpers. Nest a bulky cup with twig foundation, middle layer of small leaves and thick lining of fine fibres and rootlets, external diameter 11–16 cm, cup 8–9 cm across and 3–5 cm deep, usually located c. 1·7–4 m up in large bush or shrubbery. Clutch usually 2 eggs, rarely 3, blue-green with black spots and scrawls, especially at blunt end; incubation period 13–14 days, in Honduras reported as 15 days; nestling period 18–19 days (Argentina). Nest parasitism by Shiny Cowbird (*Molothrus bonariensis*) recorded in Argentina.
Movements. Apparently sedentary; race *brewsteri* has occurred as vagrant in Tobago.
Status and Conservation. Not globally threatened. Common in much of its range. W Mexican race *vigorsii* has recently extended range N to colonize S Sonora. Adapts well to man-modified habitats. In Argentina, may cause damage to leguminous crops.
Bibliography. Beltzer (1988a), Beltzer *et al.* (2004), Bosque *et al.* (1999), Chatellenaz (2008), Dinelli (1924), Echeverry-Galvis & Córdoba-Córdoba (2006), ffrench (1973, 1984), Hellmayr (1929), Herklots (1969), Herrera *et al.* (2006), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995), Junge & Mees (1958), Ludwig (1998), Monroe (1968), de la Peña (2005), van Perlo (2009), Retter (2010), Ridgely & Tudor (1989, 2009), Rodríguez-Ferraro *et al.* (2007), Short (1975), Skutch (1945), Stiles & Skutch (1989).



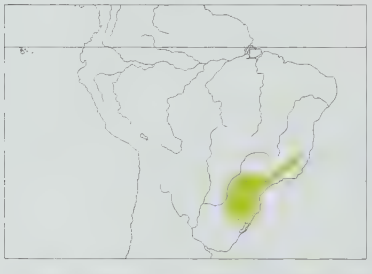
23. Orinocan Saltator

Saltator orenocensis

French: Saltator de l'Orénoque **German**: Zimtflankensaltator **Spanish**: Pepitero del Orinoco

On following pages: 24. Thick-billed Saltator (*Saltator maxillosus*); 25. Black-cowled Saltator (*Saltator nigriceps*); 26. Golden-billed Saltator (*Saltator aurantiirostris*); 27. Masked Saltator (*Saltator cinctus*); 28. Black-throated Saltator (*Saltator atricollis*); 29. Rufous-bellied Saltator (*Saltator rufiventris*); 30. Lesser Antillean Saltator (*Saltator albicollis*); 31. Streaked Saltator (*Saltator striatipectus*).

Taxonomy. *Saltator orenocensis* Lafresnaye, 1846, mouth of the Orinoco, Venezuela.
Affiliations of genus uncertain; recent molecular-genetic analyses indicate that it does not belong with present family, and may be better placed with tanagers (Thraupidae). Two subspecies recognized.
Subspecies and Distribution.
S. o. rufescens Todd, 1912 – NE Colombia (Guajira Peninsula E from Santa Marta) and W Venezuela (N & SE Zulia E to N Lara and C Falcón).
S. o. orenocensis Lafresnaye, 1846 – Venezuela E of Andes from Cojedes and W Apure E to W Sucre and S Monagas, to S bank of R Orinoco in N Bolívar and S Delta Amacuro) and NE Colombia (Arauca, probably also N Vichada).



Descriptive notes. 18·5–19 cm; average 33·7 g (six birds from Venezuela). Nominate has lores, face, ear-coverts and malar region black, long white supercilium extending past ear-coverts; crown and upperparts slate-grey, feathers of upperwing blackish, edged slate-grey, broadest on coverts and tertials; rectrices dull black, primaries brownish with narrow pale edgings on outer webs; small area at base of lower mandible, chin, throat and breast white, becoming strongly buff on belly, especially at side; vent and undertail-coverts buffy-brown; iris brown; upper mandible black, lower mandible blackish with pale leaden base; legs blackish. Sexes alike. Juvenile apparently undescribed. Race *rufescens* is larger than nominate, with bill stouter, forehead and side of crown (bordering broad white supercilia) black, underparts strongly shaded with buffy-clay colour. Voice. Song a loud, rollicking series of notes, often given by more than one bird, perhaps antiphonally, "cheeyir-cheeyir-cheeyir", ending in musical jumble of notes; song reportedly varies within species' range, but no published details available.
Habitat. Inhabits dry deciduous woodland and brush, including well-vegetated suburban areas, mesic vegetation along dry washes in arid areas; also borders of gallery forest. Occurs from sea-level up to 600 m.
Food and Feeding. Diet predominantly vegetable, with some insects. Recorded items include flowers, fruits (in the wild, fruits of *Annona jahni* and *Momordica charantia*; in captivity, readily takes papaya and guava), and seeds; also a significant proportion of leaves, although captive individuals offered a choice prefer fruit. Forages in twos and threes, generally not joining mixed-species flocks. Searches at high levels in trees, occasionally a little lower.
Breeding. Few data. In Venezuela, single nests found in May and mid-Jun in Orinoco region and birds in breeding condition in May in Guárico. Nest described as a loose grassy cup, placed 2–5 m up, one in cane and the other in low bush. Clutch 2 eggs, greenish-blue with black lines and spots around blunt end. No other information.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Fairly common in suitable habitat in parts of range. Reports of presence in Trinidad erroneous.
Bibliography. Armani (1983), Berlepsch & Hartert (1902), Bosque *et al.* (1999), Cherrie (1916), Hilty (2003), Hilty & Brown (1986), Ridgely & Tudor (1989, 2009), Schönwetter & Meise (1981), Todd (1912).

24. Thick-billed Saltator

Saltator maxillosus

French: Saltator à bec épais **German**: Dickschnabelsaltator **Spanish**: Pepitero Picudo

Taxonomy. *Saltator maxillosus* Cabanis, 1851, Montevideo; error = southern Brazil.
Affiliations of genus uncertain; recent molecular-genetic analyses indicate that it does not belong with present family, and may be better placed with tanagers (Thraupidae). Present species closely allied to *S. nigriceps* and *S. aurantiirostris*; interbreeding with latter has been reported, but recent studies state that there is little or no interbreeding. Monotypic.
Distribution. SE Brazil (extreme SE Bahia and extreme E Minas Gerais S to Paraná and Rio Grande do Sul) and extreme NE Argentina (Misiones).

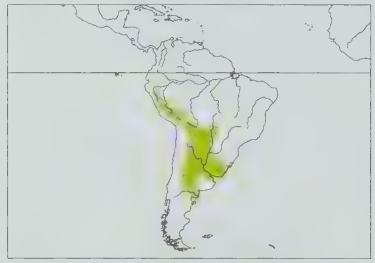
Descriptive notes. 21 cm; 48–54 g (four birds Brazil). Male has lores, area around eye and face dark brownish-grey, long white supercilium; crown and upperparts dark brownish-grey, upperwing-coverts with mostly concealed dusky areas; primaries blackish-grey with narrow pale grey edgings on outer webs; rectrices dull blackish-grey; chin and throat off-white with variable orange-buff to clay-coloured tinge, diffuse blackish malar stripe; underparts buffy grey, vent and undertail-coverts clay-coloured; iris dark brown; bill heavy, dark, some orange at base; legs greyish. Female is olive above, including ear-coverts, with white supercilium, blackish malar stripe, throat buffy; otherwise much as for male but with mostly blackish bill. Juvenile has green upperparts, all-dark bill. Voice. Song a simple series of 4 loud notes, the third higher in pitch, "teeu-teeu-tew-tcheeuw"; call a high, clear "wicwic".
Habitat. Mostly canopy of montane humid forest and woodland borders; to 2200 m, rarely down to sea-level.
Food and Feeding. Unusually for a passerine, seems to be an obligate folivore, at least during dry season when fruit less available. Diet, based on dry-season observations, includes leaves of several families of trees (Melastomataceae, Solanaceae, Rubiaceae and Asteraceae, among others), as well as fruits of various species. No observations during breeding season, when other members of genus tend to eat more animal matter. Usually in pairs; often joins mixed-species flocks. Forages at all levels, mostly at higher ones.
Breeding. Nest a cup made from roots, dry leaves and other vegetation, lined with fine fibres, rootlets and similar fine material, situated at low to medium height in tree or bush. Clutch 2–3 eggs, pale blue with brown or black markings. No other information.
Movements. Probably largely sedentary; tends to occur more frequently at lower altitudes during austral winter.
Status and Conservation. Not globally threatened. Uncommon. Formerly occurred also in E Paraguay (Alto Paraná), but no records since early decades of 20th century. Much of this species' habitat has been destroyed during last century. Occurs in some protected areas, including Itatiaia National Park, in Brazil.
Bibliography. Armani (1983), Honkala & Niiranen (2010), Munson & Robinson (1992), van Perlo (2009), Ridgely & Tudor (1989, 2009), da Silva (1990), Sick (1993).

25. Black-cowled Saltator

Saltator nigriceps

French: Saltator à capuchon **German**: Schwarzgesichtsaltator **Spanish**: Pepitero Capuchinegro

Taxonomy. *Pitylus nigriceps* Chapman, 1914, Loja, 7000 feet [c. 2130 m], Ecuador.
Affiliations of genus uncertain; recent molecular-genetic analyses indicate that it does not belong with present family, and may be better placed with tanagers (Thraupidae). Present species sometimes treated as conspecific with *S. aurantiirostris*, but appears to differ vocally; closely allied also with *S.maxillosus*. Monotypic.
Distribution. S Ecuador (El Oro and Loja) and NW Peru (Piura, extreme E Lambayeque and Cajamarca).



Descriptive notes. 22 cm. Has head to upper chest black, occasionally with a few white feathers on chin and behind eye; upperparts, including wing and tail, are dark bluish-grey, greyish-black on concealed parts of remiges and rectrices, outer rectrices tipped white; underparts clear grey, becoming buff on lower belly and thigh, and cinnamon-buff on undertail-coverts; iris brown; bill orange or salmon-red; legs grey or horn-blue. Sexes alike. Juvenile undescribed. Voice. Song is simple and short, comprising a ringing explosive "keert, swee-it"; call is a metallic ringing "chee" and a high "tsee".
Habitat. Humid montane forest and forest edge, and regenerating scrubland. Mostly 1700–2900 m, occasionally down to 1550 m, in Ecuador; 1200–2500 m in Peru.
Food and Feeding. No published data on diet. Usually in pairs; sometimes joins mixed-species foraging flocks. Largely arboreal.
Breeding. No information.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tumbesian Region EBA. Rather uncommon to locally fairly common. Has been proposed for listing as Near-threatened, but in view of its ability to adapt to degraded habitat this is probably not justified.
Bibliography. Best *et al.* (1993), Ridgely & Greenfield (2001a), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007).

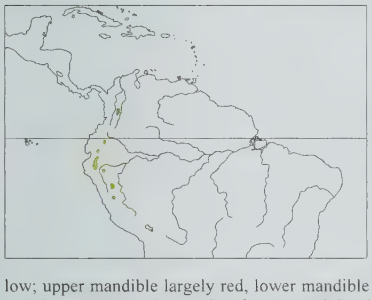
26. Golden-billed Saltator

Saltator aurantiirostris

French: Saltator à bec orange **German**: Goldschnabelsaltator **Spanish**: Pepitero Piquigualdo

Taxonomy. *Saltator aurantiirostris* Vieillot, 1817, "Paraguay"; probably Corrientes, Argentina.
Affiliations of genus uncertain; recent molecular-genetic analyses indicate that it does not belong with present family, and may be better placed with tanagers (Thraupidae). Present species sometimes treated as conspecific with *S. nigriceps*, but appears to differ vocally. Also closely allied to *S. maxillosus*; interbreeding with latter has been reported, but recent studies state that there is little or no interbreeding. Race *parkesi* intergrades with nominate in Argentina. Six subspecies recognized.
Subspecies and Distribution.
S. a. iteratus Chapman, 1927 – N Peru (temperate zones of Cajamarca, Amazones, Libertad and Ancash).
S. a. albociliaris (R. A. Philippi [Krumwiede] & Landbeck, 1861) – C & S Peru (subtropical and temperate zones from Ancash and Huánuco S to Puno and Tacna) and extreme N Chile (Arica).
S. a. hellmayri J. Bond & Meyer de Schauensee, 1939 – Bolivia from La Paz and Cochabamba S to SE Potosí and N Tarija.
S. a. aurantiirostris Vieillot, 1817 – Bolivia (S Tarija), N Argentina (S to Catamarca, Córdoba and Buenos Aires), E Paraguay and S Brazil (S Mato Grosso and N Rio Grande do Sul).
S. a. parkesi da Silva, 1990 – E Argentina (Entre Ríos), extreme SE Brazil (S Rio Grande do Sul) and Uruguay.
S. a. nasica Wetmore & J. L. Peters, 1922 – CW Argentina (La Rioja, San Juan, Mendoza and W La Pampa).

Descriptive notes. 19–20·5 cm; male 33·1–44·8 g, female 38–54·3 g (Bolivia). Male nominate race has forehead blackish, becoming grey on crown and nape; chin and throat white, lores, face, ear-coverts and border of throat (upper chest) black; white supercilium behind eye extending into white crescent behind ear-coverts; upperparts, including upperwing and tail, grey, outer rectrices without white tips or outermost with only very narrow white edging; underparts below black breastband clear grey, becoming buffy on upper abdomen and warmer buff on vent; iris medium to dark brown; bill orange; legs dark brown or leaden grey. Female has bill suffused with dusky, black of head and face replaced by dull brownish-black, supercilium and chin whitish yellow-buff, little or no pectoral band. Juvenile resembles female, but head plumage much as for male, lacks pectoral band, bill dusky with dull yellowish tip on both mandibles. Races differ mainly in plumage details, Andean races with less distinction between the sexes: *iteratus* has pectoral band well developed, gular area buffy white, outer two rectrices with narrower white tips, bill small; *albociliaris* is similar to previous, but gular white restricted to a central line down chin and throat; *hellmayri* is like nominate, but darker grey with very faint olive cast above, crown feathers tipped black when fresh, supercilium pure white, ear-coverts of female darker, breast and belly paler and greyer, outer rectrices with white tips; *parkesi* is similar to nominate, but supercilium warm buff, not white; *nasica* has rectrices without white tips, bill larger than



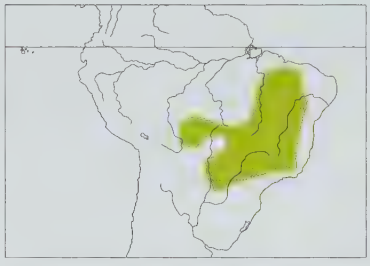
in nominate. Voice. Song a loud, explosive series of musical whistled phrases, e.g. "twi-chéw tew-swéé?", final syllable emphasized. Calls include metallic "chip" or "zak"; alarm "rrr".
Habitat. Montane scrub, field edges, gardens, *chaco* woodland etc. Down almost to sea-level in S Brazil, Argentina and Uruguay; Andean populations mostly 1500–3800 m.
Food and Feeding. Only quantified study was in lowland habitat in Santa Fe, in Argentina: diet included large numbers of seeds, especially of *Solanum amygdalifolium*, along with various insects, e.g. leaf-cutter ants (*Acromyrmex*), beetles (Coleoptera), true bugs (Hemiptera), flies (Diptera). Usually in pairs.
Breeding. Season Nov–Jan, rarely Oct, in Argentina and Oct–Jan in Uruguay; fledglings in Jun in Peru and Feb–Mar in Bolivia. Almost all data from Argentine studies. Nest a cup of straw, stems and lichens, lined with rootlets and leaves, external diameter 10–15 cm, cup diameter 7–9 cm, overall depth 7–12 cm, sited 1·2–3·7 cm up in shrub or bush, commonly in tala (*Celtis spinosa*), chañar (*Geoffroea decorticans*) or similar, often half-hidden by creepers. Clutch 2–3 eggs, blue-green with black spots, streaks and lines, especially around blunt end, where sometimes forming ring; incubation period 14 days; nestling period 17–18 days.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Quite common in suitable habitat over much of its range. In agricultural areas, may sometimes cause damage to pulses at the budding stage.
Bibliography. Armani (1983), Beltzer (1988a), Beltzer *et al.* (1999), Bond & Meyer de Schauensee (1939, 1942), Carriker (1933), Chapman (1927b), Dinelli (1924), Fjeldså & Krabbe (1990), Grilli *et al.* (2006), Mezquida (2003), de la Peña (1987, 1996a, 2005), Ridgely & Tudor (1989, 2009), Rocha (2006), Schulenberg *et al.* (2007), da Silva (1990).

27. **Masked Saltator**

Saltator cinctus

French: Saltator masqué **German**: Maskensaltator **Spanish**: Pepitero Enmascarado

Taxonomy. *Saltator cinctus* J. T. Zimmer, 1943, Cutucú, 2000 m, near Macas, Zamora, Ecuador.
Affiliations of genus uncertain; recent molecular-genetic analyses indicate that it does not belong with present family, and may be better placed with tanagers (Thraupidae). Colombian populations of present species seem to exhibit constant differences in plumage and bill colour from those in rest of range, and may represent a separate taxon; further study required. Currently treated as monotypic.
Distribution. Several, apparently disjunct populations: in Colombia on both slopes of C Andes in Caldas, Risaralda, Quindío and Tolima, in Valle de Cauca, Parques Regionales Ucumán and La Vereda Canoas and Reserve Patasola; in Ecuador at scattered locations in W Napo, W Morona-Santiago, Zamora-Chinchipe and S Loja; and in Peru in E Piura, Cajamarca, San Martín and Huánuco.



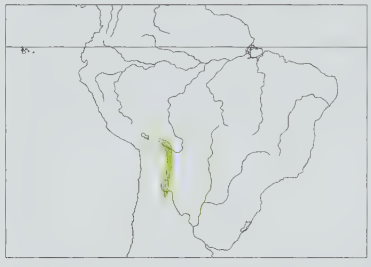
Descriptive notes. 21·5 cm; 43–53 g (Ecuador and Peru). Has crown and upperparts slate-grey, flight-feathers and upperwing-coverts black, broadly edged with clear dark grey, rectrices black, outer four with broad white tips, inner two narrowly tipped white; lores back to ear-coverts and down to chin and throat black (in Colombia, narrow pale streak separating black mask from the grey of rear head); upper chest white, broad black band across chest, rest of underparts white (in Colombia belly creamy white, not pure white), flanks grey, vent broadly barred black and white; iris orange or golden, inner ring yellow; upper mandible largely red, lower mandible black mixed with red (in Colombia bill wholly red); legs slate-grey. Sexes alike, female possibly with red of upper mandible more extensive. Juvenile is duller than adult, black mask less extensive, bill pale yellow. Voice. Song, in Ecuador, a rich, mellow whistled phrase, "tu-chew-chew-chew-wuri?". Calls "tzip" or "tseeyk", a soft "tiu-tiu", "chu" and similar.
Habitat. Subtropical steep montane forest. In Colombia, mixed woodland of average height of 15 m with higher trees to 20 m, including Melastomaceae, Cunoniaceae and Lamiaceae, with ferns and palms; farther S, frequently in *Podocarpus oleifolius*. Despite earlier reports, probably not strongly associated with *Chusquea* bamboo, although recorded in such habitat. From at least 2500 m to 3080 m in Colombia; 2000–2700 m In Ecuador and 1700–3000 m in Peru.
Food and Feeding. Recorded items include various fruits, especially *Podocarpus*, also arillate seeds of *Clusia* and other trees and vines; once seen to eat young leaves. Associates to variable degree with other species, including conebills and various other tanagers (Thraupidae) and woodcreepers (Dendrocolaptidae). Forages mostly in canopy.
Breeding. Apparent breeding behaviour and juvenile being attended by an adult at end Apr in Colombia. Observations of agitated birds suggest that nest probably situated fairly low down in dense vegetation. Only one egg described (laid in a bag by captured female on 25th Feb in Risaralda, at 2680 m in Colombia), clear blue, marked at blunt end with very dark brown blotches. No other information.
Movements. Resident; appears to be somewhat nomadic, possibly in response to variation in abundance of fruiting trees (sometimes absent from locations where previously observed).
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Generally rare and local; apparently nowhere common. Possibly declining as a result of habitat loss. Seems to be strongly associated with *Podocarpus*, a species under great pressure, even in some officially protected areas. Present in a number of protected areas in all three countries of its range.
Bibliography. Anon. (2010b), Butchart & Stattersfield (2004), Collar *et al.* (1994), Echeverry-Galvis & Córdoba-Córdoba (2006), O'Neill & Schulenberg (1979), Renjifo (1991, 2002), Ridgely & Greenfield (2001a), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Stattersfield & Capper (2000), Tobias & Williams (1996), Zimmer (1943d).

28. **Black-throated Saltator**

Saltator atricollis

French: Saltator à gorge noire **German**: Schwarzhalssaltator **Spanish**: Pepitero Gorjinegro

Taxonomy. *Saltator atricollis* Vieillot, 1817, Paraguay.
Affiliations of genus uncertain; recent molecular-genetic analyses indicate that it does not belong with present family, and may be better placed with tanagers (Thraupidae). This species has been thought to be not closely related to other members of genus, but closer to monotypic emberizid genus *Saltatricula*; recent molecular-genetic studies, however, indicate that it does belong in present genus, and that *Saltatricula* perhaps better moved to present family. Monotypic.
Distribution. E & C Brazil (from N Ceará and Maranhão, also recently Pernambuco, S in interior to Mato Grosso, N São Paulo and S Minas Gerais), E Bolivia (NE Beni and E Santa Cruz) and NE Paraguay.



Descriptive notes. 20–20·5 cm; one male 53·8 g. Forehead is dark brown, crown and upperparts, including upperwing-coverts and remiges, dull dark brown with lighter brown feather edges; tail dark brown with diffuse darker transverse bars; face, chin and throat black, merging into brownish-grey on posterior ear-coverts; chest pale buffy grey, becoming warmer buff on belly, flanks and vent; iris chocolate-brown; bill orange, blackish culmen; legs light brown. Sexes alike. Juvenile has buff edgings on black throat feathers, dark bill. Voice. Song a fast and musical jumbled warbling, e.g. "weet-jewir-p-weetjeweer", lasting c. 3 three seconds, unlike that of any other member of genus; several individuals may sing together antiphonally. Call a high "wheek-wheek" or "bits", like sound of pebbles clicking together; alarm call at nest a loud penetrating "squeeeuw".
Habitat. Dry *caatinga* and *cerrado* scrub, mostly at 500–1300 m, locally to 1800 m in E Brazil.
Food and Feeding. Diet in Minas Gerais (Brazil) mostly seeds and flower buds, followed by fruit and small numbers of invertebrates. Occurs in mixed-species foraging flocks, typically being found alone only when breeding; often acts as a nucleus to other flocking species and frequently performs sentry duty, sitting on exposed perch and giving universally recognized alarm call on approach of predator. Forages frequently on ground.
Breeding. Few data available, all from Minas Gerais (Brazil). Birds carrying food to young in Mar–Apr, nest with well-feathered young on 17th Mar and another with two well-feathered young in late Oct, and adult carrying nesting material on 10th Oct; spread of dates suggests that species possibly at least double-brooded. Evidence of additional birds other than parents helping at some nests. One nest a cup of coarse grasses and twigs, external diameter 15·5 × 13·5 cm, cup diameter 8·8 cm, situated 0·9 m up in bush; second nest, at 1250 m, was a grass cup c. 9 cm in internal diameter and 18 cm in external diameter, built on ground into side of tussock of coarse grass, some very small bushes giving sparse concealment from above. Clutch 2 eggs, blue or greenish-white, marked with dull brown or black. No other information.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Quite common in parts of its range. First recorded in Beni, in NE Bolivia, in 2004, since when there have been several further observations. This species' habitat is under threat in many parts of its range; some areas of habitat protected by national parks.
Bibliography. Armani (1983), Buzzetti & Silva (2005), Gomes de Almeida (2009), Herrera & Vidoz (2009), Levy (2009), Parker & Rocha (1991), van Perlo (2009), Ragusa-Netto (2001, 2002b), Ridgely & Tudor (1989, 2009), Sick (1993), Telino *et al.* (2008).

29. **Rufous-bellied Saltator**

Saltator rufiventris

French: Saltator à ventre roux **German**: Rotbauchsaltator **Spanish**: Pepitero Colorado

Taxonomy. *Saltator rufiventris* d'Orbigny and Lafresnaye, 1837, Sicasica, Bolivia.
Affiliations of genus uncertain; recent molecular-genetic analyses indicate that it does not belong with present family, and may be better placed with tanagers (Thraupidae). Recent molecular-genetic analyses indicate that this species is closer to thraupid genera *Delothraupis* and *Dubusia* and may merit placement in a separate genus, for which a new name would be needed; further study required. Monotypic.
Distribution. C Andes from C Bolivia (La Paz, Cochabamba and Chuquisaca) S, probably discontinuously, to NW Argentina (Jujuy and Salta).

Descriptive notes. 22 cm; male 68–80·5 g, female 67·8–79·8 g. Male has top of head and upperparts, including upperwing-coverts, uniformly blue-grey, rectrices greyish-black with bluish tinge on outer webs; long, narrow white supercilium extending back to side of nape; face down to chin and chest blue-grey, contrasting sharply with bright reddish-buff lower chest, abdomen and vent; iris red; bill dusky brown, cream-coloured base of lower mandible; legs brownish-horn. Female is similar to male, but, generally less bluish on upperparts, more faded below, iris amber. Juvenile is like adult, but bill paler. Voice. Song a short, fast subdued "cheree-cheree-cheree-chew" on even pitch; calls a soft "phueet-phueet", an unmusical, irregular "rrhe-rrhe", and a louder "whueet-whueet".
Habitat. Usually associated with *Polylepis* woodland; also occurs in shrubby thickets and agricultural fields. In Argentina, usually found in dry shrubbery on high slopes or in *quebradas* (ravines). Mostly in rather dry regions, but in E Bolivia in humid montane forest. Mostly 2500–3500 m, sometimes to 4000 m.
Food and Feeding. Few published data. Seen to eat fruits of *Berberis* and *Heteromelas* and berries of mistletoe (of genus *Tristerix*); said also to eat seeds and insects; individual in Argentina fed mostly on *Brachyotum* berries, also on young leaves of introduced willow (*Salix*), and took grass shoots from ground. Stomach contents in May and Aug were vegetable matter, including plant fibres and fruit seeds. Mistletoe berries may be important food source; whereas mistletoe berries in *Polylepis* occur throughout year, those growing on alder (*Alnus*) are more seasonal. Mostly in loose pairs; associates with *S. aurantiirostris* and White-tipped Plantcutters (*Phytotoma rutila*). Forages mainly in trees and other vegetation, sometimes on ground; has been seen to forage on ground in ploughed field.
Breeding. Birds in juvenile plumage in Aug and Sept, pair in Apr and female on 9th May in intermediate breeding condition, and others in May and Aug with undeveloped gonads; season likely in Dec and Jan. Nest a cup made from roots, dry leaves and similar material, lined with vegetable fibres and fine grasses, situated at medium height in scrub, thickly leaved bush or tree. Clutch 3 eggs, bluish with dull brown or black markings. No other information.
Movements. Apparently resident.

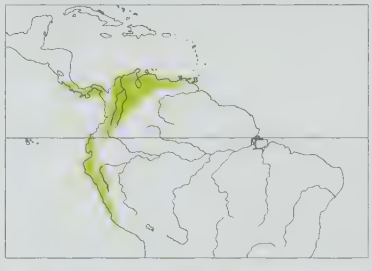
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in High Andes of Bolivia and Argentina EBA. Locally common to uncommon in Bolivia; current status in Argentina uncertain, seems generally rare or uncommon, and has disappeared or declined greatly in some areas where previously abundant. In Bolivia, common at some sites in Cochabamba and in one area in La Paz, but very local outside Cochabamba; several new sites discovered as a result of increased fieldwork; total Bolivian population thought to exceed 10,000 individuals. Largely, but not exclusively, associated with *Polylepis* forest, a habitat under much pressure for its timber. Greatest threats appear to be uncontrolled burning of woodland and removal of *Polylepis*; if, owing to seasonality of mistletoe berries, *Polylepis* is essential at certain times of year, the situation could be more serious than it currently appears. Occurs in some protected areas, e.g. Tunari National Park, in Bolivia, and Calilegua National Park, in Argentina.
Bibliography. Anon. (2010b), Armani (1983), Butchart & Stattersfield (2004), Collar *et al.* (1992), Fjeldsá & Krabbe (1990), Mazar Barnett, Clark *et al.* (1998), Pearman (1997), Remsen *et al.* (1988), Ridgely & Tudor (1989, 2009), Stattersfield & Capper (2000).

30. **Lesser Antillean Saltator**

Saltator albicollis

French: Saltator gros-bec **German**: Antillensaltator **Spanish**: Pepitero Antillano

Taxonomy. *Saltator albicollis* Vieillot, 1817, Cayenne; error = Martinique.
Affiliations of genus uncertain; recent molecular-genetic analyses indicate that it does not belong with present family, and may be better placed with tanagers (Thraupidae). Present species formerly treated as conspecific with *S. striatipectus*, but analyses of mitochondrial DNA clearly indicate that genetic differentiation sufficient to support treatment as two separate species. Race *guadelupensis* not always distinguishable from nominate. Two subspecies tentatively recognized.
Subspecies and Distribution.
S. a. guadelupensis Lafresnaye, 1844 – Guadeloupe and Dominica, in NC Lesser Antilles.
S. a. albicollis Vieillot, 1817 – Martinique and St Lucia, in C Lesser Antilles.



Descriptive notes. 22 cm; 39·8–51·6 g (St Lucia). Nominate race has crown and neck to back, including upperwing-coverts, deep olive-green, lower back and rump greyish; flight-feathers blackish-grey with olive-green edgings on outer webs, olive-green on outer webs of tertials (giving olive-green appearance to closed wing), carpal region yellow-green; rectrices uniformly dull grey-brown; narrow greenish-white supercilium; lores, face and ear-coverts mottled greyish; throat pale greenish-white, flanked by diffuse darker submoustachial streak; chest dull olive with obscure darker streaking, flanks greyish, vent buffy; underwing-coverts pale buff; iris dark brown; bill blackish, yellow tip and gape; legs brown. Sexes alike. Juvenile resembles adult, but facial pattern duller and streaking below more diffuse. Race *guadelupensis* usually has darker, more tawny or yellowish, underparts than nominate, but some apparently inseparable from latter. Voice. Song a series of rather loud, harsh, rising and falling notes.
Habitat. Wide variety of habitats, e.g. mangroves, forests of several types, including dry, marshy and humid; most common in dry forest and copses. From sea-level to 500 m.
Food and Feeding. Food vegetable matter, including fruits, buds, some flowers and petals; also some insects. Nestling diet fruits, petals, stamens of plants such as *Calliandra purpurea*, seeds, rarely insects. Forages generally in pairs.
Breeding. Season Feb–Aug, peak in May–Jun; height of song period Feb–Jun, some song persisting from Sept onwards. Nest a deep cup made from twigs and leaves, external diameter c. 18·5 cm, cup diameter c. 9 cm and depth c. 5 cm, located c. 2·5–4·5 m up in bush or tree. Clutch 2–3 eggs, light greenish-blue with black lines concentrated around blunt end; no information on incubation and nestling periods; chicks fed by both parents; fledglings attended by both parents for some time after leaving nest.
Movements. Sedentary. Presumed vagrant (assuming no captive origin) recorded on Nevis, c. 120 km over water from nearest breeding range (Guadeloupe).
Status and Conservation. Not globally threatened. Fairly common to common in suitable habitat. Small global range, restricted to four islands in E Caribbean region.
Bibliography. Bénito-Espinal & Hautcastel (2003, 2007), Bond (1985), Evans (1990), Raffaele *et al.* (1998), Seutin *et al.* (1993).

31. **Streaked Saltator**

Saltator striatipectus

French: Saltator strié **German**: Strichelsaltator **Spanish**: Pepitero Listado

Taxonomy. *Saltator striatipictus* (sic) Lafresnaye, 1847, Cali, Valle de Cauca, Colombia.
Affiliations of genus uncertain; recent molecular-genetic analyses indicate that it does not belong with present family, and may be better placed with tanagers (Thraupidae). Present species formerly treated as conspecific with *S. albicollis*, but analyses of mitochondrial DNA clearly indicate that genetic differentiation sufficient to support treatment as two separate species. In addition, has been suggested that races may involve more than one species; further study needed. Also, in SW Ecuador, adults on Puná I, which lies within range of race *flavidicollis*, are streaked below (unlike *flavidicollis*) and greyish above (like nominate); may be worthy of taxonomic differentiation. Ten subspecies currently recognized.
Subspecies and Distribution.
S. s. furax Bangs & T. E. Penard, 1919 – SW Costa Rica and W Panama (W Chiriquí).
S. s. isthmicus P. L. Sclater, 1861 – mainland Panama, (except extreme W & E).
S. s. scotinus Wetmore, 1957 – Coiba I and Coibita I, off S Veraguas (SW Panama).
S. s. melicus Wetmore, 1952 – Taboga I, off S Panamá (C Panama).
S. s. speratus Bangs & T. E. Penard, 1919 – Pearl Is (San Miguel, Saboga and Viveros), off S Panama.
S. s. striatipectus Lafresnaye, 1847 – E Panama (Darién), and W Colombia S, W of Andes, to N Ecuador.
S. s. perstriatus Parkes, 1959 – NE Colombia (Magdalena, NE Bolívar and Norte de Santander) E through mountains of N Venezuela to Sucre and Monagas; Trinidad.
S. s. flavidicollis P. L. Sclater, 1860 – lowland W Ecuador and NW Peru.
S. s. immaculatus Berlepsch & Stolzmann, 1892 – arid coast of W Peru (Lambayeque S to Ica).
S. s. peruvianus Cory, 1916 – Marañón drainage of SE Ecuador (Zamora-Chinchipe) and NE Peru (upper Marañón Valley in Cajamarca and La Libertad).

Descriptive notes. 19–20·5 cm; 30–44 g (Trinidad), one bird from Colombia 41·5 g, one from Peru 36·5 g. Nominate race has crown greyish-green, becoming more green on back and upperwing-coverts; rump greyish; flight-feathers blackish, broad olive-green edgings on outer webs, tertials with entire outer web greenish (giving olive-green appearance to closed wing), rectrices dull grey-brown; narrow supercilium in front of eye buffy white, area above eye whitish, lores and ear-coverts brownish-grey, dusky malar line slightly highlighted by some narrow off-white feathers separating it from plain lower face; throat whitish, chest off-white with diffuse darker streaks, belly buff-white with diffuse grey-black streaks at side, vent and undertail-coverts buffy-white; iris brown; bill blackish with yellow gape and sometimes yellow tip; legs grey-black to black. Sexes alike. Juvenile is similar to adult, but colour of back duller and less green. Race *furax* is smaller and much darker below than nominate, streaking below wider, heavier and more extensive; *isthmicus* is smaller than nominate, underparts more greenish or yellowish, stripes rather heavier and more olive-green, less greyish; *scotinus* is darkest race, closest to previous, but darker, greyer green above, with side of head and streaks below darker, edge of wing brighter yellow, undertail-coverts deeper buff; *melicus* is generally similar to *isthmicus*, but bill larger and heavier, side of head greyer, lateral throat streak greyer, flanks darker, and uppertail-coverts and uppertail darker grey; *speratus* is smaller than nominate, more yellowish or greenish below, less heavily streaked than *isthmicus*; *perstriatus* is similar to nominate, but clear green, less greyish, above, more heavily streaked below, streaks extending onto abdomen, and bill almost always tipped yellow; *flavidicollis* has supercilium longer and more prominent than nominate, upperparts olive, underparts whitish, sometimes tinged yellow, and streaks largely lacking (juvenile streaked), on Puná I (SW Ecuador) adult grey above and streaked below; *immaculatus* has supercilium inconspicuous, head greyish, upperparts mainly dull greyish, and chest pale greyish with little streaking, whiter throat and belly; *peruvianus* is very olive on upperparts, streaking on underparts heavy, supercilium inconspicuous, more black on bill. Voice. Song, mostly from cover 2–3 m up, sometimes (especially at dusk) in flight, a series of 4–5 whistled syllables, each lasting c. 0·2 seconds, with slightly shorter gap between notes, followed by two falling, harsher notes, "chu-chu-chu-chu-ch'ree-rerr-chip"; at dawn, often only harsher notes in a series. Flight contact call "qua-qua-qua"; also a loud "quik".
Habitat. Second growth, regenerating farmland, timbered gardens, forest edge; not in interior forest. In Venezuela not found in arid regions, but in Ecuador and Peru occurs in dry forest. Generally sea-level to 1500 m, more rarely to 2500 m.
Food and Feeding. Diet mixed animal and vegetable: prey items include ants (Formicidae), beetles (Coleoptera); vegetable items seeds, flowers, buds, various fruits, including (in Venezuela) fruits of columnar cacti. In Costa Rica, young fed with fruits of targuná tree (*Croton draco*). Normally in pairs, occasionally in small groups at fruiting trees. Not shy.
Breeding. Most nests in Apr or May, more rarely Mar and Jun, in Costa Rica, and two nests in Panama in Apr and May; mostly May in Trinidad; breeding apparently more protracted, with nests or breeding-condition birds from Jan–Sept, in Colombia. Sings mostly from cover, sometimes (mainly at dusk) during aerial display at up to 30 m above ground. Nest an open cup of slender dead vines, weed stems and similar material, with middle layer of dried grass stems, lined with finer grasses, tendrils and the like, external diameter c. 12–13 cm, cup c. 6–7 cm across, placed usually 1–3 m (more rarely up to 6 m) above ground in shrub or small tree. Clutch 2 eggs (Costa Rica; sometimes 3 in Trinidad), clear blue with variable amount of black or blackish spots or fine scrawls, markings concentrated around blunt end; incubation by female alone, sometimes fed on nest by male, period probably 13–14 days; chicks fed by both parents, nestling period c. 13 days; fledglings attended by both parents for several more days.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Over much of its range quite common. May benefit from forest clearance and subsequent recolonization by scrubland.

Genus *CYANOLOXIA* Bonaparte, 1850

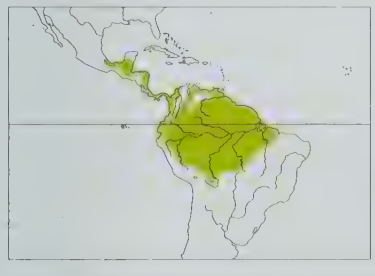
32. Glaucous-blue Grosbeak

Cyanoloxia glaucocaerulea

French: Évêque indigo **German**: Türkisbischof **Spanish**: Picogrueso Índigo
Other common names: Indigo/Glaucous Grosbeak

Taxonomy. *Pyrrhula glauco-caerulea* d'Orbigny and Lafresnaye, 1837, Maldonado, Uruguay.
Genus sometimes subsumed in *Passerina*. Apparent hybrids between this species and an unspecified *Oryzoborus* seed-finch (Emberizidae) reported from Brazil. Monotypic.
Distribution. Breeds NE Argentina (Misiones, Corrientes, Entre Ríos and NE Buenos Aires), SE Brazil (S São Paulo, Santa Catarina, Rio Grande do Sul) and N, E & W Uruguay; in austral winter, some move N as far Mato Grosso do Sul (S Brazil).

Descriptive notes. 14 cm; three birds 16–19·5 g. Male is deep dark sky-blue above (each feather having very narrow blackish terminal edging), brightest on forehead and rump; remiges blackish with some bluish edging, especially on tertials; rectrices blackish, edged blue on outer web; face deep sky-blue, area in front of eye more blackish; underparts deep sky-blue, becoming more greyish on lower belly; iris dark brown; upper mandible dusky with some grey around cutting edge, lower mandible greyish or dirty white; legs dark brown. Female is generally warm dark brown above, paler, more orange-brown, below. Immature male is mostly dark orangey-brown above, pale orange-brown below, with lower belly brighter, also bluish on forehead and cheek; blue feathers moult in to chest as bird increases in age.
Voice. Song, usually from concealed perch in dense cover, a fast, high, hurried jumbled warbling; call "psit" or "jit".
Habitat. Edges of low forest, bushes on humid river islands, marshes, second growth; from near sea-level to 1700 m in Brazil.
Food and Feeding. No published data on diet. Usually in pairs; generally rather shy.
Breeding. Nests Oct–Dec in Uruguay. Nest a cup of small twigs, placed at low or medium height in dense vegetation. Clutch 2–4 eggs, pale sky-blue with reddish spots distributed over entire surface. No other information.
Movements. Partial austral migrant. During austral winter, some move N as far as Mato Grosso do Sul, S Goiás and S Minas Gerais (all S Brazil) and SE Paraguay (mostly E of R Paraguay).
Status and Conservation. Not globally threatened. Generally rather rare to uncommon over much of range. Not well known.
Bibliography. Armani (1983), van Perlo (2009), Ridgely & Tudor (1989, 2009), Rocha (2006), Sick (1993).



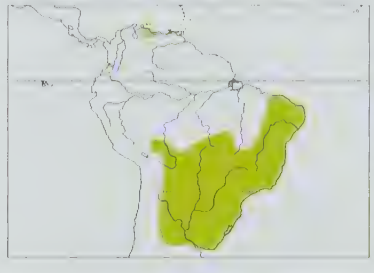
Genus *CYANOCOMPSA* Cabanis, 1861

33. Blue-black Grosbeak

Cyanocompsa cyanoides

French: Évêque bleu-noir **German**: Stahlbischof **Spanish**: Picogrueso Negriazul
Other common names: Rothschild's Grosbeak (*rothschildii*)

Taxonomy. *Coccoborus cyanoides* Lafresnaye, 1847, Panama.
Genus sometimes subsumed in *Passerina*; subspecific name *caerulescens* then becomes preoccupied, and replaced by *toddi*. Race *rothschildii* considered by some authors to represent a different species. Four subspecies currently recognized.
Subspecies and Distribution.
C. c. concreta (du Bus de Gisignies, 1855) – SE Mexico (Veracruz and N Oaxaca E to S Yucatán Peninsula), N Guatemala, Belize and Honduras.
C. c. caerulescens Todd, 1923 – Nicaragua S to W Panama.
C. c. cyanoides (Lafresnaye, 1847) – C & E Panama, NW Venezuela and N & W Colombia S (W of E Andes) to NW Peru (Tumbes).
C. c. rothschildii (E. Bartlett, 1890) – N, E & S Venezuela and the Guianas S to E Colombia, E Ecuador, E Peru, Brazil (S to N Mato Grosso and N Maranhão) and N & E Bolivia.



Descriptive notes. 17–18·5 cm; average 32·5 g. Male nominate race is rich deep blue above, rump somewhat paler blue, forehead and superciliary area slightly brighter blue than crown, slightly brighter blue shoulder patch; median and greater upperwing-coverts broadly edged deep blue, flight-feathers and rectrices dull blackish, narrowly edged deep blue; lores and area below eye blackish, chin blackish; throat and chest deep dark blue, becoming duller on lower belly and vent; iris dark brown; bill and legs blackish-grey. Female is uniformly dull chocolate-brown above and below; throat somewhat paler. Juvenile male is much like female, blue feathers first start to appear in forehead and around face, then on chest, full adult plumage not gained until autumnal moult of second year; juvenile female much as adult, may have obscure streaking on underparts. Race *caerulescens* male is decidedly darker blue, and larger, than nominate; *concreta* is similar to previous, but larger, male darker, more bluish-black, with throat and side of head distinctly blackish, female uniform rich brown; *rothschildii* male is much brighter than others, bright sky-blue on forehead, superciliary and malar regions and shoulder, female appreciably paler brown.
Voice. Song varies somewhat geographically: in Honduras 7–8 clear, flute-like notes, the first 4–5 rising slowly in pitch, the last 3 rapidly falling; in coastal Venezuela a few slow introductory notes, then a rich musical jumble of descending notes; other song patterns in other parts of South America. Female also sings, sometimes when incubating; male may sing in flight. Call a sharp metallic "chink"; also other low nasal or liquid calls.
Habitat. Humid evergreen forest, moist thickets, and dense vegetation. Sea-level to 1400 m in Venezuela; to 1200 m (one record at 2300 m) in Costa Rica; to 900 m in Mexico.
Food and Feeding. Diet probably mostly vegetable, including grass and bamboo seeds, maize (*Zea mays*) and rice; cracks seeds of *Psychotria brachiata* (Rubiaceae). Young fed mostly with mashed vegetable matter, also occasional insects. Generally in pairs. Typically forages low down in dense vegetation; will also venture well away from cover to eat maize and rice where available.
Breeding. Nest-building in Costa Rica starts in late Mar or Apr, earlier in wet Caribbean lowlands, but mostly in Jul–Aug; season mid-Mar to Jul in Belize, Feb through Oct in Colombia, and at least Mar and Apr in Brazil; two or three broods in a year in some regions. Nest built by both sexes, an open cup made from fine twigs, coarse fibrous materials and rootlets, placed 0·3–5 m up in spiny palm, tree-fern or similar plant; will nest also in maize fields with nearby woodland. Clutch usually 2 eggs, sometimes 1 (also 3–4 reported), bluish-white with brown dots at blunt end; incubation by female alone, fed on nest to variable degree by male, period 13–14 days; chicks fed by both parents, nestling period 11–12 days.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Common to fairly common in much of its range; widespread. Reported observations of race *rothschildii* in Trinidad are thought probably to be erroneous. Possibly benefits from presence of small grain fields alongside forested areas.
Bibliography. Armani (1983), Chubb (1910), Dallimer *et al.* (2005), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995), Lebbin (2006b), Moermond & Denslow (1985), Oniki (1984), Orians & Paulson (1969), Ridgely & Greenfield (2001a), Russell (1964), Salaman *et al.* (2008), Skutch (1954), Stiles & Skutch (1989), Todd (1923a).

34. Ultramarine Grosbeak

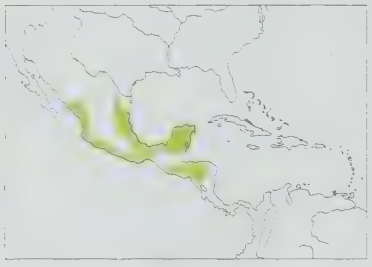
Cyanocompsa brissonii

French: Évêque de Brisson **German**: Ultramarinbischof **Spanish**: Picogrueso de Brisson
Other common names: Brazilian Blue Grosbeak

Taxonomy. *Fringilla brissonii* M. H. C. Lichtenstein, 1823, Bahia, Brazil.
Genus sometimes subsumed in *Passerina*. May form a superspecies with *C. parellina*.
Wild-bred hybrids with Double-collared Seedeater (*Sporophila caerulescens*), to which it is not closely related, have been reported in Brazil. Five subspecies recognized.
Subspecies and Distribution.
C. b. caucae Chapman, 1912 – SW Colombia in valleys of upper R Patía, R Cauca and R Dagua.
C. b. minor Cabanis, 1861 – mountains of N Venezuela (from Falcón and Lara E to Sucre and Monagas).
C. b. argentina (Sharpe, 1888) – E Bolivia (La Paz S to Tarija and Santa Cruz), S Brazil (W Mato Grosso), Chaco of Paraguay, and N Argentina (S to La Rioja, San Luis, Córdoba and N Buenos Aires).
C. b. brissonii (M. H. C. Lichtenstein, 1823) – NE Brazil from Piauí and Ceará S to Bahia.
C. b. sterea Oberholser, 1901 – E & S Brazil (from SE Mato Grosso, Goiás, Minas Gerais and Espírito Santo S to Rio Grande do Sul), E Paraguay, NE Argentina (Misiones and Corrientes) and Uruguay.

Descriptive notes. 15 cm; 27–28 g. Male nominate race has forehead, supercilium and cheek bright sky-blue, crown, nape and upperparts darker deep rich blue; shoulder patch bright medium-blue, feathers often having sky-blue streaks; flight-feathers and rectrices blackish; lores, area below eye and at base of bill, chin and throat blackish, becoming dark blue on chest and belly; lower flanks greyish-blue; iris dark brown; bill blackish-grey, often extensively paler grey around base of lower mandible; legs blackish. Female has upperparts warm brown, becoming more rufescent on rump; primaries and secondaries dull brown, lighter brown edgings on outer webs, rectrices dull blackish-brown; chin orange-buff, becoming brighter on belly. Juvenile male is orange-brown above and below, brighter and more orange below, with darker flecks on chest; blue feathers appear first on forehead and face, followed by abdominal region, and male may not attain full plumage until end of second year. Race *minor* is brighter blue on rump than nominate; *caucae* is smaller than nominate, similar to previous, but adult male has more ultramarine, less purple, on upperparts and underparts; *sterea* is smaller and darker than nominate; *argentina* is larger than nominate, male with larger frontal patch of silvery cobalt extending as spangled eyebrow to side of nape, female paler with light ferruginous-brown rump.
Voice. Song (in Venezuela) a rich series of rising and falling warbles, "we-se-weep wee so weep wee see wee-so-weep"; in Brazil, song described as flowing and melodious, alternating higher and lower cadences; dawn and dusk songs differ. Call a sharp metallic "pik".
Habitat. Thickets and other dense vegetation, also edges of *chaco*. In Venezuela and Colombia in arid or semi-arid desert scrub, dry forest borders, thickets etc., from sea-level to 1600 m, mostly below 900 m. In Argentina, race *argentina* occurs in shrubs and semi-open areas, sparsely as high as 2000 m, while *sterea* is found in denser forest.
Food and Feeding. No published data on diet. Usually found in pairs. Typically forages low down; generally difficult to see.
Breeding. Little information published, all of it referring to race *argentina*. Nest with eggs in mid-Dec. One nest was a cup of vegetable fibres, lined with finer fibres, external diameter 9 cm, height 7·5 cm, cup 5·5 × 5 cm, located 3 m up in a cornillo (*Schinopsis*) bush. One clutch, of 2 eggs, sky-

On following pages: 35. Blue Bunting (*Cyanocompsa parellina*); 36. Blue Grosbeak (*Passerina caerulea*); 37. Indigo Bunting (*Passerina cyanea*); 38. Lazuli Bunting (*Passerina amoena*); 39. Varied Bunting (*Passerina versicolor*); 40. Painted Bunting (*Passerina ciris*); 41. Rose-bellied Bunting (*Passerina rositae*); 42. Orange-breasted Bunting (*Passerina leclancherii*).



blue with fine chestnut spots all over, spots heavier at blunt end; other reports of clutches of 3 eggs, bluish-white or reddish-white, with pale cinnamon spots of variable extent. No other information.
Movements. Sedentary over most or all of range.
Status and Conservation. Not globally threatened. Quite common in many parts of range. Popular as a cagebird.
Bibliography. Barreira *et al.* (2007), Dinelli (1924), Hilty (2003), Hilty & Brown (1986), McCarthy (2006), de la Peña (2005), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Sick (1993), Todd (1923a).

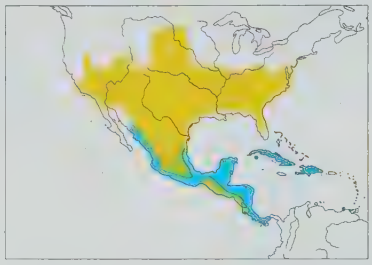
35. **Blue Bunting**

Cyanocompsa parellina

French: Évêque paré **German**: Lasurbischof **Spanish**: Picogrueso Azul

Taxonomy. *Cyanoloxia parellina* Bonaparte, 1850, Alvarado, Veracruz, Mexico.
Genus sometimes subsumed in *Passerina*. May form a superspecies with *C. brissonii*. Four subspecies recognized.
Subspecies and Distribution.
C. p. indigotica (Ridgway, 1887) – W Mexico from C Sinaloa S on Pacific slope to S Oaxaca and extreme SW Chiapas.
C. p. beneplacita Bangs, 1915 – NE Mexico (Nuevo León and extreme W Tamaulipas).
C. p. lucida Sutton & Burleigh, 1939 – NE Mexico (S interior Tamaulipas).
C. p. parellina (Bonaparte, 1850) – E Mexico (from Veracruz, E Puebla and N Oaxaca E to Tabasco, C Chiapas and Yucatán Peninsula) S to NW Nicaragua.

Descriptive notes. 13–14 cm; male 11–24 g, female 9·8–21 g (nominate). Male nominate race has forehead bright sky-blue, becoming deeper blue with darker feather bases on crown; area in front of and behind eye blackish, bright blue cheek patch; upperparts deep blackish-blue, rump bright ultramarine; shoulder ultramarine, upperwing-coverts deeper blue, remiges dull black, rectrices dull black with blue edging on outer webs; chin, throat, breast and belly deep blue, often becoming greyish-blue on lower flanks; iris dark brown; bill blackish, lower mandible often extensively paler bluish-grey; legs blackish-brown. Female is uniformly dull brownish, darker on primaries and secondaries, warmer and more rufescent on belly; bare parts as for male. Immature male is generally grey-blue above and below, with much suffusion of dull brownish, especially on belly; immature female much like adult female. Race *beneplacita* male is duller blue than nominate, female obviously paler, duller and less rufescent brown, bill smaller and blacker; *lucida* male is brighter throughout than previous, more blue, with less of a purplish hue on underparts, rump lighter, blue on crown extending evenly over hindneck to back, female duller and less rufescent than nominate; *indigotica* is slightly larger than nominate, male duller indigo-blue, paler cerulean blue on light areas, female lighter brown. Voice. Song a sweet, rather sad warble, often with one or two separate notes at start, fading away at end; call a metallic "chik" or "chink".
Habitat. Forest edge, scrubby areas, undergrowth of tall forest, and thickets. Sea-level to 1800 m in Mexico; to 900 m in Guatemala.
Food and Feeding. No published data on diet. Feeds singly and in pairs, low down in understorey.
Breeding. Birds in breeding condition in May in Belize. Nest a cup of rootlets, grass and plant tendrils, placed at low to medium level in bush. Clutch 2–3 eggs, unmarked, moderately glossy bluish-white. No other information.
Movements. Apparently mainly sedentary. Several records of vagrants in S USA (Texas, Louisiana), at distances of up to 800 km from nearest part of known breeding range.
Status and Conservation. Not globally threatened. Fairly common to common in much of range. Fairly common in Guatemala, where no records prior to 1906. Reported occurrence in Costa Rica in 2007 uncorroborated. Seems able to accept moderate modification of habitat.
Bibliography. Anon. (2007a), Cardiff & Remsen (1981a), Howell & Webb (1995), Land (1970), Russell (1964), Todd (1923a), Waide & Hailman (1977).



Genus *PASSERINA* Vieillot, 1816

36. **Blue Grosbeak**

Passerina caerulea

French: Guiraca bleu **German**: Azurfink **Spanish**: Azulillo Grande

Taxonomy. *Loxia caerulea* Linnaeus, 1758, South Carolina, USA.
Genus sometimes placed in family Emberizidae. This species formerly placed in monotypic genus *Guiraca*. Race *deltarhyncha* intergrades with *lazula* in Guatemala; former rather poorly differentiated, and sometimes synonymized with *eurhyncha*. Proposed race *mesophila* (Texas) included within nominate. Seven subspecies recognized.
Subspecies and Distribution.
P. c. salicaria (Grinnell, 1911) – breeds SW USA (C & S California, WC Nevada and SW Arizona) and extreme NW Mexico (NW Baja California); migrates to S Baja California and W Mexico (S Sonora S to Guerrero and Morelos).
P. c. interfusa (Dwight & Griscom, 1927) – breeds W USA (S South Dakota S to Arizona and New Mexico) and N Mexico (C Sinaloa, Durango and N Coahuila); migrates to W Mexico (Sonora and Durango) S to Honduras.
P. c. caerulea (Linnaeus, 1758) – breeds E USA from Kansas, Kentucky, SE Pennsylvania and S New Jersey S to C & S Texas, S Louisiana, C Alabama and C Florida; migrates to region from E & S Mexico S to Panama.
P. c. eurhyncha (Coues, 1874) – C & S Mexico from S Tamaulipas S to Oaxaca.
P. c. deltarhyncha (van Rossem, 1938) – Pacific slope in Mexico from S Sonora S to Guerrero.
P. c. chiapensis (Nelson, 1898) – S Mexico (E Oaxaca and Chiapas) E to S Guatemala.
P. c. lazula (Lesson, 1842) – S Guatemala, El Salvador and Honduras S through Pacific drainage to NW Costa Rica.

Descriptive notes. 15–19 cm; male 22–40·5 g, female 23–32·5 g. Breeding plumage attained through feather wear; after breeding, moults into fresh plumage (non-breeding). Breeding (worn) plumage has all body feathers blue except for a small black mask from lores and around bill down to chin, and undertail-coverts usually white-tipped, sometimes with remains of brownish tips here and there; lesser upperwing-coverts blue, some lesser and all median coverts chestnut, greater coverts blackish, edged blue and broadly fringed chestnut-brown on tips (two prominent bars on closed wing), primaries dull blackish-grey, narrowly edged whitish-brown on outer webs, secondaries similar but with bluer edgings, tertials usually with brownish remnants on edges of outer webs; rectrices greyish-black with bluish edgings, especially on central feathers, outer rectrix narrowly edged white; iris dark brown; bill mostly blackish above, silver below; legs greyish. Non-breeding (fresh) plumage has body feathers with fawn-brown edges, broad whitish edgings on undertail-coverts; bill horn; legs dull brownish. Female is medium-brown above, obscurely streaked dusky on mantle and scapulars, with some bluish, especially on lower back and rump, paler below, throat pale orange-brown, deeper-toned on chest; diffuse dull chestnut band on shoulder, some bluish on lesser upperwing-coverts, median coverts dusky, with tawny band reduced to broad tips, rest of wing similar to that of male but edgings are tawny to buff; bare parts as for non-breeding male. Juvenile is entirely brown in both sexes, although some males have traces of blue on bases of rectrices. Race *interfusa* is larger and paler than nominate, blue of male less purplish, anterior wingbar paler chestnut, posterior wingbar paler still; *salicaria* is closest to previous, but bill smaller, plumage generally paler, wing and tail on average longer; *eurhyncha* is similar to nominate in tone, but larger, with upper wingbar deep chestnut, bill larger; *deltarhyncha* male is darker than last; *lazula* is similar to *eurhyncha*, but male paler and much brighter blue; *chiapensis* is closest in plumage to last, but darker, larger and larger-billed. Voice. Song, from elevated perch or within cover, a series of rich warbled notes, in sequence lasting for up to 4 seconds, irregularly alternating up and down in pitch; nature of song varies according to stage of nesting, when female receptive male's song has more variants, with more versatile arrangement of elements, than when she is engaged in incubation; singing rates also up to three times higher during pre-pairing period than when female on eggs. Calls include metallic "tink", probably used in alarm; low buzzy note, "bzzzt"; high, rolling "preet"; also various other short calls.
Habitat. In E North America inhabits forest edge, regenerating farmland and open-pit mines, streamsides etc., often with medium-sized trees; in California, dense low vegetation near water; in Mexico, deciduous or semi-deciduous scrub, semi-open areas, often near water; in Costa Rica, from sea-level to 1100 m, often in tropical dry forest as well as in more humid zones. In non-breeding season found in brushy fields, areas with scattered trees and similar places. On migration various habitats, e.g. flocks found in rice fields.
Food and Feeding. Diet mixed animal and vegetable; in one extensive study of stomach contents of birds of all ages, 32% vegetable and 68% animal. Seeds of various plants, especially grasses, also wheat (*Triticum*) and oats (*Avena sativa*). Wintering birds in Guatemala seen to forage on waste grain in mule corrals. Animal matter mostly arthropods, e.g. caterpillars, beetles (Coleoptera), grasshoppers (Orthoptera), bugs (Hemiptera), treehoppers (Membracidae). Nestling diet almost exclusively animal matter, especially grasshoppers, also caterpillars and snails (Gastropoda). Opportunistic feeder, taking advantage of temporary abundances of prey, e.g. cicadas (Cicadidae) during period of emergence, or mantids (Mantidae). Feeds both on ground and in vegetation, sometimes by aerial flycatching.
Breeding. Virtually all studies have been on North American populations; few data on Middle American races. First egg dates from mid-Apr in California, May in Texas E to Carolinas, and Jun in Colorado and Indiana, and in arid SW USA may time nesting to coincide with summer rainy period; nestlings in Jul in Guatemala and nest-building May–Jul in Costa Rica; double-brooded, at least in S USA. Remarkable rate of extra-pair fertilizations, e.g. in one study 53% of nestlings (involving 70% of all nests) were result of cuckoldry by other males; males with brighter blue plumage tend to have larger and better territories than duller males, and they also had higher rates of cuckoldry and lower rates of being cuckolded; male also adjusts its mate-guarding behaviour according to attractiveness of neighbouring males, those with brightly coloured neighbours tending to guard mate more closely than do those having duller neighbours (but in study of captives, females did not prefer males with plumage artificially brightened over those which had been made more dull). Nest built mostly by female, male occasionally participating in work, a compact cup of twigs and rootlets, dead leaves, corn husks and similar, often with snakeskin and artificial material (e.g. cellophane, rags, etc.), cup diameter 6–8 cm, lined with finer grasses, hair, rootlets and the like, in Costa Rica often held together by spider webs; one nest in Oklahoma was built entirely from newspaper, though lined with fine roots; situated from 15 cm to 8 m up in shrub, vine tangle or small tree. Clutch 3–5 eggs, usually 4, pale bluish-white or blue, exceptionally with light brown streaky (not spot-like) markings; incubation by female alone, period 11–12 days; chicks fed mostly by female, though male more involved after young fledge, especially if female building another nest; fledging 9–13 days. Frequent host of both Brown-headed (*Molothrus ater*) and Bronzed Cowbirds (*Molothrus aeneus*), e.g. at least 50% of nests in one Arizona study were parasitized, and 10–20% in other studies. Although this species successful in rearing its own young in mixed broods, overall productivity is reduced by cowbird parasitism.
Movements. N races (nominate, *salicaria* and *interfusa*) totally migratory; other races appear to be sedentary. Nocturnal migrant. In autumn, leaves South Dakota mid-Aug to mid-Sept, migration continuing through Oct in other areas; E populations probably fly across Gulf of Mexico, as species occurs as migrant rather uncommonly in Bahamas and Cayman Is, more rarely in Cuba and Hispaniola (where small numbers overwinter), very sparsely elsewhere (including Puerto Rico), and very rarely Jamaica and Virgin Is. Return from mid-Apr in S California to middle/late May in South Dakota; among migratory populations, males arrive back on territory before females. Fairly frequent vagrant N of range, e.g. in S Canada (Ontario) and NE USA (Massachusetts and other places), and some winter records in New England; in S, vagrant in Bahamas, N Colombia and NE Ecuador.
Status and Conservation. Not globally threatened. Reasonably common, but never regarded as an abundant species. Fairly common over much of its USA range; fairly common to common breeder in Mexico; uncommon to fairly common in Costa Rica. In USA, greatest densities on E seaboard from Virginia and North Carolina S to Georgia. May benefit from abandonment of farmland and regenerating vegetation of open-pit mine sites.
Bibliography. 37. Indigo Bunting

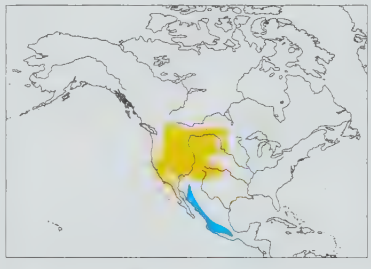
Passerina cyanea

French: Passerin indigo **German**: Indigofink **Spanish**: Azulillo Índigo

Taxonomy. *Tanagra cyanea* Linnaeus, 1766, South Carolina.
Genus sometimes placed in family Emberizidae. May form a superspecies with *P. amoena* and often treated as conspecific; the two hybridize extensively. Hybrids reported rarely also with *P. ciris* and, in captivity, with *P. leclancherii*; has hybridized also with captive domestic Island Canary (*Serinus canaria*). Monotypic.
Distribution. Breeds E North America, from S Canada (SE Saskatchewan and S Manitoba E to S New Brunswick) S in USA to W Kansas and C Texas across to Gulf Coast and E seaboard, also W into New Mexico and S Arizona. Migrates to Middle America from C Mexico (S Tamaulipas) S to E Panama and West Indies.



Descriptive notes. 14 cm; male 12·5–17·5 g, female 11·9–18·5 g (Michigan, in N USA). Male breeding has crown deep indigo, becoming more blue on nape and upperparts, feathers of back with dark blackish-grey bases (sometimes showing through); shoulder bright blue, alula mostly blackish, lesser upperwing-coverts bright blue, median and greater coverts dusky blue, broadly edged bright blue, tertials blackish with broad blue edgings; primaries and secondaries greyish-black, narrow bluish edgings on outer webs; rectrices blackish-grey, edged bright blue; chin and throat bright indigo, darker on lores, chest indigo, becoming more blue on sides and on belly, thigh and vent; iris dark chestnut; bill blackish above, blue-grey to whitish below; legs dull blackish. Male non-breeding is similar to female, but with much blue around head and body. Female is entirely medium-brown above, more grey-brown on shoulder (many individuals with blue tinge on shoulder, primary coverts and edges of rectrices); median and greater coverts grey-brown, edged paler brown; primaries and secondaries dull blackish-brown, tertials blackish-brown, broadly edged brown, rectrices dull brown; face buffy brown, chin and throat dull whitish-buff, chest medium-brown with obscure broad streaking, belly brownish-white, becoming darker on flanks and lower belly; bare parts as for male. Juvenile is generally dark brown all over, paler on lower chest and belly, some males with blue edgings on rectrices; male takes two years to gain full plumage, some older males may still retain substantial amount of brown on body feathers.
Voice. Song, usually from prominent elevated perch, more rarely in flight, a loud, cheerful series of robust high notes, 6–20 or more in a series, "swee-swee-swee" and so on, sequence sometimes lasting up to 6 seconds (usually 2–3). Much individual variation; males in neighbouring territories often have very similar songs, while more distant males may use different song type. Apparently only males sing; reports of female song may involve immature males. Begins to sing on spring migration, and on arrival on territory sings very persistently, throughout day, even on hot sultry afternoons. In range of sympatry with *P. amoena* the two share some elements of songs and often respond strongly to heterospecific song, whereas male response to heterospecific song weak in allopatric populations; females, however, respond much more to song of own species than to that of the other species. Calls mostly monosyllabic, "chip" and similar, sometimes in protracted series at times of agitation; female soliciting copulation may give trilling or twittering call.
Habitat. Woodland edge, bushy areas and successional bush along roadsides, riverside vegetation, clearings in woodland; usually not in interior woodland with unbroken canopy. On migration and on wintering grounds found in weedy cropland, low second growth, savanna and recently harvested rice fields.
Food and Feeding. Diet varies during year. In winter predominantly vegetable matter, including weed and grass seeds, rice and similar items. During breeding season much more animal matter, including spiders (Araneae), various insects such as caterpillars, bugs (Hemiptera), beetles (Coleoptera) and grasshoppers (Orthoptera), as well as seeds and berries. Nestling diet mostly animal matter, including caterpillars, spiders and their egg cases, grasshoppers and dragonflies (Anisoptera), as well as berries. In pairs; also in small flocks outside breeding season.
Breeding. Egg dates mid-May to mid-Aug, rarely later, in N of range (Ontario and Michigan), somewhat earlier in S; up to four clutches in a season (some probably replacements). Female may remain with same male for subsequent broods after first, or may change mates. Some males polygynous. Extra-pair copulations common; in one study, 35% of nestlings came from extra-pair copulations, and 48% of broods had at least one individual not sired by male nest-owner. Nest built entirely by female, on site chosen by her, male may accompany her during construction, an open cup of soft leaves, dried grasses, bark strips, rootlets and the like, often with spider webs around rim, occasionally snakeskin, lined with fine grass and hair, external diameter c. 9 cm, internal c. 4–6·5 cm, placed usually low down, 0·3–1 m (rarely up to 10 m) above ground, in bush or small sapling, or in herbage such as goldenrod (*Solidago*). Clutch usually 3–4 eggs, sometimes 2, larger clutches more common in early broods (clutches of up to 6 eggs probably due to two females laying in one nest), usually unmarked whitish or very pale bluish-white or greenish-white, rarely with purplish or brownish-red spots; incubation by female alone, period 11–14 days (usually 12–13 days), male may remain nearby and give alarm at intruders; small chicks brooded by female alone, fed almost exclusively by female, in some cases male may feed older nestlings; no information on duration of nestling period; fledglings fed largely by female, though male may help, and as they get older sometimes fed entirely by male; older males (i.e. after second-year) may be more attentive to feeding than are second-years, perhaps because of higher chance of their being the brood's genetic father (polygynous males significantly less likely to feed young). Frequent host of Brown-headed Cowbird (*Molothrus ater*); in studies in Michigan and Ontario, 20–25% of nests parasitized, sometimes with several cowbird eggs (later broods, when cowbirds have finished laying, less parasitized). Nesting productivity significantly worse in parasitized nests, especially when more than one cowbird egg laid.
Movements. Migratory; essentially no overlap between breeding and wintering ranges. Nocturnal migrant. Autumn migration starts late Aug in N (Ontario), Sept to Oct farther S; those wintering in Middle America may travel both around and across Gulf of Mexico; winters regularly in Greater Antilles and occurs on migration, but not as wintering resident, on offshore cays of Belize and islets N of Yucatán. Return to breeding grounds late Apr to early Jun, N populations being later, and males arriving on territory 1–2 days before females. Ring recoveries reveal that birds are quite strongly philopatric on wintering grounds. Vagrant N to British Columbia, shores of Hudson Bay, S to Coco I (S of W Costa Rica), Providencia, San Andrés, Trinidad, Netherlands Antilles, N Colombia and Venezuela; also Iceland, NW Russia (Curonian Spit), Ireland, Britain, Netherlands, Azores (numerous records). Some extralimital records may involve escaped cagebirds.
Status and Conservation. Not globally threatened. Common to abundant over much of its range; in some areas (e.g. Kentucky and Tennessee) regarded as the most common nesting bird. Population estimates, based on Breeding Bird Survey routes, vary from 10,000,000 to 40,000,000 breeding pairs, although latter figure may be an overestimate. Has recently extended range W into New Mexico and S Arizona, where more sparsely distributed. May benefit from clearing of woodland, also from defoliation of trees in formerly dense stands by introduced gypsy moths (*Lymantria dispar*). Population reduced by more intensive agriculture, more frequent mowing of roadside verges and urbanization. Popular as a cagebird in Mexico and Central America, but this unlikely to have any significant effect on population. A favourite species for scientific investigation of migration physiology and navigation.
Bibliography. Baker (1991, 1994, 1996), Baker & Boylan (1995, 1999), Belcher & Thompson (1969), Bell & Whitmore (2000), Blake (1969), Bradley (1948), Carey (1982), Carey & Nolan (1979), Carling & Brumfield (2008a, 2008b, 2009), Carling *et al.* (2010), Dearborn (1996), Downer (1972), Emlen (1967a, 1967b, 1969, 1970, 1971a, 1971b), Emlen, Rising & Thompson (1975), Emlen, Wiltschko *et al.* (1976), Fisk (1979), Forsythe (1974), Howell (1989), Hylton & Godard (2001), Johnston (1965, 1967, 1970), Johnston & Downer (1968), Keith *et al.* (2003), Koblik *et al.* (2006), Kopachena & Crist (2000a, 2000b), Krementz & Christie (2000), Kroodsma (1975), Lücking & Lücking (1994), MacLean (1886), Margoliash *et al.* (1991, 1994), McCarthy (2006), Morris (2005), Olafson (1993), Payne (1981, 1982, 1983, 1991, 1992, 1996, 2006), Payne & Payne (1989, 1990, 1993a, 1993b, 1996, 1998), Payne & Westneat (1988), Payne, Payne & Doehlert (1988), Payne, Thompson *et al.* (1981), Pyle (1997), Quay (1987), Rice & Thompson (1968), Rohwer (1986), Russell (1964), Schill & Yahner (2009), Shiovitz (1975), Shiovitz & Thompson (1970), Sibley & Short (1959), Sniegowski *et al.* (1988), Taber & Johnston (1968), Taylor *et al.* (1989), Thompson (1970), Van Tyne (1932), Weldon & Haddad (2005), Westneat (1987a, 1987b, 1988a, 1988b, 1990), Wiltschko *et al.* (1980), Wormington (1986), Young (1989).

38. Lazuli Bunting

Passerina amoena

French: Passerin azuré **German**: Lazulifink **Spanish**: Azulillo Lapislázuli

Taxonomy. *Emberiza amoena* Say, 1822, near Canyon City, Colorado, USA.
Genus sometimes placed in family Emberizidae. May form a superspecies with *P. cyanea* and often treated as conspecific; the two hybridize extensively. Monotypic.
Distribution. Breeds SW Canada (SE British Columbia, SW & extreme S Alberta and S fringe of Saskatchewan), W USA from C Washington and Oregon and most of California (except SW) E to W North Dakota and South Dakota, NW Nebraska, EC Colorado, N New Mexico and Arizona, and extreme NW Mexico (NW Baja California). Migrates to SE Arizona S through W Mexico to NW Oaxaca.

Descriptive notes. 13–14 cm; male 13–19·5 g, female 12·7–16·9 g (California). Male has head, chin, throat and upper chest bright lazuli-blue, becoming suffused with darker on mantle, back and scapulars; rump lazuli-blue; primaries greyish-black with bluish edgings on outer webs; median upperwing-coverts broadly tipped whitish and greater coverts more narrowly tipped whitish (two wingbars on closed wing); rectrices dull greyish-black, suffused with bluish, especially on outer webs; chest chestnut-brown, lower chest and belly off-white; iris black; upper mandible black, lower mandible light bluish-grey; legs dark brown or black. Male non-breeding is similar to breeding, but plumage brightness obscured by extensive buff feather tips. Female is uniformly greyish-brown above, becoming more grey or bluish on rump; whitish-buff below, with stronger buff on chest and pale buffy grey on belly; lesser upperwing-coverts with bluish tinge, median coverts dusky with broad buffy-white to dull buff tips, greater coverts dusky with brownish-buff fringes and broad tips forming a second, usually less contrasting, wingbar; bare parts as for male. Juvenile is entirely brown, and can probably not be reliably sexed until after some coloured fresh body feathers (blue or orange on male, brown on female) appear in Oct of first year.
Voice. Song a cheerful series of variously phrased warbling whistles, sometimes paired, often ending in buzz; similar to that of *P. cyanea*, but less strident and considerably faster (in areas of allopatry, the two are usually indifferent to playback of the other species' song; where both species occur, each reacts aggressively to other's song). In sympatric areas each species may use some phrases borrowed from the other's song. Considerable variation of song type, but individuals tend to stick to one type, which is apparently learnt during first year and then remains fairly constant. Calls include short "chip" when agitated, either by humans or by other species, or in territorial disputes; during copulation and pre-copulation a "tseep" from male and a "ti-ti-ti-ti" from female; alarm calls include a trill and "seet"; loud, strident distress call, "eeee", used when nest or fledglings threatened. Various other calls described.
Habitat. Breeds in wide variety of brushy habitats, including arid brushy hillsides, wooded valleys and open scrub. To 3000 m in Sierra Nevada of California, and to 2400 m in NW Mexico and 2000 m in W Mexico. Rapidly colonizes new regenerating scrubland. On wintering grounds occurs in overgrown fields, thorn-forest, roadside verges and similar places.
Food and Feeding. Food predominantly vegetable, mainly fruits and seeds of such plants as chickweed and wild oats (*Avena*), but also substantial amounts of animal matter, especially during spring and summer. Invertebrate prey includes caterpillars, small spiders (Araneae), bugs (Hemiptera), beetles (Coleoptera) and ants (Formicidae). Forages singly and in pairs; in non-breeding season also in small loose flocks. Picks up seeds from ground; perches in grasses to eat seedheads. Insect prey usually gleaned from leaf surfaces. Both sexes also flycatch, in short flights.
Breeding. Season May–Sept, mostly Jun–Aug; usually double-brooded. Monogamous; male occasionally polygynous. Nest-site chosen by female, she also exclusively responsible for construction of nest, an open cup of rootlets, grasses, bark strips and similar material, often with caterpillar silk or spider webs on outside, cup lined with finer grasses and animal hairs, external dimensions 8–11·5 cm, cup diameter 4–7 cm, depth 3–5·5 cm, usually low down, mostly below 1 m (only rarely up to 2 m), in low shrub, tangle or sapling. Clutch usually 3–4 eggs, sometimes 1 or 6 (though large clutches may come from more than one female, and small ones due to activities of cowbirds), pale bluish-white or greenish-white, sometimes pure white, unmarked; incubation by female alone, period 11–14 days, average c. 12 days; chicks fed by both sexes, mostly by female, in individual cases male may provide none or up to 50% of all food, nestling period 9–11 days, shorter if nest disturbed; young fed by parent or parents for up to two weeks after leaving nest; if pair starts a

second breeding attempt, the feeding and post-fledging care of the first brood are often done exclusively by male while female is incubating. Frequent host of Brown-headed Cowbird (*Molothrus ater*), e.g. in California (Sacramento Valley) and in one area of W Montana parasitism rates may approach 100% (and one nest near cowbird roost contained ten cowbird eggs), but in one study in S Canada (Alberta, at edge of present species' range) no parasitism found. Effect on nesting success of cowbird parasitism varies according to hatching times: if young cowbird hatches simultaneously with, or before, the host's young, few or none of latter fledge; if host chick has a head-start of 2–3 days it seems able to compete for food with the cowbird chick. Breeding success seems to be more deleteriously affected by cowbirds than is the case with *P. cyanea*, perhaps because of relative paucity of food in dry habitat.

Movements. Entirely migratory; no overlap between breeding and wintering ranges. Nocturnal migrant. Leaves territories in Jul or mid-Aug, when small flocks found; autumn migration interrupted for about a month while birds undergo moult involving flight-feathers and most of body feathers (this occurs in S Arizona, SW New Mexico and S Baja California), after which they proceed to wintering areas in S USA (SE Arizona) and W Mexico (mainland; formerly wintered also S Baja California). Return to breeding areas from early Apr (in Texas and S California) to late May (Wyoming) and early Jun (at N end of range in Alberta), males arriving on territory 4–6 days before females. Extralimital records have occurred widely in North America, N & E to Ontario, Nova Scotia, Maine, Virginia, South Carolina and Florida, as well as in E Atlantic in Faroe Is and arctic Norway; in some cases, question of vagrancy complicated by possibility of escapes from captivity.

Status and Conservation. Not globally threatened. Quite common or even abundant in suitable habitat over much of its range. Some populations under heavy, possibly unsustainable, pressure from Brown-headed Cowbird, which has benefited from human-induced habitat changes. Has been suggested that, in Sacramento Valley, the rate of nest loss due to cowbird parasitism may be such that local populations of present species are sustained only by constant replenishment from outside. In Mexico, frequently taken as a cagebird, although this unlikely to be a major drain on population.

Bibliography. Baicich & Harrison (2005), Baker (1991, 1994), Baker & Baker (1988, 1990), Baker & Boylan (1995, 1999), Baker & Johnson (1998), Carling & Brumfield (2008a, 2008b, 2009), Carling *et al.* (2010), Cook (1977), Emlen *et al.* (1975), Erickson (1968), Gardali *et al.* (1998), Greene *et al.* (1996), Kroodsma (1975), Leidolf *et al.* (2007), Maybank (1985), Maybank & McKenna (1997), McCarthy (2006), Michaelson (1985), Muehter *et al.* (1997), Phillips *et al.* (1964), Rothstein (1994), Russell & Monson (1998), Sauer *et al.* (1997), Sibley & Short (1959), Stokes (1993), Thompson (1968, 1969, 1976), Young (1991).

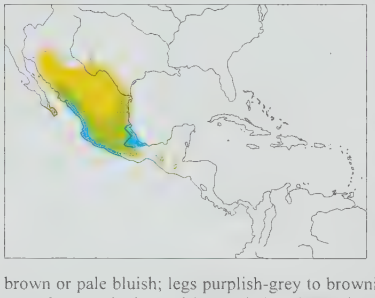
39. Varied Bunting

Passerina versicolor

French: Passerin varié **German**: Vielfarbenfink **Spanish**: Azulillo Morado
Other common names: Versicolour Bunting

Taxonomy. *Spiza versicolor* Bonaparte, 1838, near Temascaltepec, Mexico.

Genus sometimes placed in family Emberizidae. This species has hybridized with *P. ciris*. Races *pulchra* and *purpurascens* considered by some authorities to be too weakly differentiated to be tenable. Four subspecies currently recognized.



Subspecies and Distribution.

P. v. dickeyae van Rossem, 1934 – breeds S USA (C & S Arizona, S New Mexico) and W Mexico (Sonora and WC Chihuahua S to Colima).

P. v. versicolor (Bonaparte, 1838) – breeds S USA (S New Mexico; S Texas from Big Bend to Rio Grande Valley) and S through C Mexico to Oaxaca.

P. v. pulchra Ridgway, 1887 – S Baja California (Mexico).

P. v. purpurascens Griscom, 1930 – S Mexico (Chiapas) and S Guatemala (Motagua Valley).

Descriptive notes. 11–14 cm; male average 13 g, female average 12·8 g. Male nominate race has forehead and area between bill and eye down to chin blackish, crown bright violet-blue, becoming more reddish-purple on nape; ear-coverts are violet-blue, strongly tinged purplish-pink; upperparts dark purplish-pink, almost black, becoming deep azure-purple on rump; primaries and secondaries greyish-black, rectrices blackish, tinged with purplish; throat reddish, chest deep pinkish-purple, becoming darker and bluer on lower belly; iris dark brown or greyish-brown; upper mandible blackish to dark lead-grey, lower mandible light horn-brown or pale bluish; legs purplish-grey to brownish-black. Female is fairly uniformly brownish-grey above, paler brownish-grey below, becoming paler grey on lower belly; bluish tinge on wings and tail, and variably and patchily over upperparts; bare parts as for male. Juvenile is entirely brownish, sexes indistinguishable until some fresh purple or red (male) or brown (female) body feathers appear, which may not be until second year. Race *pulchra* is smaller than nominate, with shorter tail and wing, male nape patch brighter red, throat less reddish (never decidedly red), flanks brighter plum-purple, rump more purplish-blue or lavender, female greyer, especially below and on sides of head and neck; *dickeyae* is smaller than nominate, male red nuchal patch larger and brighter than previous, female and immature male rufescent brown, not greyish-brown; *purpurascens* is smaller and darker than nominate. Voice. Song a rich series of short, rapidly repeated phrases or syllables, lasting for 3–6 seconds; older individuals use a more prolonged series. Calls include short "chip" or "buzz" notes, given as alarm.

Habitat. Dry scrubland, thorn-scrub, acacia (*Acacia*) thickets and similar; in Mexico found in deciduous thorn-forest, overgrown clearings etc., from sea-level to 2000 m. Sometimes in more humid forest edge on wintering grounds.

Food and Feeding. In summer, mixed animal and vegetable diet. Invertebrate prey includes caterpillars, small grasshoppers (Orthoptera), beetles (Coleoptera), ants (Formicidae), termites (Isoptera) and ant-lions (Myrmeleontidae); vegetable matter includes seeds of grasses and other plants, prickly pear (*Opuntia*) fruit, berries. Nestling diet invertebrates (caterpillars, grasshoppers etc.). No data on diet in wintering areas. Forages singly and in pairs; also in small flocks in non-breeding season. Feeds on ground and in vegetation; seen to pluck at spider webs. Sometimes flycatches for aerial prey.

Breeding. Season mid-Apr to mid-Jul; said to be single-brooded in S Arizona, but in Texas apparently double-brooded. Male strongly philopatric. Pair-bond may be maintained for repeated nesting through breeding season or even into succeeding years; female may switch territories, and hence mates, between years, but not observed to do so between broods. Nest built by both sexes (unlike congeners in North America), an untidy cup of dry grasses, small weed stems, plant fibres, plant down and similar material, sometimes snakeskin incorporated, lined with fine grasses, hair and rootlets, external diameter 6·5–8 cm, cup 4·5–6·5 cm, placed 0·7–1·3 m (occasionally to 4 m) above ground, usually in thorny scrub. Clutch 2–5 eggs, most commonly 4, bluish-white or greenish-white, unmarked or lightly speckled with brownish markings; incubation by female alone, period c. 14 days; female alone broods small young, young fed initially only by female, male helps after c. 4–5 days, nest sanitation by both sexes, young can leave nest, especially if disturbed, in c. 10 days; after fledging, brood may split, typically two young being cared for by each parent; young may then rejoin into one group, cared for by male, while female starts second brood. Nests parasitized by Brown-headed Cowbird (*Molothrus ater*), but few data on frequency, and little information on impact on nest success.

Movements. Sedentary in S of range, although some of those breeding in S Baja California (race *pulchra*) may migrate across Gulf of California to mainland Mexico (Sonora and Sinaloa). N populations migratory, making post-breeding movement to S parts of breeding range and to coastal areas of Mexico. Nocturnal migrant, so far as can be determined. Leaves breeding grounds mostly by late Aug; returns in Texas about mid-Apr, males arriving on territory before females. Vagrant recorded in SE USA (Florida) in Jun 2005.

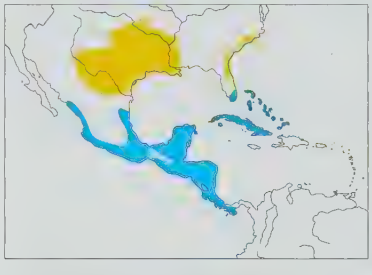
Status and Conservation. Not globally threatened. Classified as "Declining" in USA (Yellow WatchList priority species for conservation). Locally common to uncommon. Has decreased in some parts of former range owing to conversion of habitat to agriculture; now rare in lower Rio Grande Valley. Overgrazing by cattle and (in Mexico) goats causes habitat degradation, as have various road-building and mining operations in USA–Mexico border region. In New Mexico declared as "threatened". Popular cagebird in Mexico, but effect, if any, on populations not known.

Bibliography. Baicich & Harrison (2005), Groschupf & Thompson (1998), Howell & Webb (1995), Lebbin *et al.* (2010), Lockwood (1995), McCarthy (2006), Meitzen (1967), Phillips *et al.* (1964), Pulich (1963), Russell & Monson (1998), Storer (1961), Todd (1987), Walker (2009), Woolfenden & Van Deventer (2006).

40. Painted Bunting

Passerina ciris

French: Passerin nonpareil **German**: Papstfink **Spanish**: Azulillo Sietecolores
Other common names: Nonpareil



Taxonomy. *Emberiza ciris* Linnaeus, 1758, South Carolina, USA.

Genus sometimes placed in family Emberizidae. In the wild, present species rarely hybridizes with other members of genus; crosses with *P. cyanea* and *P. versicolor* described. In captivity has hybridized with *P. cyanea* and with domestic Island Canary (*Serinus canaria*). Races poorly differentiated and widely separated geographically, and they differ significantly in migration and moult strategies, suggesting that there is very little gene flow between them, and that they perhaps warrant treatment as two separate species; further study required. Two subspecies currently recognized.

Subspecies and Distribution.

P. c. ciris (Linnaeus, 1758) – breeds on US Atlantic seaboard from North Carolina S to C Florida; migrates to S Florida, Bahamas and Cuba.

P. c. pallidior Mearns, 1911 – breeds in S USA (SE Kansas E to W Tennessee and Mississippi, S to C & S New Mexico and Texas) and adjacent Mexico (Chihuahua E to NW Tamaulipas); migrates to Mexico (S from C Sinaloa, S San Luis Potosí and S Tamaulipas, but absent from central highlands) and S to W Panama.

Descriptive notes. 13 cm; male 13·3–19 g, female 12·9–19 g (Florida). Male nominate race has head deep blue, rose-pink eyering; upperparts copper-green, rump pinkish-rose; lesser upperwing-coverts dull, dark green-blue, median coverts bronze to maroon, greater coverts green, remiges dusky with dull bronze to dull green on outer webs; rectrices dark grey-brown, suffused with pinkish-brown; chin and throat rose-red, chest rose-red with deep blue at side, remainder of underparts somewhat paler rose-red; iris dark brown; bill blackish or dark brown; legs dull brown or dusky brown. Female is uniformly olive-green above, becoming brighter green on rump; primaries dull dark greyish with green edgings (giving greenish area on closed wing), rectrices dark greyish, strongly tinged with green on outer webs; dull yellowish-green below, greyer on chest, brighter yellow on belly; bare parts as for male. Juvenile on leaving nest is entirely dull brownish, becoming more bright greenish after body-moult (about Oct); sexes not separable in most instances until subsequent moult. Race *pallidior* is larger and paler than nominate, but differences clinal and complicated by individual variation. Voice. Only male sings. Song a series of high-pitched whistled notes, in phrases of 1–3 notes, totalling c. 10 syllables, lasting for up to 2 seconds; generally described as less loud than that of *P. cyanea*, and with tinkling quality. No apparent constant differences in songs between E & W populations. Calls include "pik-pik-pik" and "chip", sometimes used in agonistic situations.

Habitat. Areas of scattered bush, recently abandoned farmland, disused orange groves, riparian thickets; uses wooded areas in otherwise open habitat, in contrast to *P. cyanea* (which typically uses open areas in woodland). In wintering areas found in overgrown shrubby pasture, forest edge, clearings and similar habitats; sea-level to 1400 m in Honduras, to 1800 m in Mexico and to 1850 m in Guatemala.

Food and Feeding. On breeding grounds predominantly vegetable, including seeds of various grasses, sedges (Cyperaceae), some dicotyledons including spurges (*Euphorbia*), figs (*Ficus*) and wood sorrel (*Oxalis*). In one extensive study of stomach contents, 79% vegetable, 21% animal. Animal prey mostly arthropods, including caterpillars, grasshoppers (Orthoptera), boll weevils (*Anthonomus grandis*) and other beetles (Coleoptera), sometimes spiders (Araneae) and snails (Gastropoda). Nestling food largely or entirely animal, e.g. caterpillars, beetle larvae, grasshoppers. Few data on winter diet. Singly and in pairs; outside breeding season also in small groups, and frequently joins flocks of other granivorous birds. Forages mostly on or near ground, though higher up in breeding season.

Breeding. Nest-building from late Mar in SW, early May to mid-May elsewhere; usually two broods, occasionally three. Mostly monogamous, but polygyny not uncommon. Nest built entirely by female, starting within a few days of arrival on site and often complete in two days, a neat, deep, thin-walled cup c. 8 cm in external diameter, cup c. 5·5 cm across, made of grasses, fine weed stems and similar materials, occasionally incorporating artificial matter such as tissue paper, bound together by cobweb, sited 0·3–2·5 m up in low vegetation, rarely up to 15 m above ground. Clutch 3–4 eggs, sometimes 2 (rarely 5), pale bluish-white or greyish-white, quite heavily speckled (unusual for

genus) with russet or chestnut-brown; incubation by female alone, period 11–12 days; chicks fed only by female, nestling period 9 days; recently fledged young very poor flyers for first couple of days, attended mostly by female, sometimes (about a quarter of cases in one study) assisted by male; if female involved in a second brood, male may take exclusive charge of fledglings; parental care may extend to about three weeks after departure from nest. Nests quite frequently parasitized by Brown-headed (*Molothrus ater*) and Bronzed Cowbirds (*Molothrus aeneus*): W population co-evolved with cowbirds and has developed some defences, primarily by abandoning parasitized nests, e.g. in one Oklahoma study almost a third of nests parasitized but almost three-quarters of these were subsequently deserted; eggs of W population thicker-walled than those of E population, perhaps to prevent puncturing by cowbirds; relatively little information on E population, where parasitism rates seem to be lower.

Movements. Almost totally migratory; winters casually in extreme S Louisiana and SE Texas, otherwise breeding and wintering areas do not overlap. Nocturnal migrant. W population moves S from late Jul to Oct, substantially earlier than E one (moves from late Sept to late Oct, with smaller numbers into early Nov), this difference a result of different moult strategies: W birds move short distance into specific areas of S Arizona (irregularly) and Sonora, pausing to moult before continuing on to wintering grounds as far S as Panama; those from E seaboard complete moult on breeding grounds before proceeding, without interruption, to wintering grounds. Birds in S Florida strongly faithful to wintering areas. Both arrive back on breeding grounds in Apr, or early May in N parts of range, males usually on territory several days before females. Many extralimital records, in W from Oregon and Nevada S to California and S Baja California; farther E, N to Minnesota, Ontario, Quebec, Nova Scotia and Maine, two records from Bermuda, also vagrant to Hispaniola, Jamaica and Cayman Is. Many reports of vagrants are not acceptable owing to possibility of escaped cagebirds.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Classified as "Declining" in USA (Yellow WatchList priority species for conservation). Locally fairly common. Estimated global population c. 4,500,000 individuals. Some populations are shrinking, or have shrunk, at very significant rate, and overall general decline noted throughout range. Breeding Bird Survey data show statistically significant average decline of 3·2% annually (giving overall accumulated decline of 63·5%) during years 1966–1996 (based mainly on data from W populations in Texas and Oklahoma), this decline possibly slowing in more recent years; E population estimated to have declined 75% over same period. Declines probably attributable mainly to habitat loss, for example more aggressive suppression of brush along highway borders. The species appears unable to adapt to most golf courses, now a widespread potential habitat. For W populations, loss of riparian habitat in moult staging area is potentially damaging. Effect on E population of increased breeding range of Brown-headed Cowbirds is a further concern, although these populations appear to have retained or acquired some defence mechanisms against nest parasitism. Trapping for cagebird trade, both for domestic market and for export, still widespread in Mexico and Central America and may have significant effect on overall numbers. Recent studies in the Carolinas may indicate that decline there could be slowing.

(2004, 2010c), Beal *et al.* (1916), Brennan & Kuvlesky (2005), Butchart & Stattersfield (2004), Dhondt & Dhondt (2008), Fisk (1974), Forsythe (1974), Fuller (2010), Jones *et al.* (2005), Kopachena & Crist (2000a, 2000b), Land (1970), Lanyon & Thompson (1984, 1986), Lebbin *et al.* (2010), Lowther, Lanyon & Thompson (1999), (1999), McCarthy (2006), Monroe (1968), Parmalee (1959, 1964), Springborn & Meyers (2005), Sprunt (1968), Storer (1961), Strecker (1893), Taber (1968a), Taylor (1974), Taylor *et al.* (1989), Thompson, C.F. & Lanyon (1979), Thompson, C.W. (1991a, 1991b), Thompson, W.L. (1969, 1976), Whitehead *et al.* (2002).

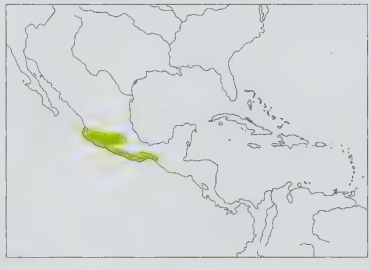
41. Rose-bellied Bunting

Passerina rositae

French: Passerin à ventre rose **German**: Rosenbauchfink **Spanish**: Azulillo Ventrirrosado
Other common names: Rosita/Rosita's Bunting

Taxonomy. *Cyanospiza rositae* Lawrence, 1874, Cacoprieto, Isthmus of Tehuantepec, Mexico.
Genus sometimes placed in family Emberizidae. Monotypic.
Distribution. E Oaxaca (W to c. 97° W) and W Chiapas (E to c. 93° W), in S Mexico.

Descriptive notes. 13·5–14·5 cm; 19·5–20·5 g (Chiapas). Male is bright electric-blue above, purplish-blue on crown, becoming brighter on lower back and rump; lores dark, white eyering broken in front and behind (giving two crescents); shoulder bright blue, primaries and secondaries greyish-black with broad blue edgings (giving overall blue appearance to closed wing); rectrices bright blue with black shafts; chin greyish-white, throat and chest blue, reddish-pink mottling on chest becoming salmon-pink on belly and vent; flanks blue; iris dark brown; bill blackish above, pale greyish-blue below; legs lead-grey. Female has head and upperparts greyish-brown, sometimes with hint of bluish, becoming bluish on rump; wing feathers dull brown, buff-brown edging is less contrasting than on similar congeneric females, rectrices grey with bluish on outer webs; face grey-brown, pale broken eyering; buffy brown or pinkish-buff below, becoming warmer on throat to lower breast and paler on lower belly; bare parts as for male. Immature male has crown dull grey-black, bright deep indigo-blue feathers growing through as moult progresses, back grey-brown with bright blue patches, uppertail-coverts bright blue, chin whitish, throat, chest and belly rose-coloured, lower belly yellowish-buff; immature female similar to adult, but generally duller, with only faint blue on uppertail-coverts and rump, underparts dusky buff. Voice. Song a sweet, slightly burry warble; call note a wet "plik" or "plek".



Habitat. Arid and semi-arid thorn-forest, denser parts of deciduous forest, also semi-humid deciduous gallery woodland, also swamp-forest; sometimes associated with pasture edge. At 180–800 m.
Food and Feeding. No information available on diet. Forages singly and in pairs. Occurs at lower to middle levels.
Breeding. Only two nests described, one with fresh eggs on 30th Jul and one with heavily incubated eggs on 29th Jun. Nest an open cup made from dead leaves, shredded bark and fine weed stems, lined with finer plant material, external diameter 10–12 cm, internal cup 4–5·5 cm, each in crotch of small sapling at height of 1·5 m and 4 m, respectively. Clutch 3 or 4 eggs, plain white or light bluish, spotted and blotched, especially at blunt end, with reddish-brown or lavender. No other information.
Movements. Largely sedentary; in some locations in Chiapas present in some months and less common or absent in others.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Isthmus of Tehuantepec EBA. Locally fairly common to common within its limited range. Global population estimated at fewer than 50,000 individuals. Possibly declining because of habitat degradation. Within overall indicated range, not all habitat is suitable for this species; for example, in La Sepultura Biosphere Reserve (Chiapas), less than 20% was found to be suitable. Notwithstanding its attractive plumage, does not appear to be threatened by trapping for cagebird trade.

42. Orange-breasted Bunting

Passerina leclancherii

French: Passerin arc-en-ciel **German**: Orangeblaufink **Spanish**: Azulillo Pechinaranja
Other common names: Leclancher's Bunting, Rainbow Bunting

Taxonomy. *Passerina leclancherii* Lafresnaye, 1840, Acapulco, Guerrero, Mexico.
Genus sometimes placed in family Emberizidae. This species reported as hybridizing with *P. cyanea* in captivity; reports of hybridization in wild apparently incorrect. Two subspecies recognized.
Subspecies and Distribution.
P. l. grandior Griscom, 1934 – W & SW Mexico from Colima, Michoacán and interior Guerrero E to S Puebla and S on Pacific slope of Oaxaca to SW Chiapas.
P. l. leclancherii Lafresnaye, 1840 – coastal C Guerrero, in SW Mexico.

Descriptive notes. 12·5 cm; 12–15·1 g. Male nominate race has crown bright apple-green, becoming bright turquoise-blue on nape and greener-tinged turquoise on upperparts; rump bright blue, shoulder bright blue, greater coverts and outer webs of flight-feathers dull blue-green with narrow bright blue fringes; rectrices dull blue with narrow paler bright blue edges; ear-coverts turquoise or light cerulean blue, eyering, lores and throat bright yellow, becoming richer and more orange on chest; belly and vent bright yellow; iris dark brown; bill blackish-grey above, greyer base below; legs greyish. Female is greenish-grey above, becoming more clear green on rump, more bluish uppertail-coverts and tail; eyering, lores and throat yellow, becoming more greyish-yellow or olive-yellow on chest and flanks; bare parts as for male. Immature male is similar to female, but brighter, with ear-coverts mostly turquoise, chest more orange, uppertail-coverts turquoise; immature female duller and greyer above than adult, duller yellow below, chest dusky yellow, little blue above; female (unlike that of congeners) exhibits delayed plumage maturation. Race *grandior* is identical to nominate in plumage, but significantly bigger. Voice. Song a sad, sweet warble, often slower and shorter than that of other members of genus. Call "chlik" or "tchik".
Habitat. Arid or semi-arid deciduous thorn-forest, field edges, scrubby pasture; in areas of high seasonality of rainfall. Sea-level to 1200 m, mostly below 900 m.
Food and Feeding. No published data on diet in the wild; captives will take apples, canary seed (*Phalaris canariensis*) and white millet seeds, ant pupae (Formicidae) and mealworms. Occurs in pairs and in small groups. Forages on or near ground, often along roadsides.
Breeding. Birds in breeding condition, mid-May to late May and in laying condition mid-Jun to late Jun; at higher altitudes, in breeding condition late Jul to early Aug. Nest a cup made from grasses, roots and dry leaves, lined with finer dry grasses, well hidden low down in bush or thick shrub. Clutch 3–4 eggs, bluish-white or greenish-white. No other information.
Movements. Largely resident. At certain locations in Chiapas present in some months and absent in others; e.g. in dry habitat present in Feb and absent Oct–Dec, while at more humid locations, not far distant, present in Jul–Aug and absent in May, Jun and Sept. One record in extreme S USA (S Texas), c. 1400 km N of normal breeding range, but possibility of captive origin cannot be totally excluded.
Status and Conservation. Not globally threatened. Fairly common in much of its range. In Chiapas, only a minor proportion of apparently suitable habitat is occupied by this species. Commonly caught as a cagebird; several hundred legally exported in 2000 and 2001, although this number diminished in 2002.

Class AVES

Order PASSERIFORMES

Suborder OSCINES

Family EMBERIZIDAE (BUNTINGS AND NEW WORLD SPARROWS)

- Tiny to medium-sized passerines with conical bill, many simply patterned in brown, black, grey, yellow and white, often streaked brown or grey, some more colourful and/or strikingly marked.
- 8·5–24 cm.

- Holarctic, Neotropical, Afrotropical and Oriental Regions.
- Open and semi-open habitats, especially grassland; also woodland and forest edge.
- 76 genera, 326 species, 887 taxa.
- 36 species threatened; at least 3 subspecies extinct since 1600.

Systematics

The buntings and the New World sparrows form a large assemblage of passerines with a geographical range that covers most of the world. They are absent only from the Australasian Region and Oceania. As currently constituted, the family Emberizidae contains more than 300 species, 326 in the present treatment, but it seems highly likely, on the basis of recent molecular-genetic research, that several genera do not really belong in this family.

Although the family has a wide distribution, the majority of its members, more than 80%, are found in the New World, and it is in this part of the world that most of the generic diversification has occurred. They are closely related to a larger group, commonly referred to collectively as the "New World nine-primaried oscine passerines", a not entirely accurate designation because some species are not exclusively New World taxa, and some other oscine groups that have only nine primary wing feathers are not placed in this group.

The New World nine-primaried oscines are generally divided into as many as seven families, and most of the species seem to fall within one or other of these. The families include the New World warblers (Parulidae), with 116 species; the tanagers (Thraupidae), containing 283 species in the present treatment; the cardinals (Cardinalidae) with 42 species; the New World blackbirds (Icteridae), containing 111 species; and the present family, Emberizidae, with more than 300 species. Some authors recognize Coerebidae, with the Bananaquit (*Coereba flaveola*) usually as its the sole member, and recently some separate the longspurs and snow buntings as the family Calcariidae, with a total of six species. In the present arrangement, the Bananaquit is included within the tanager family, while the longspurs and snow buntings are incorporated within Emberizidae. With the exception of Emberizidae (including Calcariidae), all of these families normally occur only in the New World. Collectively, they contain nearly 880 species, some 8% of the world total. The Olive Warbler (*Peucedramus taeniatus*), which has generally been accorded its own monotypic family, Peucedramidae, has sometimes been placed with the above families because it resembles a New World warbler, but it appears not to be closely allied to them. Indeed, molecular analysis carried out by K. A. Jønsson and J. Fjeldså suggested that *Peucedramus* is allied to the Eurasian accentors (Prunellidae).

Most authors now recognize five or six basic groups of taxa, the Bananaquit being probably best placed with the tanagers, rather than in a monotypic family. They differ, however, in their hierarchical classifications, some recognizing most or all of the aforementioned families as subfamilies within a greatly expanded Emberizidae. For example, E. C. Dickinson, in the revised and enlarged third edition of *The Howard and Moore Complete Checklist of the Birds of the World*, published in 2003, treats the groups as separate families, as also does the *AOU Check-list of North American birds*. C. E. Hellmayr, in the first half of the twentieth

The three longspur species in the genus Calcarius *are not closely related to other members of Emberizidae. Together with McCown's Longspur* (Rhynchophanes mccownii) *and the Snow Bunting* (Plectrophenax nivalis) *and McKay's Bunting* (P. hyperboreus), *they are sometimes placed in a new family, Calcariidae. Smith's Longspur* (Calcarius pictus) *and the* ***Chestnut-collared Longspur*** *are exclusively North American in their distribution, but the Lapland Longspur* (C. lapponicus) *breeds throughout the arctic and subarctic regions of North America, Europe and Asia. Longspurs are named after their elongated hind claw.*

[*Calcarius ornatus*, Saskatchewan, Canada. Photo: Glenn Bartley]

*The **Snow Bunting** is a large emberizid with a large conical bill and relatively short, notched tail. The wings are pointed and relatively long, which is typical of emberizids that migrate long distances or live in windy environments. The three* Calcarius *longspurs include two species with long, pointed wings and one with shorter and more rounded wings. Snow Buntings are sexually dimorphic both in their breeding plumage and in size, the female being smaller. Geographical variation in Snow Buntings is not well understood and is complicated by a high degree of individual variation.*

[*Plectrophenax nivalis nivalis*, Helsinki, Finland. Photo: Markus Varesvuo]

century, treated the cardinals, Darwin's finches of the Galapagos Islands, the cardueline finches, and the New World sparrows and buntings as subfamilies in the family Fringillidae, whereas C. G. Sibley and B. L. Monroe, in 1990, considered them to be distinct tribes within the subfamily Emberizinae. Shortly thereafter, S. Cramp and C. M. Perrins, in the *Handbook of the Birds of Europe, the Middle East* and *North Africa*, listed Parulidae, Thraupidae and Icteridae as three separate families, and split the Emberizidae into the subfamilies Emberizinae and Cardinalinae.

Although these basic groups are generally recognized by all taxonomists, there are many species that appear to be borderline cases. As a result, a relatively large number are considered to be *incertae sedis*, of uncertain position, this no doubt reflecting the close similarity among the species of nine-primaried oscines. As more information is gathered and more knowledge gained, especially through molecular biology, it is certain that substantial changes in the higher-level classification will continue to be made.

Over the past century, much information has been gathered by ornithologists with regard to the affinities of these nine-primaried oscines. Although explicit criteria for classification usually were not stated, traditional taxonomies were doubtless based on external morphology, especially bill configuration: buntings and New World sparrows generally have a conical bill that can be used for cracking and milling seeds. Characters associated with feeding, however, seem to be evolutionarily malleable, and subject to convergence. We have learnt that many species with bills that are well suited for seed-eating, or, for that matter, for nectarivory or fruit-eating, have apparently evolved independently in groups that are otherwise not particularly closely related; bill morphology alone, therefore, does not necessarily predict similarities based on other features. In other words, many bird species with a conical bill like that of a New World sparrow are not particularly closely related to the Emberizidae. Some studies have concentrated on various anatomical and physiological features. In particular, W. J. Beecher studied comparative jaw musculature; D. Mainardi, C. G. Sibley and W. Stallcup examined pelvic musculature and serology; J. Robins, G. Schnell, J. D. Rising, J. D. Webster and J. R. Webster undertook multivariate analyses of skeletal measurements; H. B. Tordoff investigated cranial and palatal characters; and R. Raikow studied appendicular myology.

All of this research has generally supported the recognition of the Emberizidae as a natural group which, if not monophyletic, is at least paraphyletic, but it has yielded few characteristics that have supported a constant classification.

Ongoing molecular analyses are contributing significantly to an understanding of the relationships among these nine-primaried oscine species. In 2006, for example, Jønsson and Fjeldså compared results from 99 different molecular analyses of sparrow-like birds and provided a useful summary. More recently, analyses of mitochondrial DNA by J. M. DaCosta and colleagues, added to earlier work, clarified the relationships of the species within the genera *Aimophila* and *Pipilo*, supporting the contention that these genera are, as delimited in earlier taxonomies, polyphyletic. Again, these studies corroborate the conclusions of the many ornithologists who had previously based their analyses on morphology, breeding biology, ecology and behaviour.

Modern molecular-genetic research has strongly indicated that several genera placed in the present family Emberizidae almost certainly do not belong there. The monotypic genus *Euneornis*, formerly placed in Coerebidae, a family no longer recognized, and currently included in Emberizidae, may well be closest to the tanagers in the family Thraupidae. Similarly, several other Caribbean genera, namely *Loxipasser*, *Melopyrrha*, *Loxigilla* and *Melanospiza*, are probably better included within Thraupidae, as also are the Galapagos genera *Certhidea*, *Platyspiza*, *Camarhynchus* and *Geospiza*. In fact, these modern molecular-genetic studies suggest that 19 other genera currently in Emberizidae are more closely related to members of the tanager family. These are the *Tiaris* grassquits, the high-Andean and Patagonian *Phrygilus* and *Diuca*, *Haplospiza*, the *Poospiza* mountain-finches of the high Andes, *Sicalis* yellow-finches, *Embernagra* pampa-finches, the monotypic grassquit genus *Volatinia*, the *Sporophila* seedeaters and *Oryzoborus* seed-finches, the *Catamenia* seedeaters of the high Andes, the Central American *Acanthidops*, the Argentine *Saltatricula*, the *Coryphospingus* and *Rhodospingus* finches, the *Paroaria* cardinals, and the three monotypic genera *Porphyrospiza*, *Charitospiza* and *Gubernatrix*.

The Snow Bunting (*Plectrophenax nivalis*) and the Lapland Longspur (*Calcarius lapponicus*) are Holarctic in distribution, but probably of New World origin. In North America there are two species of *Plectrophenax*, one of which, McKay's Bunting (*Plectrophenax hyperboreus*), breeds only on a few islands in the Bering Sea, and is perhaps better treated as a well-marked race of the Snow Bunting. Of the four species of longspur, only the Lapland Longspur has an Holarctic distribution, the other

All except four of the 35 Eurasian emberizid species are, at present, placed in the genus Emberiza. *The* ***Yellow-throated Bunting****'s permanently erect crest is unusual; most emberizids with a crest raise this only when excited or displaying. The* ***House Bunting*** *is more typical of* Emberiza *(and, with its rather plain plumage, easily confused with three other* Emberiza *species in its range), though smaller and slighter than many of its congeners.*

Right: *Emberiza sahari*, Oued Massa, Morocco. Photo: Mathias Schäf]

three being exclusively North American. The Lapland Longspur, until fairly recently considered an *Emberiza* in Europe, has a circumpolar distribution, breeding throughout arctic and subarctic regions; Smith's Longspur (*Calcarius pictus*) breeds in northern Canada and central Alaska, and McCown's Longspur (*Rhynchophanes mccownii*) and the Chestnut-collared Longspur (*Calcarius ornatus*) breed in the northern Great Plains. Molecular studies undertaken by R. Carson and G. Spicer, T. Yuri and D. Mindell, Jønsson and Fjeldså, J. Klicka and co-workers, and P. Alström and colleagues suggest that these six species are not closely related to other members of Emberizidae, and may, in fact, be basal to many of the other New World nine-primaried oscines. Some taxonomists nowadays place them in a new family, Calcariidae. While such treatment may prove to be preferable, the present treatment includes these "calcariid" genera in Emberizidae, as has been the traditional arrangement. Indeed, in terms of their biology and in various other aspects, they are very similar to the emberizids.

Of the 326 species in the Emberizidae as currently constituted, 35 are found in Eurasia. All except four of these are, at present, placed in the genus *Emberiza*. The exceptions are the Lapland Longspur and Snow Bunting, both found across the Holarctic; the Crested Bunting (*Melophus lathami*), resident in southern Asia from the Indian Subcontinent eastwards to south-east China; and the Slaty Bunting (*Latoucheornis siemsseni*), restricted to central and eastern China. The Corn Bunting (*Emberiza calandra*) of Europe and western Asia was for a while generally placed in the monotypic genus *Miliaria*, but in recent years it has been returned to *Emberiza*, in which it had previously been included.

All nine African members of the family are included in the genus *Emberiza*. In the South Atlantic, the Gough Finch (*Rowettia goughensis*) is confined to the island of that name in the Tristan da Cunha group, and the three species of *Nesospiza* are likewise found only in that group of islands, the Inaccessible Finch (*Nesospiza acunhae*), the Nightingale Finch (*Nesospiza questi*) and Wilkins's Finch (*Nesospiza wilkinsi*) being restricted to, respectively, Inaccessible Island, Nightingale Island and some of its offshore islets, and Nightingale Island alone; the three are sometimes treated as conspecific. All of these Tristan species are probably derived from South American emberizids. The Gough Finch, for example, closely resembles the Canary-winged Finch (*Melanodera melanodera*) of the Falkland Islands, and there are strong prevailing westerly winds at that latitude. The genus *Emberiza* is not represented in the Americas, except in the form of rare migrants and vagrants from the north-east Palearctic Region. No species of Emberizidae is native to the Australasian Region.

The sparrows inhabiting the northern temperate region of America have often been divided into two general groups, the grassland sparrows and the brushland sparrows. This separation, while based on ecological and behavioural characteristics, seems also, in general, to separate groups of closely related species, although several genera are not easily placed in either category. The grassland clade has been thought to include *Passerculus*, *Ammodramus* and, perhaps, *Xenospiza*. Of these, *Passerculus*, the savannah-sparrow complex, has often been subsumed in *Ammodramus*, but molecular data do not support this treatment. Similarly, the monotypic *Xenospiza*, containing the Sierra Madre Sparrow (*Xenospiza baileyi*), has been placed in *Ammodramus*, but this has been questioned for several reasons. F. A. Pitelka, for example, argued that the similarities of *Xenospiza* to *Ammodramus* were superficial, and that, in general size and proportions, the Sierra Madre Sparrow was more like Lincoln's Sparrow (*Melospiza lincolnii*). Klicka and G. M. Spellman's molecular data separate *Ammodramus* into two groups, a grassland group and a marshland group. The former included the savannah-sparrow complex, currently in *Passerculus*, and Baird's Sparrow (*Ammodramus bairdii*), the Grasshopper Sparrow (*Ammodramus savannarum*), the Grassland Sparrow (*Ammodramus humeralis*) and the Yellow-browed Sparrow (*Ammodramus aurifrons*). The marshland group incorporated the Seaside (*Ammodramus maritimus*), Nelson's (*Ammodramus nelsoni*), Saltmarsh (*Ammodramus caudacutus*), Le Conte's (*Ammodramus leconteii*) and Henslow's Sparrows (*Ammodramus henslowii*), and perhaps also the Sierra Madre Sparrow. Robins and Schnell's multivariate analysis of 48 skeletal characters of selected species of grassland sparrow more or less supports this separation, placing the Grassland, Grasshopper and Baird's Sparrows and the savannah-sparrow complex in one group, and Le Conte's, Saltmarsh and Seaside Sparrows in another; *Xenospiza* is in the former group, but does not cluster closely with it, and Henslow's Sparrow is with the latter, but again is not closely clustered with it. Within the grassland assemblage, the Grassland Sparrow and the Yellow-

The "Fox Sparrow" was formerly treated as a single, highly variable species. The 18 recognized races were divided into four groups according to plumage, bill morphology and breeding distribution: red (iliaca), *sooty* (unalaschcensis), *thick-billed* (megarhyncha) *and slate-colored* (schistacea). *Mitochondrial DNA analysis provided support for the four groups to be recognized as species, which is the treatment followed here. The race* zaboria *of the* ***Red Fox-sparrow*** *(shown here) is more faintly streaked than the nominate, but plumage varies gradually over distance, and many individuals cannot safely be assigned to either race.*

[*Passerella iliaca zaboria*, British Columbia, Canada. Photo: Glenn Bartley]

browed Sparrow occur only in South America, and have sometimes been put into a separate genus, *Myospiza*.

From recent molecular studies, including that by Klicka and Spellman, and others, it appears that Henslow's Sparrow and Baird's Sparrow are sister-species, and Le Conte's Sparrow, the Saltmarsh Sparrow, Nelson's Sparrow and the Seaside Sparrow form a monophyletic clade. Traditionally, the savannah-sparrow complex, the Grassland Sparrow and the Yellow-browed Sparrow have been thought to be closely related to Henslow's and Baird's Sparrows, but the molecular data available do not support this. Klicka and Spellman, however, found that the Sierra Madre Sparrow clusters with the three species of *Melospiza*, namely the Swamp Sparrow (*Melospiza georgiana*), Lincoln's Sparrow and the Song Sparrow (*Melospiza melodia*), which have traditionally been placed with the brushland sparrows, and these, in turn, cluster with Henslow's Sparrow, Baird's Sparrow and the savannah-sparrow complex. Their analyses also support the placement of the Vesper Sparrow (*Pooecetes gramineus*) and Bell's Sparrow

Recent molecular-genetic studies suggest that the genus Junco *spread quickly north from Central America in the post-glacial period. The farther south in Central America, the older is the lineage. The southernmost, and the largest of the three species, is the monotypic* ***Volcano Junco****. Its closest relative is the southern race* alticola *of the Yellow-eyed Junco* (Junco phaeonotus). *Northern populations of Yellow-eyed Junco are, in turn, very close genetically and morphologically to southern races of the Dark-eyed Junco* (J. hyemalis). *The 16 races of the Dark-eyed Junco vary in size, plumage and bill colour and form six groups, which are sometimes treated as six separate species.*

[*Junco vulcani*, Irazú Volcano National Park, Costa Rica. Photo: Boris Nikolov]

The sparrows inhabiting the northern temperate region of America have often been divided into two general groups, the grassland sparrows, to which Ammodramus *belongs, and the brushland sparrows. Molecular data have been used to separate* Ammodramus *into two further groups, a grassland group and a marshland group, the latter containing the* ***Seaside Sparrow*** *along with Nelson's* (Ammodramus nelsoni), *Saltmarsh* (A. caudacutus), *Le Conte's* (A. leconteii) *and Henslow's Sparrows* (A. henslowii). *Seven extant races of Seaside Sparrow are recognized. Two races, including the very distinctive "Dusky Seaside Sparrow"* (nigrescens), *are extinct.*

(*Artemisiospiza belli*), but not the Black-throated Sparrow (*Amphispiza bilineata*), and the monotypic Striped Sparrow (*Oriturus superciliosus*) appears to belong in this group. Recent work shows that the Five-striped Sparrow (*Amphispiza quinquestriata*), formerly included in the genus *Aimophila*, is best placed in *Amphispiza*, close to the Black-throated Sparrow.

What was formerly a large genus, *Aimophila*, has recently been split into several smaller genera. Its greatest species richness was in Mexico and Central America, a few species reaching the southern USA, and with two found only in South America. Research by L. Wolf, however, indicated that *Aimophila* was not monophyletic, and that its species should be separated into three or four groups that probably have separate evolutionary histories and are not particularly closely related to each other. This has recently been supported by the genetic work of DaCosta and co-workers, and their results have been widely accepted by the ornithological community. Two groups of species are now placed in the genus *Peucaea:* the Cinnamon-tailed (*Peucaea sumichrasti*), Rufous-winged (*Peucaea carpalis*), Stripe-headed (*Peucaea ruficauda*), Black-chested (*Peucaea humeralis*) and Bridled Sparrows (*Peucaea mystacalis*); and Cassin's (*Peucaea cassinii*), Bachman's (*Peucaea aestivalis*) and Botteri's Sparrows (*Peucaea botterii*). These all occur in grassland, often xeric, and among xeric shrubs, and in pine (*Pinus*) savanna in Mexico and the southern USA. The first group, the Cinnamon-tailed, Rufous-winged, Stripe-headed, Black-chested and Bridled Sparrows, probably radiated in the lowland thorn-forests of Mexico and the Pacific lowlands of Central America. The third group contains the Rufous-crowned (*Aimophila ruficeps*), Rusty (*Aimophila rufescens*) and Oaxaca Sparrows (*Aimophila notosticta*), which appear to have radiated in the pine–oak (*Pinus–Quercus*) woodlands of Mexico and Central America; these remain in the genus *Aimophila*, the type species of which is *Aimophila rufescens*. As mentioned above, the Five-striped Sparrow, often placed in *Aimophila*, is now included with the Black-throated Sparrow in *Amphispiza*, and this genus appears to be closely allied to *Chondestes* and *Calamospiza*.

Recent genetic data published by DaCosta and colleagues showed that the relationships among some of the North American genera were not properly reflected in the linear sequence of earlier lists. For example, the towhee genus *Pipilo* was diphyletic. Four species, the Collared (*Pipilo ocai*), Green-tailed (*Pipilo chlorurus*), Spotted (*Pipilo maculatus*) and Eastern Towhees (*Pipilo erythrophthalmus*), should follow *Atlapetes* in the sequence, with the three *Aimophila* species, the Rufous-crowned, Rusty and Oaxaca Sparrows, coming next. The four species of "brown towhee", namely the Canyon (*Pyrgisoma fuscum*), White-throated (*Pyrgisoma albicolle*), California (*Pyrgisoma crissale*) and Abert's Towhees (*Pyrgisoma aberti*), are now placed in the

In keeping with their largely terrestrial lifestyles, the New World sparrows are generally brownish or rusty in colour. Many, including the ***Lark Sparrow****, have a boldly marked head pattern. The tail pattern of the Lark Sparrow is also very distinctive, the outermost pair of rectrices being edged with white, and the other outer rectrices boldly white-tipped. The sexes are similar in coloration, although the female is somewhat smaller. The Lark Sparrow occupies the monotypic genus* Chondestes. *It appears closest to the Lark Bunting* (Calamospiza melanocorys) *and the Five-striped* (Amphispiza quinquestriata) *and Black-throated Sparrows* (A. bilineata).

genus *Pyrgisoma* along with the Rusty-crowned Ground-sparrow (*Pyrgisoma kieneri*), which was formerly placed with the two other ground-sparrows in the genus *Melozone*. The summary analyses of Jønsson and Fjeldså suggest that the *Chlorospingus* bush-tanagers, conventionally classified with the tanagers in Thraupidae, belong in this group.

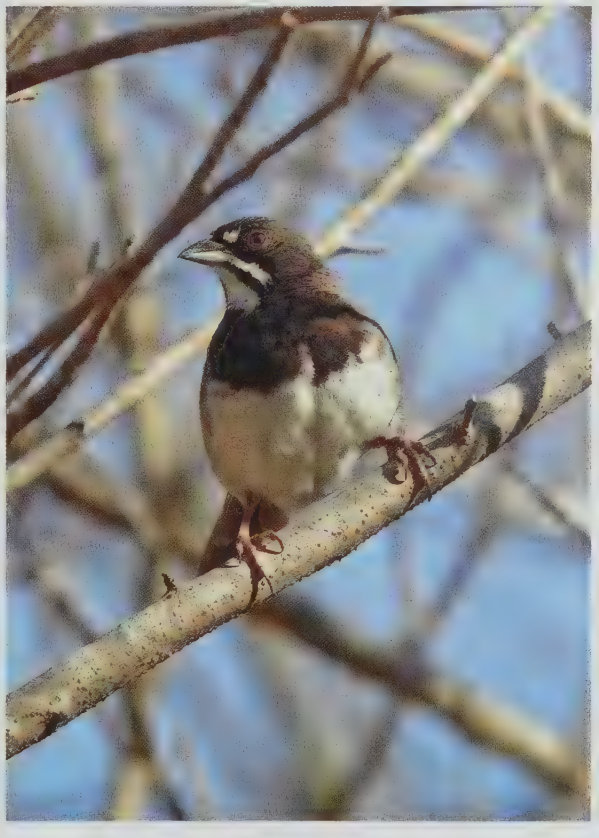
The grassquits in the genera *Volatinia* and *Tiaris*, the seedeaters in *Sporophila*, the seed-finches in *Oryzoborus*, the grass-finches in *Emberizoides*, and their allies form a widespread and diverse group of small, seed-eating Neotropical nine-primaried oscines. Although they have often been included within Emberizidae, Sibley and Monroe placed them with the tanagers in Thraupidae, and this treatment is supported by the molecular-genetic studies of Jønsson and Fjeldså. The Caribbean bullfinches (*Loxigilla*, *Melopyrrha*), the Yellow-shouldered Grassquit (*Loxipasser anoxanthus*), the Orangequit (*Euneornis campestris*) and the St Lucia Black Finch (*Melanospiza richardsoni*) are part of this group, as probably are the Galapagos finches in the genera *Geospiza* and *Camarhynchus*. These molecular data also indicate that the South American cardinals (*Paroaria*), flowerpiercers (*Diglossa*), sierra-finches (*Phrygilus*) and warbling-finches (*Poospiza*) should all be placed in the tanager family.

Unsurprisingly, a number of taxonomic problems at the species level remain to be resolved. For example, in the genus *Sporophila*, the second largest in the family after *Emberiza*, some authors recognize a species *Sporophila melanops*, given the English vernacular name of the "Hooded Seedeater". Indeed, this is even listed "officially" as a Critically Endangered emberizid. It is known only from a single specimen, an adult male taken in October 1823 on the western border of Goiás, in Brazil; the precise locality was a lake 15 km north of Registro do Araguaia, on the east bank of the Araguaia River. This seedeater has not been found again, even with the advantages of modern technology and methods. Searches carried out along the floodplain of the Araguaia, most recently in December 2008 and January 2009 and, again, in July 2010, failed to produce any sightings. Although the Hooded Seedeater is included in a number of checklists and other authoritative works, it is considered likely that it was, in fact, a variant of the Yellow-bellied Seedeater (*Sporophila nigricollis*) or perhaps a hybrid between it and another member of this genus. Another seedeater of uncertain standing is the "Tumaco Seedeater", described as *Sporophila insulata* and known only from the island of Tumaco, a short distance off the coast of the south-west Colombian province of Nariño. It has a rufous rump and rufous underparts, but is otherwise more or less identical to the Chestnut-throated Seedeater (*Sporophila telasco*), which is resident on the Pacific coast and coastal slope from south-west Colombia southwards through the coastal lowlands to the desert valleys of northernmost Chile. The Tumaco population, which may well be extinct, is thought to be a subspecies or a variant of the Chestnut-throated Seedeater or, perhaps less likely, a hybrid between the latter and the Ruddy-breasted Seedeater (*Sporophila minuta*).

A further example from this problematic genus involves the form described as *Sporophila zelichi*, known as "Narosky's Seedeater" or the "Entre Ríos Seedeater", the latter name denoting the region of north-east Argentina from where the bird was initially described, in 1977. Narosky's Seedeater is still poorly known. It differs from the Marsh Seedeater (*Sporophila palustris*) only in its possession of a broad white nuchal collar, and is indistinguishable from the latter in its vocalizations and habitat choice; the two can even be found at the same localities. The form "*zelichi*" is considered to be a white-necked morph of the Marsh Seedeater or just possibly a hybrid between it and the Chestnut Seedeater (*Sporophila cinnamomea*).

Hybridization is probably not uncommon among the emberizids. Indeed, the Yellowhammer (*Emberiza citrinella*) and the Pine Bunting (*Emberiza leucocephalos*) regularly interbreed in a fairly extensive area of western and central Siberia, and there are many examples of occasional hybridization involving other members of the family. Among Darwin's finches in the Galapagos Islands, the Medium Ground-finch (*Geospiza fortis*) interbreeds rarely with the Small Ground-finch (*Geospiza fuliginosa*), and the resultant hybrids tend to have low fitness. On the island of

Until recently, the ***Sage Sparrow*** *and Bell's Sparrow* (Artemisiospiza belli) *were placed in the "brushland" sparrow genus* Amphispiza, *but recent molecular work indicates that the two are, instead, members of a well-resolved clade of "grassland" sparrows. They are, however, found in sagebrush, chaparral and other scrub habitats. Bell's and Sage Sparrows were formerly considered conspecific, the Sage Sparrow differing mainly in its larger size, paler coloration and more obvious streaking above. The race* canescens *of Bell's Sparrow, which is very similar to the Sage Sparrow and possibly hybridizes with it where the ranges meet, may be a separate species.*



[*Artemisiospiza nevadensis nevadensis*, Mono County, California, USA. Photo: Brian E. Small]

Daphne Mayor, however, following the 1982–1983 El Niño event and the accompanying huge rainfall, these smaller-billed hybrids had elevated fitness as a result of the subsequent superabundance of small seeds on the island (see also Morphological Aspects). Similarly, hybridization between the Medium Ground-finch and the Common Cactus-finch (*Geospiza scandens*) is rare and hybrids have low fitness, but the latter's fitness was again greater after the El Niño event. It is thought that large-scale hybridiza-

The ***Black-chested Sparrow*** *is a restricted-range species from Mexico. Two of its closest relatives are also Mexican endemics with restricted ranges. The* Peucaea *species were formerly included in* Aimophila, *a large genus of mostly Mexican and Central American sparrows of arid tropical scrub-forest and thorn-forest habitats. The* Aimophila *species were morphologically and vocally diverse, and held by many to constitute an "unnatural assemblage". Genetic data subsequently indicated that* Aimophila *included four distinct lineages. The resurrected genus* Peucaea *includes eight species.*

[*Peucaea humeralis astica*, Colima, Mexico. Photo: Pete Morris]

The Neotropical sparrow genus Arremon *includes more than 20 medium-sized, robustly built, predominantly greenish and relatively colourful species. The* ***Golden-winged Sparrow*** *is a stocky and pot-bellied, long-billed and short-tailed sparrow, one of a group of five similar species that may form a superspecies. Two former genera,* Lysurus *and* Buarremon, *were merged with* Arremon *in 2008. The eight taxa forming the "White-browed Brush-finch complex" (formerly* Buarremon torquatus*) were subsequently proposed as representing eight distinct species, a treatment followed here.*

[*Arremon schlegeli schlegeli*, Santa Marta, Colombia. Photo: Pete Morris]

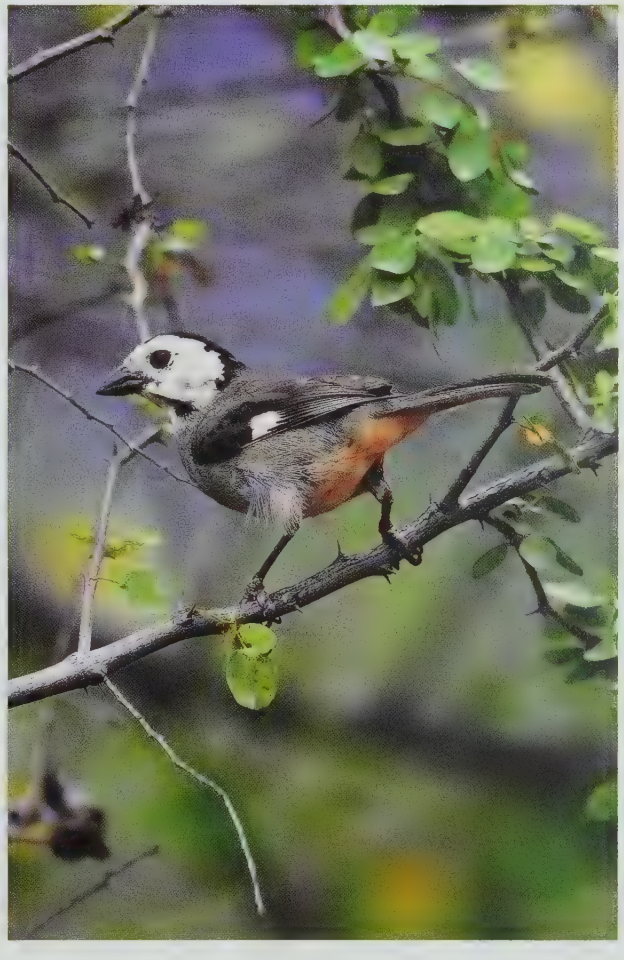
tion between the Medium Ground-finch and the Large Ground-finch (*Geospiza magnirostris*) has occurred on Santa Cruz, where the former species is noticeably larger-billed than are its populations on other islands in the archipelago.

Several intriguing taxonomic problems require full investigation. As just one example, in Argentina, a form of yellow-finch breeding in the Sierra de la Ventana, in Buenos Aires, was originally identified as the Patagonian Yellow-finch (*Sicalis lebruni*), but it was then reidentified as an isolated form of the Greater Yellow-finch (*Sicalis auriventris*). However, quite apart from its notable geographical separation from the otherwise known ranges of both of these species, the big problem is that its nesting behaviour is quite different from both of theirs. Its cup-nest, built from dry grasses and with a finer lining, is placed approximately 36 cm up in tussock paspalum grass (*Paspalum quadrifarium*); in this it lays four whitish eggs, with darker markings concentrated at the wide end, which it incubates for twelve days, and the young take at least ten days to fledge. The nest-site is very different from those of both of the species in which it has been tentatively placed, and clutch size and egg coloration are also different from those of the Greater Yellow-finch. It could be that an as-yet-undescribed species is involved.

Morphological Aspects

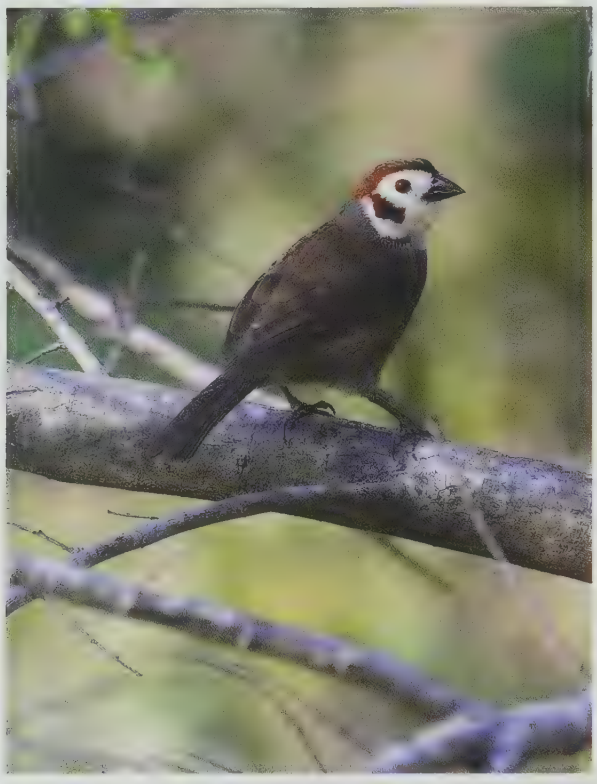
Buntings and New World sparrows are tiny to medium-sized songbirds, ranging in mass from about 6 g to almost 70 g, and in length from about 8·5 cm to 25 cm. As a group, the smallest emberizids are the grassquits and seedeaters, 6–15·5 g in weight and 8·5–12 cm in length. The Yellow-bellied Seedeater, for instance, has a length of 8·5–10·3 cm and weighs 8·5–11·2 g, the Ruddy-breasted Seedeater measures 8·6–9·6 cm and weighs 7–9 g, and the corresponding figures for the Blue-black Grassquit (*Volatinia jacarina*) are 8·7–10·9 cm and 8–12 g. Sparrows in the genus *Spizella* are among the smallest of the New World sparrows, generally being 10–15 g in weight and 11–14 cm in length. The largest of the sparrows are the towhees: the California Towhee is 21–24 cm in length and weighs about 33–67 g. Weight data are, of course, of limited value in expressing size, because many individuals, prior to migration, deposit large quantities of fat, sometimes even doubling their usual body mass. In addition, the body mass of a females during the laying period varies considerably and on a daily basis.

Many species exhibit geographical variation in size. Song Sparrows, for example, provide a striking example of this. Wing lengths of males of the subspecies *maxima* and *sanaka*, from the Aleutian Islands, in Alaska, range from 82 mm to 87 mm, females being slightly smaller, 78–85 mm, whereas, at the other



The ground-foraging ***Large-footed Finch*** *uses its large feet and powerful legs to scratch in soil and leaf litter. The simultaneous use of both feet, bilateral or double scratching, is widespread among the Emberizidae, but especially well developed in this species. The Large-footed Finch is the only species in the genus* Pezopetes, *but is sometimes included in the brush-finch genus* Atlapetes. *It typically lays only one egg, which is unusual for the family in general and for mainland emberizids in particular.*

[*Pezopetes capitalis*, San Gerardo, Costa Rica. Photo: Theodoulos Poullis]



The brush-finches of the genus Atlapetes *have their greatest diversity in the Andes. Forms with different colours may replace each other sharply at different altitudes on the same slopes, or in similar habitats on different slopes. In older classifications, grey species such as the* ***Slaty Brush-finch*** *and yellow-and-green species such as the* ***Bolivian Brush-finch*** *were placed in different groups, and similarly coloured populations replacing each other in corresponding ecological zones on different slopes were ranked as subspecies of the same species. Mitochondrial DNA sequence data indicate that traditional groupings based on plumage colours did not follow evolutionary trajectories in the genus, and also that many forms currently ranked as subspecies are genetically more divergent than sympatric species. The restricted-range* ***Santa Marta Brush-finch*** *is the only* Atlapetes *species in the Santa Marta Mountains of Colombia, but the Tumbesian endemic* ***White-winged Brush-finch*** *is found in mixed flocks with other brush-finches.*

extreme, males of the subspecies *samuelis*, from San Francisco Bay, in California, range from 56 mm to 64 mm and females from 56 mm to 60 mm.

Individuals living on islands commonly have a larger average body size than those from nearby mainland populations. For example, Savannah Sparrows (*Passerculus sandwichensis*) of the subspecies *princeps*, from Sable Island, in Nova Scotia, have wing lengths of 73·3–83·4 mm, whereas those from Kuujjuaq, in north mainland Quebec, have wing lengths of 66·9–72·7 mm. Similarly, Savannah Sparrows from Umnak Island, in the Aleutian Islands, have wing lengths measuring 73·4–78·3 mm, whereas those from Wasilla, on the Alaskan mainland, range from 68·8 mm to 76·8 mm.

Wing shape varies both among species and, geographically, within species. Generally, individuals that migrate long distances, or live in windy environments, have relatively pointed wings, as illustrated by, among others, the longspurs and the snow buntings, whereas those that are resident or migrate only short distances have more rounded wings. Within the genus *Calcarius*, the Lapland and Smith's Longspurs, which breed in the north and, in North America, winter in the southern Great Plains, have pointed wings, whereas the Chestnut-collared Longspur, which breeds in the prairies of southern Canada and the northern USA and winters in the southern Plains and northern Mexico, has shorter and more rounded wings. McCown's Longspur, in the monotypic genus *Rhynchophanes*, which has a range similar to that of the Chestnut-collared Longspur, has a wing shape intermediate between the extremes found in *Calcarius*.

Emberizids have twelve rectrices. There is some variation in the tail shape, but most species have a rather short tail that is either rounded or slightly notched, but not forked. Some members of the family, such as Le Conte's, Grasshopper, Nelson's and Saltmarsh Sparrows, have a short tail with pointed rectrices, this group hence being known collectively as "sharp-tailed sparrows". Towhees, on the other hand, have a long tail with more evenly round-ended rectrices.

Bill shape is variable, both among and within species, but emberizids generally have a bill that is conical in shape and appears to be adapted to foraging for seeds, which these species, indeed, commonly do. The upper and lower mandibles of most of the species are sharply angled downwards at the base, this being especially marked in the Old World genus *Emberiza*; corresponding with a variably developed protuberance at the base of the horny palate is a recess in the lower mandible, which, towards the base, is often much deeper than the upper mandible. Rictal bristles are generally lacking, although some species have a few. The *Atlapetes* brush-finches have a medium-sized to rather

The genus Melozone *includes two large ground-feeding sparrows with dull olive upperparts, paler underparts and a striking head pattern.* ***Prevost's Ground-sparrow*** *was formerly considered close to, and sometimes conspecific with, the Rusty-crowned Ground-sparrow* (Pyrgisoma kieneri), *but differs in both adult and juvenile plumages. The second member of* Melozone, *the White-eared Ground-sparrow* (Melozone leucotis), *is a big sparrow with large feet and much black on its head and foreparts. The Costa Rican race* cabanisi *of Prevost's Ground-sparrow is sometimes considered to be a separate species.*

[*Melozone biarcuata hartwegi*, Mapastepec, Chiapas, Mexico. Photo: Nick Athanas]

The ***Rusty-crowned Ground-sparrow*** *was formerly included with the ground-sparrows in* Melozone, *but has been returned to the recently resurrected genus* Pyrgisoma. *Following a review of the towhee genus* Pipilo, *the towhees have been split and the four "brown towhee" species, the Canyon* (Pyrgisoma fuscum), *White-throated* (P. albicolle), *California* (P. crissale) *and Abert's Towhees* (P. aberti), *have also been moved to* Pyrgisoma, *reflecting the close relationship between these species and the Rusty-crowned Ground-sparrow.*

[*Pyrgisoma kieneri kieneri*, Durango Highway, Mexico. Photo: Pete Morris]

DNA-sequencing of Phrygilus *sierra-finches found evidence that the genus comprises four distantly related clades, with at least nine other genera between them. The four clades correspond to groups previously established mainly on the basis of plumage characters. Studies suggest that the* ***Mourning Sierra-finch*** *and the Carbonated Sierra-finch* (Phrygilus carbonarius) *should be in a separate genus. The* ***Black-hooded Sierra-finch*** *is one of four "hooded group" species; their nearest relatives may be* Sicalis *yellow-finches.*

[Left: *Phrygilus fruticeti fruticeti*, Chubut, Argentina. Photo: Darío Podestá.

Right: *Phrygilus atriceps*, Lauca National Park, Parinacota, Chile. Photo: Alejandro Torés]

long bill, in most cases with a distinctly curved culmen, while the somewhat longer conical bill of the *Phrygilus* sierra-finches is similar but usually more pointed and less curved. The Barbados Bullfinch (*Loxigilla barbadensis*) has a relatively short and rounded bill, and it is this bill shape that gave the four Caribbean species in this genus their English name of "bullfinch". The fringillid finches bearing that name have a similarly shaped bill, but the two are not in any way related. The bill of the Barbados Bullfinch is slightly longer than it is deep, and the upper mandible is often slightly longer than the lower mandible.

In an interesting study of adaptive diversification, A. Herrel and colleagues examined the functional consequences of variation in the size and shape of the bill of Darwin's finches in the genera *Certhidea*, *Platyspiza*, *Camarhynchus* and *Geospiza*. It was found that the sexes differed in head shape and in "bite force", the pressure exerted by the closing of the mandibles, females having a longer bill than that of the males in any given size class. Significantly, there were clear differences in the morphology of the bill and the head, these correlating with different feeding methods. Those species which crushed items at the base of the bill had a greater bite force, even at the tip of the bill, than those which used the bill tip to crush items or used probing as a means of foraging. The shape of the bill of "base-crushers" and that of "tip-biters" appeared to confer certain mechanical advantages by minimizing stress at the bill base and the bill tip, respectively, thereby reducing the risk of potential fracture. The researchers' findings corroborated the theory that bill shape is adaptive, and that it evolves through mechanical optimization through natural selection on feeding method.

It is instructive to consider the differences in bill shape and bill size of the ground-finches in the Galapagos genus *Geospiza*. The Small Ground-finch is widely sympatric with the Medium and Large Ground-finches, but there are no plumage features by which the three species can be reliably distinguished from one another. They do, however, differ in body size and bill structure, as well as in voice. The bill of the Medium Ground-finch is intermediate between those of the other two species, and, unlike that of the Large Ground-Finch, is always longer than it is deep. The small Ground-finch has a less powerful-looking bill which is thinner and narrower, and, because the culmen is shorter and straighter, it looks more triangular and pointed than the bill of the Medium Ground-finch. Another member of the genus, the Sharp-beaked Ground-finch (*Geospiza difficilis*) can occur alongside the Small Ground-finch in the higher parts of the Galapagos islands of Fernandina, Pinta and Santiago; as its vernacular name implies, however, the bill of the Sharp-beaked Ground-finch is noticeably longer and more pointed than that of its otherwise similar-looking relative.

An intriguing example of evolution in action was recorded on the island of Daphne Mayor, in the central Galapagos Archipelago, in the 1980s. The Medium Ground-finch is a generalist forager, and changes its diet according to the availability of suitable items. After the big rains produced in 1982–1983 by an El Niño event, small seeds became abundant on the island, where large seeds became rare. Consequently, individuals with a larger and wider bill, suited to feeding on large seeds, became far less numerous, and the population of the Medium Ground-finch on Daphne Mayor exhibited a reduction in mean bill size, brought about by natural selection for individuals which could forage more efficiently on smaller seeds (see also Systematics).

Most emberizids exhibit little sexual dimorphism in size, the males being slightly larger, by about 5%, than the females, as evidenced by, for example, the data on Song Sparrows (see above). There are, however, some exceptions. Male Corn Buntings are substantially larger than females of the species: males of the nominate race in Europe have an average wing length of 101·4 mm and a wing-length range of 96 mm to 107 mm, whereas the average for females is 92·8 mm and the range is 87–98 mm.

Many of the emberizids are sexually dimorphic in colour. Commonly, females are much like the males in general pattern, but are less brightly coloured. This is true, for instance, for most of the Old World species, the *Emberiza* buntings, though not the Corn Bunting, the sexes of which are virtually identical in plumage. The *Volatinia* and *Tiaris* grassquits, the seedeaters, the seed-finches and related species of Central and South America are dimorphic, and many also quite geographically variable in colour, as are the longspurs, the two snow buntings, the Lark Bunting (*Calamospiza melanocorys*) of the American Great Plains, and some of the towhees, such as the Eastern and Spotted Towhees, but not others, such as the Green-tailed, Canyon and Abert's Towhees. Most American sparrows are monomorphic in colour, although some, including the Black-chinned Sparrow (*Spizella atrogularis*) and the juncos (*Junco*), display slight colour dimorphism. The South American sierra-finches, warbling-finches and others are sexually dimorphic, whereas the sexes of the Inca-finches (*Incaspiza*) are similar in colour.

*The **Long-tailed Reed-finch** occupies the monotypic genus* Donacospiza, *but its song and colour pattern suggest that it may be closely related to the* Poospiza *warbling-finches. This species and the Black-and-rufous Warbling-finch* (Poospiza nigrorufa) *are reported as responding to one another's songs. A small, slim finch with short, rounded wings, the Long-tailed Reed-finch has pointed tail feathers, with the inner two pairs longer than the outer rectrices. The ends of these feathers may be frayed to even narrower points.*

[*Donacospiza albifrons*, Corrientes, Argentina. Photo: Darío Podestá]

In keeping with their largely terrestrial and near-terrestrial lifestyle, the New World sparrows are generally brownish or rusty in colour, although some, such as the Spotted and Eastern Towhees, the Lark Bunting and the longspurs, may be boldly patterned with black, white and chestnut, while the male of McKay's Bunting is mostly white. Many, such as several *Zonotrichia* sparrows, the Lark Sparrow (*Chondestes grammacus*), the two *Amphispiza* sparrows, and the Sage Sparrow (*Artemisiospiza nevadensis*) and Bell's Sparrow, have a boldly marked head pattern. Most of the Eurasian species likewise are predominantly brownish, but many also have rich rufous or chestnut colours, and also yellow; males of the Yellowhammer are mostly yellow in coloration, with some admixed rufous, especially on the rump. Many of the Middle and South American taxa, such as *Arremonops* and *Arremon*, are predominantly greenish, as is the Green-tailed Towhee, often

*The **White-winged Diuca-finch** was previously thought to form a superspecies with the Common Diuca-finch* (Diuca diuca). *But aspects of morphology and voice and the fact that the White-winged Diuca-finch hops, rather than walking as the Common Diuca-finch does, suggest that the two are not close. The White-winged Diuca-finch may be closest to the grey-and-white group of sierra-finches, the White-throated* (Phrygilus erythronotus) *and Red-backed Sierra-finches* (P. dorsalis). *It possibly breeds at a higher elevation than any other passerine in the Americas; nesting has been recorded at up to 5400 m. It will roost in crevasses within glaciers.*

[*Diuca speculifera magnirostris*, Cordillera Blanca, Peru. Photo: Cyril Ruoso/Bios]

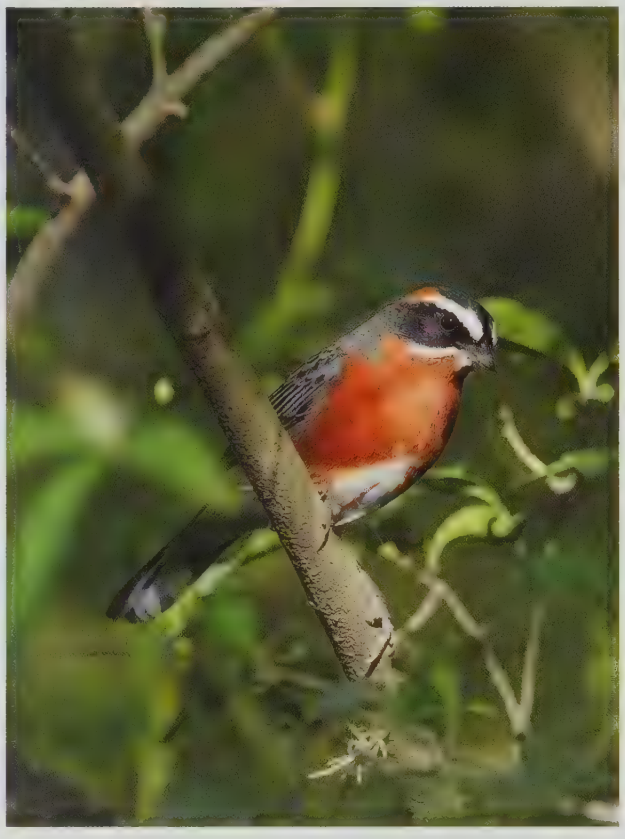
with rusty, black or white markings on the head, and many of the seedeaters and grassquits also are brightly coloured. Seedeaters can be quite variable, both within species and among species, being mostly black, or a varying mixture of black, cinnamon, grey and rusty. The sierra-finches and others, such as the Short-tailed Finch (*Idiopsar brachyurus*), some *Atlapetes*, *Junco* and *Diuca*, are predominantly grey, as are the Grey Bunting (*Emberiza variabilis*) and Slaty Bunting of the Palearctic. Many species possess a small crest. Some of these, including the Crested Bunting and the Yellow-throated Bunting (*Emberiza elegans*), have a permanently erect crest, but more commonly the crest is raised only when the bird is excited or is displaying.

The Slate-colored Seedeater (*Sporophila schistacea*) presents an intriguing example of apparent polymorphism. In a study of the species extending over a period of more than ten years, R. Restall found that both sexes had three discrete plumage phases, which he termed, respectively, the juvenile plumage, the intermediate plumage and the adult plumage. The female proceeded through each stage to adult plumage in a predictable manner, and exhibited comparatively little variation in appearance. The males, on the other hand, became increasingly variable in plumage as they became older, and the adults varied from being grey and white, which is the typical adult plumage of the male of this species, to being almost entirely blackish or dark grey, or being very pale, or being brownish and pale yellow, and with variable white markings or almost none at all. Restall illustrated eight different morphs, but stated that up to as many as 20 have been identified in northern Venezuela.

Relatively little conspicuous age variation is apparent within the family. Most individuals in juvenile plumage resemble those in adult non-breeding plumage; in sexually dimorphic species, young in their first-winter plumage tend to resemble adult females. White-crowned Sparrows (*Zonotrichia leucophrys*) are an exception. In their first winter, White-crowned Sparrows have a rusty tone in the crown where the adults are black. They lose this rusty colour by a partial pre-breeding moult that occurs before the spring migration and before they breed for the first time. Otherwise, most American sparrows during their first winter are like adults in appearance, although commonly somewhat duller in colour, with buffy tones.

The very long spike-like bill is perhaps the most striking feature of the ***Short-tailed Finch****. The tail is, in fact, not particularly short; the short-tailed appearance is created by the big body of this large and thickset bird. Plain lead-grey above and paler grey below, with a grey bill, this species can be distinguished from the similarly plumaged Plumbeous Sierra-finch* (Phrygilus unicolor) *by its larger size and its peculiar bill. Originally placed near the quiscaline icterids, the Short-tailed Finch may be moved to the tanager family (Thraupidae) if it proves to be close to the sierra-finches.*

[*Idiopsar brachyurus*, Pongo, La Paz, Bolivia. Photo: Joe Tobias]



Juveniles of the Band-tailed Seedeater (*Catamenia analis*) are similar in plumage to the adult female, but are generally much browner and more densely streaked on both the upperparts and the underparts. This seedeater shows much variation in subadult plumages, and, like the two other species in this Neotropical genus, it has a complex cycle of ageing. Both sexes appear to have two immature post-juvenile stages before acquiring the adult plumage. Males become progressively less streaked and

The five Incaspiza *inca-finches are rather long-tailed, with a slim, pointed orange-yellow bill. Four of the species, including the* ***Rufous-backed Inca-finch****, are found in and around the poorly known dry inter-Andean valley of the Río Marañón, in northern Peru. All five have small ranges; the Grey-winged Inca-finch* (Incaspiza ortizi) *possibly has a global distribution of no more than 1300 km². The Rufous-backed Inca-finch is sometimes considered conspecific with both the Grey-winged and the Great Inca-finches* (I. pulchra), *the latter, despite its name, being the smaller of the two.*

[*Incaspiza personata*, Huaylas, Peru. Photo: Lieven De Temmerman]

Species diversity of the Poospiza *warbling-finches is concentrated in the Andes of Peru, Bolivia and Argentina. Fifteen species are recognized here. Cytochrome* b *sequences of the two races of the* ***Ringed Warbling-finch****, however, differ by as much as 4·4%, equivalent to the difference between undisputed* Poospiza *species. Similarly, two races of the* ***Black-and-rufous Warbling-finch*** *are sometimes treated as forming a separate species.*

[Left: *Poospiza torquata torquata*, Monteblanco, Santa Cruz, Bolivia. Photo: Daniel Alarcón.

Right: *Poospiza nigrorufa nigrorufa*, Ribera Norte, Buenos Aires, Argentina. Photo: James Lowen]

more solidly and darker greyish above and below. Similarly, younger females are more heavily streaked than older ones, and adult females are the most greyish and the least streaked of all. More research is required in order to determine the full extent of variation in this pattern, and, in particular, whether or not it applies throughout all of the species' extensive range, which runs from the far north of Colombia southwards in the Andes as far as north-west Argentina.

A recent study by R. Maia and R. H. Macedo investigated the prenuptial moult pattern of the Blue-black Grassquit and whether or not it predicted the presence of iridescent structural coloration in this species' plumage. During three breeding seasons, the scientists captured males of this species and measured morphological variables and breeding-plumage coverage, and also collected feathers for spectrometry examination. It was found that saturation of the iridescent coloration was positively

The Sicalis *yellow-finches are birds of open country, from arid lowlands to the high Andean* puna. Sicalis *species are found from Mexico southwards throughout South America to southernmost Chile, Patagonia and Tierra del Fuego. Although all have some yellow, some are predominantly olive, green or brownish. They vary greatly in proportions and bill size. The* ***Orange-fronted Yellow-finch*** *is a compact yellow-finch with a very short tail and wings and a large and rounded head. Its bill is large for the bird's size. Molecular data indicate that the yellow-finches are close to the "hooded" group of the* Phrygilus *sierra-finches.*

[*Sicalis columbiana leopoldinae*, Tocantins, Brazil. Photo: William Price]

Until the early 1980s, the genus Emberizoides *was thought to be monotypic, comprising the* ***Wedge-tailed Grass-finch****. The Duida Grass-finch* (Emberizoides duidae) *is restricted to the Cerro Duida, in southern Venezuela, but the ranges of the Wedge-tailed and Lesser Grass-finches* (E. ypiranganus) *overlap in Brazil, Argentina and Paraguay. All three species have a very long tail, with the inner two pairs of rectrices longer and sharply pointed. In playback experiments, the nominate race of the Wedge-tailed Grass-finch does not react to songs from the race* apurensis, *suggesting that yet another species may be involved.*

[*Emberizoides herbicola herbicola*, Chapadão do Céu, Goiás, Brazil. Photo: Dante Buzzetti]

related to relative moulting speed, indicating that males which invested more in pre-breeding moult also produced more saturated, UV-shifted plumage. The body condition of individuals was not related to brightness or saturation of the iridescent plumage, and no male morphological attributes were associated with the coloration or size of the white underwing patch. The findings indicated that the moult pattern, and possibly that of feather growth, might affect the organization of optical nanostructures responsible for iridescent coloration, and also that the ontogeny of iridescent plumage ornamentation must be taken into consideration when developing hypotheses regarding honest advertisement of such signals. The coloration of the male Blue-black Grassquit may be a reliable reflection of the amount of energy allocated to the moulting process, thereby constituting an honest indicator of male quality. It appears that this is the first study in which natural variation in moulting

The ***Coal-crested Finch*** *is a small, plump-bodied finch with a distinctive thin spiny crest springing from its forehead and forecrown. The crest is often held flat. The female is much duller than the male, and her crest is brownish and poorly developed. This species is often considered a fire specialist, and has been observed invading recently burnt areas of the* cerrado. *The monotypic genus* Charitospiza *probably belongs in the tanager family (Thraupidae).*

[*Charitospiza eucosma*, Chapada dos Guimarães, Mato Grosso, Brazil. Photo: Edson Endrigo]

*The spectacular crest of the **Red-crested Finch** is usually held flat. This species and the Pileated Finch* (Coryphospingus pileatus) *are often considered conspecific and are reported as hybridizing in Brazil. But they show 5·9% DNA-sequence divergence, reflecting a long history of isolation. In addition to DNA, the red-and-black plumage, the relatively thin bill and the presence of a crest all support the placement of* Coryphospingus *in a clade of lowland tanagers that includes* Tachyphonus, Ramphocelus, Eucometis *and* Lanio.

[*Coryphospingus cucullatus cucullatus*, Capão do Leão, Rio Grande do Sul, Brazil. Photo: Edson Endrigo]

pattern has been found to be associated with sexually selected structural colour in the plumage.

In a different study, P. Benites and colleagues examined wavelength-reflectance data with regard to the plumage of four female seedeaters, the Tawny-bellied (*Sporophila hypoxantha*), Dark-throated (*Sporophila ruficollis*), Chestnut-bellied (*Sporophila castaneiventris*) and Rufous-rumped Seedeaters (*Sporophila hypochroma*). The females of these closely related species are very difficult to differentiate on appearance alone. Reflectance values were measured on museum skins, and differences among the species were analysed. It was found that interspecific distances in the colour space were considerably higher than the threshold for colour discrimination, indicating that there were differences in colour among species that should be detectable by the birds themselves. The greatest colour differences were between the Tawny-bellied Seedeater and the other three species. Ultra-violet wavelength was particularly important in discriminating between the species. From these findings, it is apparent that the females of these four seedeaters differ considerably in plumage, although the differences are imperceptible to the human eye.

Moults of emberizids generally follow much the same pattern. After fledging, the young undergo a partial post-juvenile moult, known also as the first prebasic moult, which usually involves the wing-coverts, some body plumage and, for some species, the tertials, and is generally completed on the breeding grounds. With a few species, such as the Corn Bunting, this moult is complete. Among adults, the commonest strategy is for a single complete moult once each year, whereby the bird replaces all of its feathers during the same period, normally immediately after the breeding season. Migratory species sometimes need to complete this post-breeding moult quickly, in order to be able to make the flight to their non-breeding grounds without delay. Those breeding in the far north, such as the Snow Bunting, may become almost flightless for a brief period, as they renew the flight-feathers in a very rapid sequence. Some others begin to moult while on the breeding grounds and then suspend the moult during their migration, completing it when they reach their winter quarters. Species having distinct "winter" and "summer" plumages, such as the Lark Bunting and the longspurs and snow buntings, among others, acquire the summer plumage mostly by means of plumage wear. The brightly coloured contour feathers often have buffy tips, which obscure the rest of the feathers and make them appear drab in winter; after a few months during which the feathers are subject to continuous abrasion, the brighter colours are finally exposed. In the spring, generally before migration, there is often a pre-breeding moult, known also as the prealternate moult. For some species, such as the Saltmarsh Sparrow, this is extensive, often involving the rectrices, but for most it is partial. Longspurs, for example, generally renew only a few head feathers in this moult. The pre-breeding moult is generally completed while the bird is still on the wintering grounds, but some species may not complete it until after their arrival on the breeding grounds.

The above details of moult apply mainly in the Northern Hemisphere. Far less is known about the moult process in the tropics, where the seasons are less well marked and where breeding may take place over longer periods and/or during several different periods during a single year. From the limited information available, it is likely that adults undergo a complete moult once yearly.

Males of some of the "capped" seedeaters, or "capuchinos", in the genus *Sporophila* are well known for moulting into a dull non-breeding plumage, at which time they appear much more

All members of the genus Paroaria *are adorned with red somewhere on the face or throat, and have a variably developed crest. They differ in the distribution or lack of black on the face, in bill colour and in the colour of their upperparts, from greyish to blackish. All are whitish below. The **Crimson-fronted Cardinal** may form a superspecies with the Masked* (Paroaria nigrogenis), *Red-capped* (P. gularis) *and Yellow-billed Cardinals* (P. capitata).

[*Paroaria baeri baeri*, Kuryala Lodge, São Felix do Araguaia, Mato Grosso, Brazil. Photo: Edson Endrigo]

With 31 species presently recognized, Sporophila *is the second largest genus in the family after* Emberiza. *Molecular evidence suggests that* Oryzoborus *is closely related and should perhaps be subsumed in* Sporophila, *which would add six species. Along with the grassquits, seedeaters are the smallest emberizids, 7–15·5 g in weight and 8·5–12 cm in length. They have a short, thick bill. They are strongly dichromatic, the males colourful or boldly patterned. The females are quite drab and, to human eyes, very similar to one another, but, when ultraviolet wavelengths visible to birds are included, their plumages are found to be considerably divergent in colour. The* ***White-bellied Seedeater*** *is one of the largest in the genus, with a deep, very short, rounded bill.* ***Dubois's Seedeater*** *is very closely related to the Yellow-bellied Seedeater* (Sporophila nigricollis), *or conspecific with it or even a morph of that species. Molecular-genetic data indicate that the* ***Rusty-collared Seedeater*** *belongs in a clade with the Yellow-bellied Seedeater. Its plumage becomes brighter from north to south. The* ***Chestnut Seedeater*** *is one of the southern clade of the "capuchino group" of seedeaters. The very low sequence divergence among the eight species in this clade suggests that radiation occurred very recently, probably within the last half-million years.*

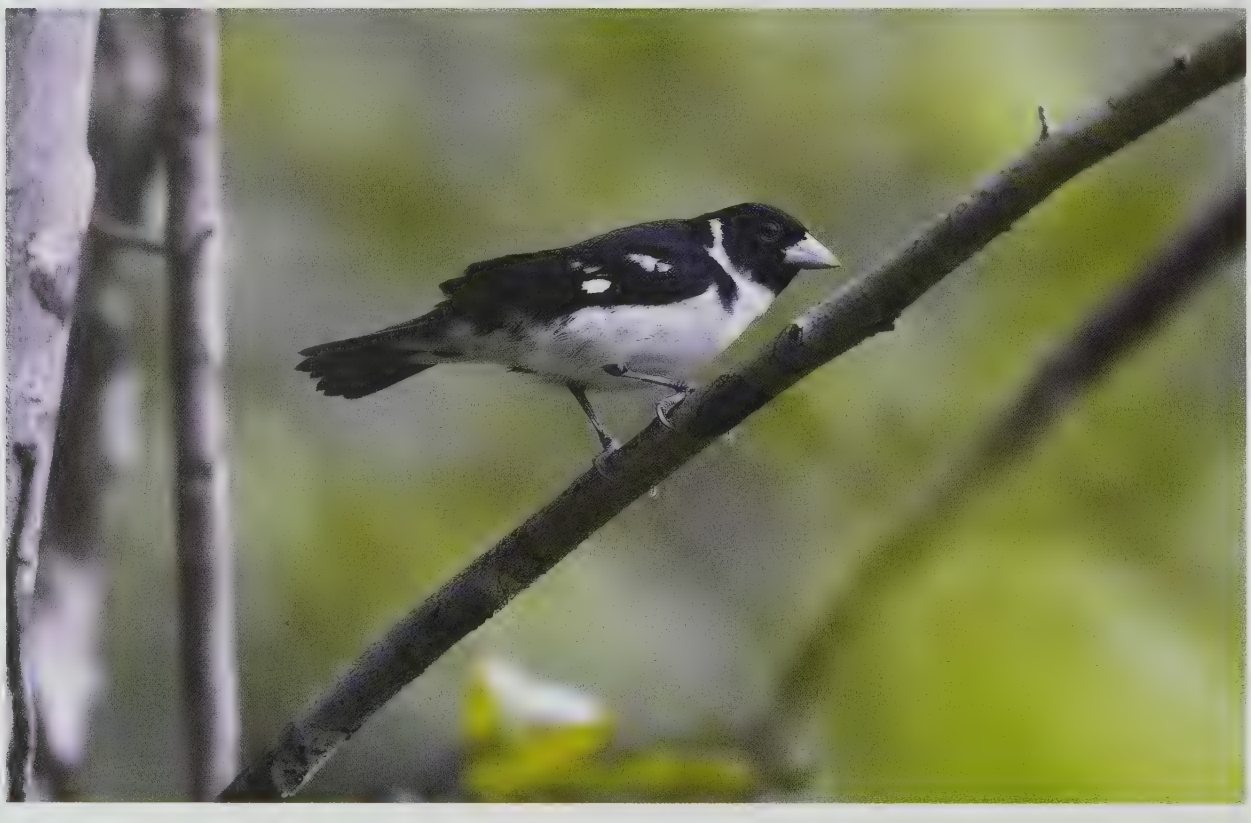
Below right: *Sporophila cinnamomea*, Candiota, Rio Grande do Sul, Brazil. Photos: Edson Endrigo]



*The male **Chestnut-bellied Seed-finch** differs from all the others in the genus in his chestnut-coloured underparts. The males of the other five species are entirely black, except for white patches at the base of the primaries. (One species lacks these; another also has white patches at the base of the secondaries and on the underwing-coverts.) All* Oryzoborus *species have a large, heavy bill, and the bills of the Large-billed* (Oryzoborus crassirostris) *and Great-billed Seed-finches* (O. maximiliani) *are so massive that the crown appears to sweep back from the base of the upper mandible, making the birds look flat-headed.*

similar to their respective females. It is not certain, however, that all southern members of the capped group, which consists of the Capped Seedeater (*Sporophila bouvreuil*) and the Tawny-bellied, Rufous-rumped, Dark-throated, Marsh, Chestnut and Black-bellied Seedeaters (*Sporophila melanogaster*), do adopt such plumage. Nor is it known whether the males of either of the two northern capuchinos, namely the Ruddy-breasted and Chestnut-bellied Seedeaters, moult into a female-like plumage after breeding.

Habitat

Buntings and New World sparrows are found in a variety of habitats, but characteristically they spend much of the time close to the ground. They forage generally on or near the ground, and they commonly place their nests on the ground or low in vegetation, often under tussocks of grass or similar vegetation. Nevertheless, many members of the family commonly sing from trees and bushes. Many species, such as the Rock Bunting (*Emberiza*

*The **White-naped Seedeater** is a rare and patchily distributed endemic of white-sand scrub in the Guianan Shield region of Colombia, Venezuela, Brazil and Guyana. Molecular work indicates that* Dolospingus *is very close to* Sporophila *and should perhaps be merged with it. The White-naped Seedeater shares its black-and-white plumage with at least five* Sporophila *species, and may fill a void in a* Sporophila *allospecies complex which is otherwise absent from the Guianan Shield.*

[*Dolospingus fringilloides*,
Mitú, Vaupés, Colombia.

A small finch-like bird with a relatively slim and slightly decurved bill, the ***Orangequit*** *is confined to the island of Jamaica. Unusually for the Emberizidae, it is a nectar specialist. The evolutionary relationships of the monotypic genus* Euneornis *are unknown. It has been suggested that this and other problematic Caribbean island taxa are remnants of an ancient and widespread lineage that has since become extinct in mainland South America. Alternatively, they may represent a very recent lineage which has had more success in colonizing islands than in competing with mainland species. The Orangequit is sometimes placed in the tanager family (Thraupidae), with which it perhaps has closer ancestral affinities.*

[*Euneornis campestris*, Marshall's Pen, Jamaica. Photo: Neil Bowman/FLPA]

cia), often select a nesting site in a cleft in rocks, or sometimes under a roof. The six longspurs and snow buntings breed primarily in treeless terrain and always nest on the ground, commonly among rocks. Marsh-dwelling species, such as the Seaside, Nelson's, Saltmarsh and Le Conte's Sparrows and the Swamp Sparrow, place their nests low down, above water level, and in tidal areas generally above the mark of the highest tides. The Reed Bunting (*Emberiza schoeniclus*) breeds in dense, moist vegetation, which means that this species is generally associated with marshes, fens and bogs, but its nest-site preference is apparently related more to vegetation than to a need for an aquatic site. In some parts of its range, such as in southern England, this bunting also visits gardens, especially during the winter months, in order to forage. Some species, such as the Chipping Sparrow (*Spizella passerina*), commonly nest in trees, occasionally more than 10 m up, but even these often forage on the ground.

In addition to the longspurs and snow buntings, which may belong in their own family, Calcariidae (see Systematics), typi-

Along with the seedeaters, the grassquits are the smallest emberizids. The ***Cuban Grassquit*** *is 11·5 cm in length and weighs just 6–9·5 g. Most grassquits are sexually dichromatic; the duller female Cuban Grassquit has a dark chestnut (instead of black) face and a paler yellow collar. The male Dull-colored Grassquit* (Tiaris obscurus)*, however, differs from the males of the other four species in its plain, brownish plumage, which resembles that of the female and juvenile. It has been suggested that this plumage may have originated through the evolutionary retention of immature plumage from a dichromatic ancestor species (paedomorphosis).*

[*Tiaris canorus*, Las Terrazas, Cuba. Photo: Zhao Chao]

The four Caribbean species in the genus Loxigilla *get their English name of "bullfinch" from the short and rounded bill. The Greater Antillean* (Loxigilla violacea) *and Lesser Antillean Bullfinches* (L. noctis) *have, respectively, five and eight island or island-group races. The Barbados Bullfinch* (L. barbadensis) *was formerly considered a race of the Lesser Antillean Bullfinch. The* ***Puerto Rican Bullfinch*** *has one extant race, confined to Puerto Rico; the much larger race* grandis, *found on St Kitts, and sometimes considered a full species, has not been reported since the 1920s and is thought to be extinct.*

[*Loxigilla portoricensis portoricensis*, Puerto Rico. Photo: Adrian & Jane Binns/ VIREO]

cal emberizids breed at high latitudes and from low to high elevations. They can be found from sea-level to above 5000 m. In South America, the Bright-rumped Yellow-Finch (*Sicalis uropigyalis*) is found at up to 4800 m in grasslands in the Andes, and the White-winged Diuca-finch (*Diuca speculifera*) ascends even higher, to 5500 m, with nesting recorded at 5400 m; several of the *Phrygilus* sierra-finches live above 4500 m. In Central America, Volcano Juncos (*Junco vulcani*) are commonest above the tree-line, to at least 3000 m. Some of the buntings of Eurasia can also be found at high elevations. For example, the Rock Bunting occurs at up to 4000 m in Asia, and the Tibetan Bunting (*Emberiza koslowi*) lives on relatively barren, steep scrubby slopes above the tree-line between 3600 m and 4600 m. The last-mentioned species favours a mixture of dwarf alpine shrubs, especially cotoneaster (*Cotoneaster*), juniper (*Juniperus*), barberry (*Berberis*) and others, at the base of steep cliffs in areas where the alpine grassland is grazed seasonally by yaks (*Bos grunniens*).

Harris's Sparrow (*Zonotrichia querula*) breeds in the forest–tundra ecotone in Canada, where it is locally very common, although many aspects of its life are still little known. On the other side of the Atlantic Ocean, the taiga of northern Eurasia is the breeding habitat of several buntings, including the Rustic Bunting (*Emberiza rustica*) and the Chestnut Bunting (*Emberiza rutila*).

Recent molecular-genetic research suggests that the Galapagos group consisting of the genera Certhidea *(the* ***Green Warbler-finch****, left),* Camarhynchus *(the* ***Small Tree-finch****, centre),* Geospiza *(the* ***Large Ground-finch****, right) and* Platyspiza, *collectively known as "Darwin's finches", is allied to the tanagers (Thraupidae).*

[Left: *Certhidea olivacea*, Genovesa, Galapagos. Photo: Tui de Roy/ Roving Tortoise Photos.

The Snow Bunting is circumpolar in distribution. In the Old World it breeds north into the high Arctic, including Iceland, Spitsbergen and Novaya Zemlya, and in the New World it nests in the Aleutian and Pribilof Islands, Alaska, northern Canada, including the arctic islands, and Greenland. Snow Buntings commonly nest in dry, sparse rocky areas. The similarly circumpolar Lapland Longspur also breeds in the high Arctic. At the other end of the globe, in South America, many finches and seedeaters breed at high altitudes in the Andes, among them the Paramo Seedeater (*Catamenia homochroa*) and its two congeners, the Short-tailed Finch, and most of the sierra-finches. These occur in *páramo* and *puna* grasslands and in timber-line bushes, often foraging on the ground. The Peg-billed Finch (*Acanthidops bairdi*) of Central America is also found above the timber-line. Brewer's Sparrow (*Spizella breweri*) of North America uses two distinctly different breeding habitats: the nominate race breeds in sagebrush (*Artemisia*) grasslands and in pine–oak savanna over a wide range of elevations; race *taverneri* breeds in dwarf balsam fir–willow (*Abies balsamea–Salix*) or birches (*Betula*) at or above the timber-line. The elevational ranges of these two populations do not overlap. In high mountains in western North America, as well as in the north, White-crowned Sparrows breed in krummholz, at or above the tree-line, where they place their nests in dwarf spruce (*Picea*), balsam or birches. In the west, however, they commonly occupy deciduous thickets along the coast, or make use of urban gardens for nesting purposes.

Farther south, in Middle America and the Neotropics, the Blue-black Grassquit is often abundant in seasonally wet grassland or open bushy habitats at lower elevations up to 1100 m, in some places ascending to 2600 m, and the *Sporophila* seedeaters in general are found in lowland grassland, often in tall grasses near water. Although most *Sporophila* species live in grassland or in grassy areas with scattered deciduous shrubs, the Slate-colored Seedeater occurs mostly in woodlands, and may place its nest as high as 5 m above the ground. Brush-finches in the genera *Atlapetes* and *Arremon* are denizens of the understorey of humid forests or forest edge. The Sooty-faced Finch (*Arremon crassirostris*) favours wet woodlands bordering swift rivers and streams, and the *Oryzoborus* seed-finches are likely to be encountered in shrubby clearings. The Blue Seedeater (*Amaurospiza concolor*) is generally an uncommon species, and in Costa Rica and Panama is characteristically found in bamboo thickets at overgrown forest borders and secondary woodland. In Mexico this species occurs also in humid pine–oak woodland and even in cloudforest, and in the Neotropical part of its range, from south-west Colombia south to northern Peru, it is often found away from bamboo.

Several New World sparrows inhabit dry grasslands, often living in grassland with sparse, small trees and shrubs. In the arid grasslands of the south-western USA, Cassin's Sparrows and Lark Buntings can be common as breeding birds. Their breeding ranges fluctuate with variation in the climate, and during dry periods may extend farther east than they do in wetter years. In some areas, McCown's and Chestnut-collared Longspurs breed in the same fields, but the former are generally found in drier sites with sparse vegetation, whereas the Chestnut-collared are likely to settle in more mesic areas with taller grasses; the range of the Chestnut-collared Longspur extends farther east than that of McCown's. Rufous-winged Sparrows prefer flat desert grassland interspersed with xeric shrubs, and are commonly seen along ephemeral washes. Rufous-crowned Sparrows, on the other hand, are found in dry rocky hillsides and canyons, and Black-throated Sparrows can be encountered in similar sites, but generally favour more open, rocky sites with scattered desert shrubs. In the western USA, in the Great Basin and eastern California, Sage Sparrows breed in cold desert with saltbush (*Atriplex*) or in semi-desert with sagebrush, where they typically occur in dry grasslands interspersed with sagebrush, saltbush, and scattered junipers or pines; outside the breeding season they can be found in antelopebrush (*Purshia*) and rabbitbrush (*Chrysothamnus*). Bell's Sparrow, which is commonly treated as conspecific with the Sage Sparrow, breeds in "hard" chaparral dominated by dense chamise (*Adenostoma fasciculatum*), and less often in coastal California sagebrush (*Artemisia californica*) or brittlebush (*Encelia farinosa*) and in mixed brush on sand dunes near the coast. The range of Bell's Sparrow extends southwards through Baja California, in north-west Mexico, and here the species is found also in scrub dominated by wolfberry (*Lycium*), known locally as "frutilla".

*The **Yellow-billed Cardinal** is usually seen in pairs, family parties or small groups. Outside the breeding season, larger flocks may form. Straggling flocks of hundreds, with a large proportion of immatures, have been reported. They regularly congregate around settlements to feed on grain and food scraps. Juveniles of the congeneric Red-capped Cardinal* (Paroaria gularis), *which is highly territorial when breeding, flock with the adults until the dull orange plumage of the head starts to change to the bright red of the adult, at about one year of age, when they become targets of aggression from the adult male.*

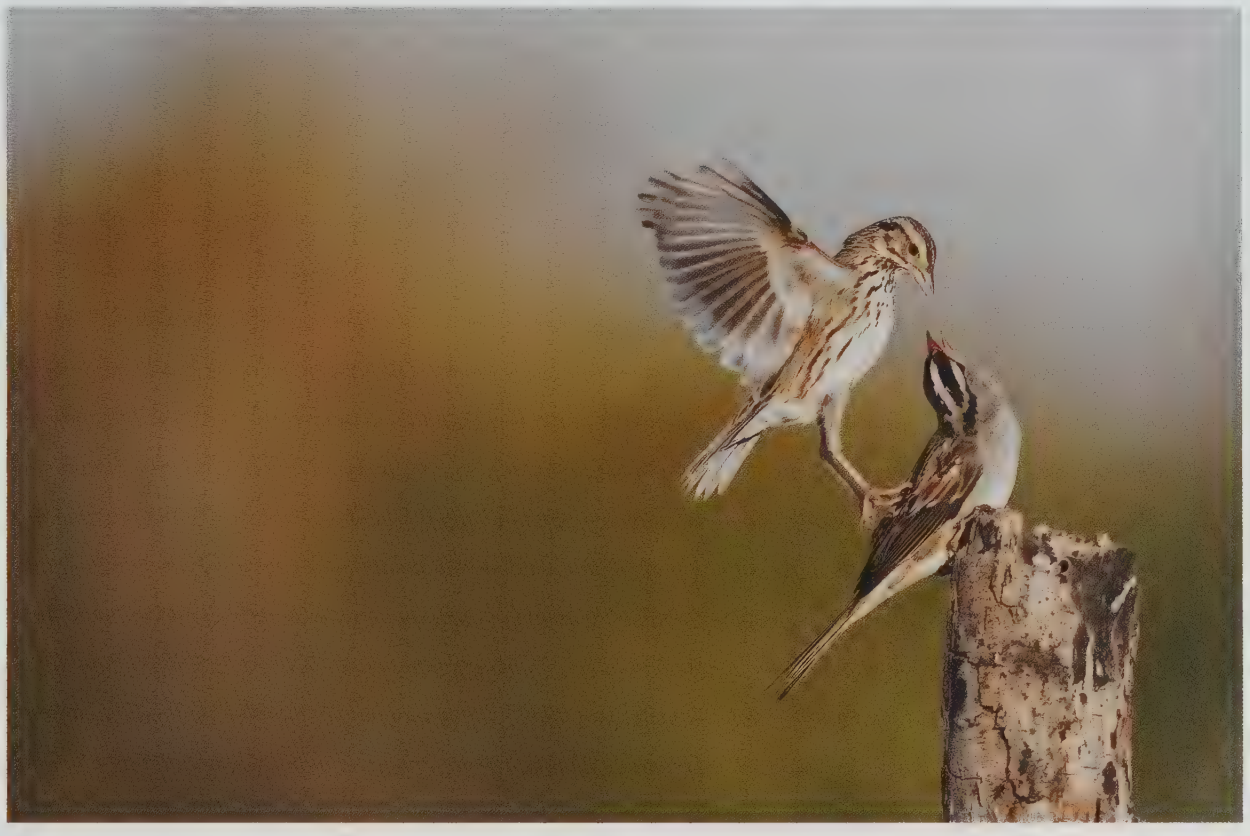
[*Paroaria capitata capitata*, Pantanal, Mato Grosso, Brazil. Photo: Fabio Colombini]

On the Pacific Coast of North America, Belding's (*Passerculus guttatus*) and Large-billed Sparrows (*Passerculus rostratus*), both often treated as being conspecific with the Savannah Sparrow, breed in coastal saltmarshes dominated by pickleweed (*Salicornia*), iodinebush (*Allenrolfea occidentalis*), sea blight (*Suaeda*), saltbush and saltgrass (*Distichlis spicata*). On the Atlantic coast, Seaside Sparrows and also Nelson's and Saltmarsh Sparrows breed in dense smooth cordgrass (*Spartina alterniflora*), blackgrass (*Juncus gerardii*), cat-tail (*Typha*) and marsh-elder (*Iva*) habitats that are sometimes flooded at high tides.

Most of the species breeding at high latitudes or at higher-lying elevations undertake seasonal movements, shifting to more hospitable climes during the non-breeding period (see Movements). Many then choose habitats similar to those in which they breed, although there are some differences. The Yellowhammer of the Western Palearctic is partially migratory, all of the northernmost breeding birds moving to areas farther south, but generally still within the species' total breeding range. In the winter months, as in the breeding season, they avoid dense woodlands and wetlands, and heavily populated areas, but they can be found in hedgerows, at forest edges and in parkland and similar semi-open habitats. The Ortolan Bunting (*Emberiza hortulana*), in contrast, is a long-distance migrant. On its breeding grounds from north, central and south-west Europe eastwards to central Mongolia and, in the south, to Turkmenistan, it prefers cool, open woodlands, often open pine woodland or forest-steppe in low mountains, ascending to about 2500 m; in its wintering areas in sub-Saharan Africa, this bunting is found in subtropical upland savannas, grasslands and cleared forests, and in semi-arid cultivation, especially in open upland habitats, generally between 1000 m and 3000 m.

Although none of the North American sparrows is a long-distance migrant, most do migrate short distances. Species that

*Outside the breeding season, **Snow Buntings** are generally found in flocks, which can include tens to hundreds of individuals. In the winter of 2004–2005, concentrations of up to 1600 Snow Buntings were recorded in Lower Silesia, in south-west Poland. Average flock size on snowless days was eleven times higher than on snowy days. Snow Buntings form both single-species flocks and mixed flocks with Horned Larks* (Eremophila alpestris) *and Lapland Longspurs* (Calcarius lapponicus). *They can also be found singly and in twos and threes. Flocks of males may arrive in the breeding area 2–3 weeks ahead of females.*



[*Plectrophenax nivalis nivalis*,
New York, USA.

breed at high latitudes move southwards in autumn, but most do not venture south of the USA or central Mexico. In winter, the sparrows tend to form loose flocks, often of mixed-species composition, as also do most of the buntings in the Old World. Weedy fields and hedgerows, and open woodlands with a shrubby understorey are among the favoured habitats. Outside the breeding season, longspurs and Snow Buntings are generally found in flocks, and at times in rather large flocks, those of Snow Buntings commonly consisting only of individuals of that species, but sometimes mixed with Horned Larks (*Eremophila alpestris*) and Lapland Longspurs. They then occur in pastures and large fields, along roadsides, and along the shoreline. Snow Buntings generally stay on the ground, but they will at times alight in a tree in open country. Likewise, wintering flocks of longspurs often contain only a single species, but mixed flocks, especially with Horned Larks and other longspurs, can also be observed, not surprisingly, especially where the wintering ranges of several populations overlap. They almost invariably remian on the ground, but occasionally they will perch on a fence, on a telephone wire or in a small tree.

*The "bill-tilting" or "head up" threat display, shown here by the **Many-colored Chaco Finch**, has been recorded for many emberizids and is common also among the icterids. It is usually performed by members of the same sex in agonistic situations, such as territorial boundary disputes between males. The feathers of the head and neck are sleeked, and the birds are usually silent. Many-colored Chaco-finches sing persistently even through the hottest part of the day.*

[*Saltatricula multicolor*,
Perforación,
Santa Cruz, Bolivia.
Photo: Joe Tobias]

*The male **Savannah Sparrow** defends his territory by singing from border perches, chasing intruders, walking side by side along the boundaries with males of adjoining territories, or assuming threatening postures face to face at the borders. Sometimes, disputes also involve chasing birds of other species, as illustrated by this one attacking a White-crowned Sparrow* (Zonotrichia leucophrys). *In a field study in south-east Michigan, the males seldom left their territories except under stress, but adults accompanying fledglings could cross boundaries with impunity.*

[*Passerculus sandwichensis sandwichensis*, Sinton, Corpus Christi, Texas, USA. Photo: Imagebroker/photolibrary.com]

Several species of emberizid are confined to the Caribbean islands. In Cuba, the Cuban Bullfinch (*Melopyrrha nigra*) breeds in forests and mangroves, as well as in bushy areas and undergrowth in open pinewood areas, while the Cuban Grassquit (*Tiaris canorus*) is found primarily in semi-arid country, often near the coast, and also in open pine stands, brushy areas, shade coffee and citrus plantations, and rural farmland with shrubbery. The Zapata Sparrow (*Torreornis inexpectata*) occurs as three distinctly different ecological forms: the nominate race lives in seasonally flooded sawgrass prairies with scattered shrubs in the Zapata Swamp, in west Cuba, the subspecies *varonai* inhabits dry to semi-wet open forest in Cayo Coco, in north Cuba, and the subspecies *sigmani* inhabits coastal thorn-scrub, dry forest and cactus stands in Guantánamo, in the south-east of the island. Jamaica is the home of the Yellow-shouldered Grassquit and the Orangequit. The former can be found at the edges of forest, including montane evergreen forest, and in woodland, as well as in gardens where these are close to wooded areas. The Orangequit is more a species of humid forest, but is commonly encountered also in shade coffee plantations. The Puerto Rican Bullfinch (*Loxigilla portoricensis*),

*The crest of the **Red-crested Cardinal**, usually held flattened and pointing backwards, is raised when the bird is excited, giving it a shaggy appearance. In captivity, breeding-age males are said to become noticeably aggressive, "charging at the cage walls, calling, stretching their necks and engaging in combat anything that moves". They are non-territorial outside the breeding season. In Manu National Park, in Peru, Red-capped Cardinals* (Paroaria gularis) *defend territories along the shores of oxbow lakes and rivers, each territory containing two short stretches of shore on opposite sides of the water.*

[*Paroaria coronata*, Pantanal, Mato Grosso, Brazil. Photo: Cassiano Zaparoli]

The preening and other feather maintenance and comfort behaviour of emberizids appear to be typical of passerines. This preening ***Nightingale Finch*** *is an adult male.* Nesospiza *plumages vary with age and sex; immature plumage is retained for at least two years. In experiments with another emberizid, Dark-eyed Juncos* (Junco hyemalis) *were able to discriminate between the preen-oil odour of their own and other species. Unexpectedly, females spent more time with the odour of smaller males, even though their odours were less "male-like" than those of larger males.*

[*Nesospiza questi*, Nightingale Island, Tristan da Cunha Group. Photo: Peter Ryan]

restricted to the island of that name, breeds in dense mountain forest and tropical lowland forest, as well as dry coastal thickets and, on occasion, mangroves. The more widespread Greater Antillean Bullfinch (*Loxigilla violacea*) inhabits dense thickets and undergrowth in various habitats, including pine savanna and gardens, wet upland forest and dry coastal scrub; its range incorporates the Bahamas, Jamaica and Hispaniola, including some of the latter's offshore islands. The Lesser Antillean Bullfinch (*Loxigilla noctis*), which ranges from the Virgin Islands southwards through most of the Lesser Antilles to Grenada, lives in tropical evergreen forest and deciduous woodlands, venturing also into second growth and gardens, and sometimes dry areas and mangrove swamps. Far more restricted in range, the St Lucia Black Finch, found only on St Lucia, in the south-central part of the Lesser Antilles chain, lives in tropical lowland evergreen forest and secondary forest from sea-level to 950 m; it prefers forest with a relatively complex understorey, usually in moister sites, and is generally more likely to be found in mountains than in the dry lowlands.

All New World sparrows and Old World buntings for which information is available scratch the head by the indirect method, as this ***Buff-bridled Inca-finch*** *is doing. They droop one wing and lift the foot over it, tilting the head to one side. Inca-finches are reported as being relatively easy to observe in the early morning, when they perch openly on shrubs, cacti and boulders, but behaving much more inconspicuously during the rest of the day. The Buff-bridled Inca-finch, which is less shy than others in its genus, often raises its tail abruptly, then slowly lowers it again.*

[*Incaspiza laeta*, Celendín–Balsas road, Marañon Valley, Peru. Photo: Heinz Plenge]

General Habits

Characteristically, buntings and New World sparrows spend much of their time on or close to the ground, foraging on the ground in open country, under low vegetation in brush or in woodland understorey. Many species can be difficult to observe. When approached by a human observer, some prefer to run away and take cover, rather than to take flight. In general, however, they are most easily seen in the early morning. Emberizids often give sharp, staccato contact notes, which can frequently be used for specific identification, although the calls of many of the species are rather similar to one another. If they are silent, the sparrows and buntings are easily overlooked. A well-tried method of luring them out from cover is that of "pishing", making a sound like "pssssh" a few times in quick succession, such as "psh psh psh", which is often effective in attracting a skulking bird out into the open, where it can be observed, even if only for a brief time.

Notwithstanding the often skulking nature of these birds, there are times when they are easily visible and even conspicuous. During the breeding season, males of many species sing from prominent and conspicuous perches, and, in open country, some perform elaborate display-flights, making them easy to observe.

When on the ground, the members of this family move by hopping or running, and most species will do either, depending on the context. Species living in places with sparse ground vegetation, such as the longspurs, the two snow buntings and some populations of Sage Sparrows, commonly run; when moving over only short distances, hopping is the more usual method of locomotion for most species. Some will walk slowly while foraging, and then run or hop when moving more rapidly.

The long-distance flight of sparrows is usually direct, or slightly undulating. This contrasts with the short flights of many species, especially those that are characteristically found in brushy and old-field habitats, such as the *Aimophila* sparrows and the Song Sparrow, which is seemingly laboured and "floppy", with brief bursts of flapping. Short flights of species that live in open fields, for instance the Savannah Sparrow (*Passerculus sandwichensis*), the longspurs and the Snow Bunting, are direct. The migratory species may form loose flocks during passage movements. Diurnal migrants, such as the longspurs and the Snow Bunting, often move in large flocks. When flying in flocks, sparrows and buntings commonly utter calls, and these call notes are, perhaps always, species-specific (see Voice). Juncos and other sparrows with white in the tail, such as the Vesper Sparrow and the longspurs, flick the tail, showing the white, when on the ground.

Many species of New World sparrow have flight displays, and these can sometimes be elaborate. As an example, male Cassin's Sparrows leap into the air to a height of about 6 m, and float downwards on set wings, while singing. Similarly, Lark Buntings and McCown's Longspurs have elaborate aerial songs: they

When bathing, the ***White-crowned Sparrow*** *wades into still or slowly moving shallow water, and dips and splashes about, thrusting its head beneath the water, and fluffing its feathers to ensure that its plumage is thoroughly wet. After bathing, the sparrow may squat in a flattened posture in a sunny spot, occasionally preening, and turning its head from side to side to look around as its feathers dry. The posture is different from that used in sun-bathing, and the feathers are not fluffed so as to expose their bases. White-crowned Sparrows have also been seen to use wet leaves to bathe.*

[*Zonotrichia leucophrys*, Roma, Texas, USA. Photo: Arthur Morris/ Birds As Art]

The typical song of an Emberiza *bunting is a short series of simple notes, with little variation. The* ***Ortolan Bunting*** *sings from a prominent perch, and more rarely in a short song flight. Its song consists of 5–6 notes in two parts, the first with a ringing quality, the second lower-pitched and melancholy. The song varies individually and geographically, but recalls an abbreviated version of the Yellowhammer's* (Emberiza citrinella) *song, which is a series of 5–12 notes ending in a drawn-out descending note on a different pitch. Corn Buntings* (E. calandra), *in regions where they have become rare, may sing perfect renditions of Yellowhammer and Ortolan Bunting songs.*

[*Emberiza hortulana*, Gredos, Ávila, Spain. Photo: Jesús Rodríguez-Osorio]

*The song of the **Black-throated Sparrow** appears to be divided into two general sections: an introduction, containing a croak and a complex of notes, and a repetitive section made up of trills or buzzes, or both. The birds achieve variability in their individual repertoires by combining the basic elements in different arrangements. Unlike many other North American sparrows, male Black-throated Sparrows do not necessarily sing from prominent perches, but often deliver their songs from the middle of a shrub or from the ground.*

[*Amphispiza bilineata deserticola*, Anza-Borrego Desert State Park, California, USA. Photo: Tim Zurowski/ photolibrary.com]

rise to 10–20 m or so, with slow stiff wingbeats, singing vigorously, and then glide back to the ground. In a display similar to this, the male Lark Bunting flashes the large white patches on its wings, and both species flash the white in the tail.

Maintenance activities and comfort behaviour by emberizids appear to be fairly normal. Chipping Sparrows, the group of *Ammodramus* sharp-tailed sparrows, the *Passerella* fox-sparrows, juncos, the Song Sparrow and the Lapland Longspur are all known to scratch the head by the indirect method, bringing a foot over one wing, which is slightly drooped, as they tilt the head to one side. Old World buntings have been observed to use the same method for head-scratching, and apparently most sparrows scratch in this manner. Sunning and, especially, water-bathing have been recorded for some of the better-known members of the family, and both seem to be much as would be expected for small to medium-sized passerines. When bathing, for instance, the bird wades into still or slowly moving shallow water, such as a puddle or the shallow margin of a lake or river; there it dips and splashes about, occasionally thrusting the head beneath the water's surface, and fluffs its feathers in order to wet its plumage thoroughly, before coming out and preening. Vesper Sparrows, and other species of open arid grasslands, dust-bathe. They stretch either unilaterally, by extending the wing and leg on one side, or bilaterally, by raising both wings over the back. There are, of course, many species in this family for which no information on comfort behaviour is available, and this is true particularly of the Neotropical species.

Emberizids also drink while standing in water, or they will drink droplets of water from the vegetation. In saltmarshes, Song Sparrows will drink seawater, as do other saltmarsh-dwelling sparrows, although many definitely seem to select fresh water if this is available. For example, while Saltmarsh Sparrows will drink seawater, it was found in tests that they prefer non-saline water, and the same is true of San Benito Sparrows (*Passerculus sanctorum*).

The dawn songs of Atlapetes *brush-finches have highly species-specific patterns, but their songs may be more variable and less distinctive later in the day. The song of the **White-naped Brush-finch** is a deliberate series of notes, sometimes alternating with longer variations, which is transliterated as "oh see, I'm weary, pity me". The Pale-headed Brush-finch* (Atlapetes pallidiceps) *sings from the edges of clearings, or from near the tops of taller bushes or trees. Apparently, only males sing, but partners will give a cascading series of notes in duet when they meet after having been out of each other's sight, or when they encounter another pair.*

[*Atlapetes albinucha gutturalis*, Río Blanco Reserve, Caldas, Colombia. Photo: Ketil Knudsen]

Voice

Many emberizid sparrows give the impression to many people of being rather drab brownish or olive or greenish birds. As unimpressive as their plumage may be to most human eyes, however, they often have songs that are both impressive and musical. The song generally appears to serve both as a way of advertising a territory and as a means of attracting mates. Two males may countersing across territorial boundaries. In addition, they sometimes sing in mid-winter, when they are not on their breeding territories or attempting to mate. Non-conspecific mimicry is uncommon. In Eurasia, the Corn Bunting, which

normally has a simple jangling song, has been reported as singing the songs of some other *Emberiza* species, such as the Ortolan Bunting and the Yellowhammer. This perhaps is best not considered mimicry, but it does reflect the importance of learning in the formation of oscine song. The songs of the *Emberiza* buntings, incidentally, are not very striking, and tend to consist of a short series of simple notes, often with a buzzing quality, and with little variation.

Typically, only the males sing, although the females of many of the species do occasionally sing. The female's song is often not so loud or forceful as the male's, although, because the sexes of most species are similar in appearance, it can be difficult to know if a singing individual is a male or a female. Territorial birds do respond vigorously to playback of their song. Although most members of the family tend to be inconspicuous, when not on territory, they frequently deliver the song from an exposed perch, making them easier for the ornithologist to study. Territorial Bachman's Sparrows, although difficult to see when not on territory, commonly sing from an exposed branch in a pine tree, often from a perch several metres above the ground. This species' song is loud, melodious and varied, and the male will often sing through his many songs for several minutes without moving; when doing this, he certainly is not inconspicuous. The closely related Botteri's Sparrow, although similar in appearance to Bachman's Sparrow, both having rather drab plumage, sings from an exposed perch in a bush or small tree in xeric grassland, and the congeneric Cassin's Sparrow, a bird of open grasslands with scattered bushes, commonly, or perhaps even usually, delivers a flight song; jumping into the air, it sings its song while floating back earthwards on set wings. These species sometimes will sing from a fence. As similar as these three species are in appearance, their songs are quite different, as are their habitat preferences. All three give loud songs that carry well in their open environments, and all three are conspicuous when singing, but otherwise are difficult to see.

Like Cassin's Sparrow, most sparrows and longspurs that breed in open country have flight songs. The aerial song of the Lark Bunting is perhaps typical. The male flies up into the air, and then drifts back to earth with slow stiff-winged beats, singing while doing this. The flight songs and displays of McCown's Longspur and the two snow buntings are similar. The Corn

*The male **Spotted Towhee** usually sings from an exposed perch, often (as shown here) from the top of a bush. The song is variable, typically consisting of two "chip" notes followed by a trill, although on the US Pacific coast it may be a dry buzz, lacking the introductory notes. There are records of female towhees singing. Spotted Towhees hybridize with Eastern Towhees* (Pipilo erythrophthalmus) *in the Great Plains of the USA, although the song of the Eastern Towhee is a quite different and distinctive ringing "drink your tea". In playback experiments, Spotted Towhees did not respond to Collared Towhee* (P. ocai) *songs, although the two commonly hybridize in Mexico.*

[*Pipilo maculatus megalonyx*, San Diego County, California, USA. Photo: Brian E. Small]

Bunting usually sings from a low perch, but it may sing also while flying, often accompanied by a dangling-leg display, and it regularly sings when alighting on a perch. Unlike most New World sparrows, Nelson's Sparrow does not form pair-bonds. Rather, both sexes are promiscuous. The males do not defend territories, but they gather in suitable habitat and display, a performance in which the male flies high into the air, perhaps to more than 50 m, and then floats diagonally downwards while singing its song,

*The **Pale-throated Pampa-finch** and the Great Pampa-finch* (Embernagra platensis) *are birds of grassland habitats with scattered shrubs. Both have loud and distinctive whistled songs which carry well in their open environment. The song of the race* olivascens *of the Great Pampa-finch is more complex, longer and lower in frequency than those of the other races, and on this and other grounds it may merit species rank. Many other grassland emberizids have buzzy, insect-like songs, which can be heard over surprisingly long distances, although the source of the song may be hard to locate.*

[*Embernagra longicauda*, Serra da Gandarela, Rio Acima, Minas Gerais, Brazil. Photo: Edson Endrigo]

Many open-country New World sparrows perform flight displays. The male ***Lark Bunting****, which also sings from the ground and from perches, has an elaborate song flight. He rises several metres into the air and then glides down with slow, stiff flaps of his extended wings. As he does so, he flashes his large white wing patches. Most song flights are given during the first four hours after sunrise, with a lull in the afternoon until just before sunset, when song begins again. When the males first arrive back on the breeding grounds, these displays may be performed communally. The song flights continue at least throughout the incubation period.*

[*Calamospiza melanocorys*, USA.
Photo: Mike Danzenbaker/ AGAMI]

which is reminiscent of the sound made by water being dropped on a hot stove, two or three times, before settling back into the sedge marsh perhaps 100 m from where it first rose to start the display. In the Neotropics, the little Blue-black Grassquit sits on a perch, such as a fence post, and "flits" into the air, flashing the white under its wings, and then drops back to the perch. During these "song-jumps" it gives its buzzy "b-zeer song", or alternatively a simpler "t-s-e-u" song. Song-jumps may be made every few seconds for half an hour or more. The grassquit will also sing while perched.

Aerial displays are obviously useful in communicating information over longer distances, and they are probably particularly useful in environments where there are no convenient singing perches. It is interesting to note that longspurs generally advertise with aerial displays, but when telephone wires are available they will sing from these.

Like other New World sparrows, ***Harris's Sparrow*** *forages on the ground, scratching vigorously in leaves and soil. In the breeding season it also gleans and chases arthropods, and makes aerial sallies to catch insects. Typical breeding habitat includes stands of spruce* (Picea), *and spruce needles and buds are seasonally important in this sparrow's diet. Early in the breeding season, Harris's Sparrows restore their body mass and fat reserves by feeding extensively on tundra fruits such as cranberry* (Vaccinium) *and crowberry* (Empetrum). *Out of season they are often found in mixed flocks with other sparrows, which they tend to dominate by usurping productive food patches.*

[*Zonotrichia querula*, Manitoba, Canada.
Photo: Christian Artuso]

The songs of many grassland sparrows have a buzzy, insect-like quality. It is apparently difficult to pinpoint the source of such songs, and this kind of vocalization also carries well in an open, windy environment. For example, the song of the Grasshopper Sparrow is described as being insect-like, with several buzzy trills on different pitches. That of Le Conte's Sparrow is an insect-like "tzeek-tzzz-tick". The song of Baird's Sparrow has been transcribed as "zhe zhe zheze zurrrrrrr"; the trill at the end of the song is on a lower pitch, and carries well in this species' open environment. Henslow's Sparrow gives a short, but distinctive "tsi-lick", again similar to the sound made by an insect. The song of the Corn Bunting, often given while the bird is in flight, is commonly described as sounding like the sound made by jiggling keys or by splintering glass.

Thicket-dwelling sparrows characteristically have songs that are loud, are often melodious, and can carry for long distances. The Eastern Towhee's song, for instance, is a loud, ringing "drink-your-tea" or "drink-tea". That of the Red Fox-sparrow (*Passerella iliaca*) consists of more than six loud, clear, slurred ringing notes on different pitches, often ending in a phrase that sounds like "aujourd'hui". The song of the Song Sparrow is likewise loud; typically, it starts with two to four loud, clear whistles on the same pitch, followed by a trill, often a buzzy trill, and then several short notes. The songs of Chipping Sparrows and juncos, species that often occur in fairly open woodlands, are similar, and consist of a dry trill, that of the juncos more fluid than that of the Chipping Sparrow.

Several species are known to have geographical song dialects, the Yellowhammer and the Ortolan Bunting being two well-known examples. The song of the Yellowhammer consists of two parts, termed the "initial phrase" and the "final phrase". The male has up to four variations of the initial phrase, these representing song types, whereas the final phrase can differ dialectically. Similarly, the Ortolan Bunting's song has two sections, the second lower-pitched and more melancholy than the first. In this case, it is again the end phrase that is subject to dialectal differences, but often the early phrases of the song also differ regionally.

In the Galapagos Islands, the songs of Darwin's finches consist mostly of various trills and buzzes. The song of the Vegetarian Finch (*Platyspiza crassirostris*), however, is particularly distinctive. It consists of a long, drawn-out nasal note, translit-erated as "ph'wheeeuuuuu-íiíúúú", with the stress towards the end. This note lasts for almost two seconds, and is repeated at intervals. While many of Darwin's finches have a high-pitched call, that of the Vegetarian Finch is most extreme, resembling the electronic sound made when one is tuning in a radio station, "tzeeeeiiiiiiiiippppppp". Its calls also include a rather whining "pheep".

All emberizids have call notes. These can be contact notes or warning notes. They are species-specific, although non-conspecifics often react to warning notes. Although species-specific, some of these calls are far more easily identified than are others. For example, the call note of the Song Sparrow is a distinctive, somewhat hoarse "chimp" or "tchenk", and the alarm call of the Red Fox-sparrow is a loud metallic "thick" or "whack". These are easily told from the notes of other species. On the other hand, the differences between many species are less striking: the Grasshopper Sparrow's call is a weak "tillic", that of the Savannah Sparrow a thin "seet" or "chip", the call of Le Conte's Sparrow a sharp "chip", junco calls a "chip" or "stip", and so on and so forth.

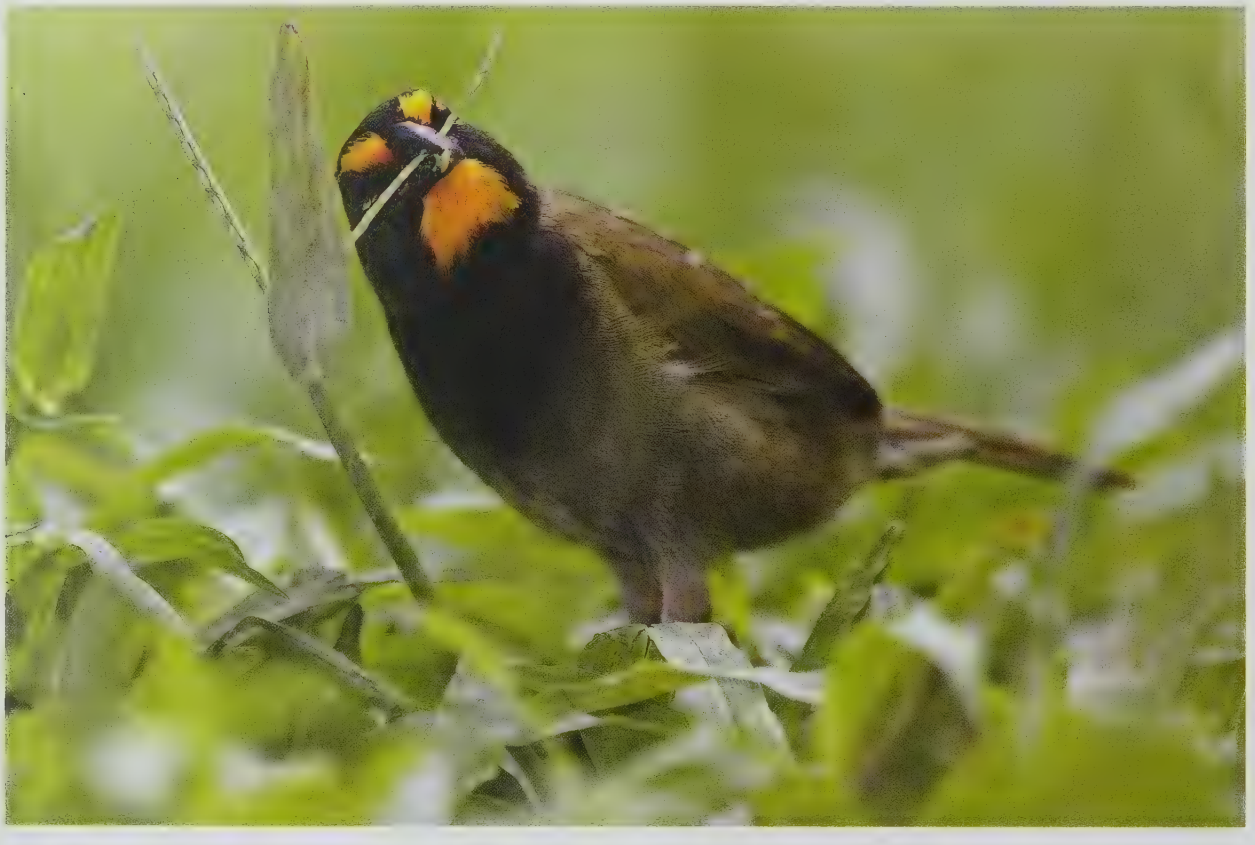
Flight calls are often distinctive, but again there are numerous vocal similarities among many members of the family. Flying longspurs have a flight note that is a whistled "wheere" or, when alarmed, a rattling "tri-ri-rip" or a staccato rattle, "tic-tic-tic-tic". With practice, the notes of the four species of longspur can be differentiated, but they are all similar to one another. In Asia, the calls of the Little Bunting and the Rustic Bunting, when flushed, are very similar, being a hard "tzick" or "pzick", but this note, used for both contact and alarm, is also indistinguishable from the calls of several other buntings, including the Chestnut-eared (*Emberiza fucata*) and Yellow-throated Buntings. Many people find the New World sparrows difficult to distinguish, but learning to identify their vocalizations can be a great help in identification. Indeed, in some instances interspecific differences in vocalizations serve as the most reliable way in which to separate species in the field. This is the case with, for example, Botteri's and Bachman's Sparrows: the ranges of these two just barely overlap, if they do at all, but the species are very different in their songs and habitat preferences. An individual outside its normal range, however, would be hard to identify with certainty unless it sang.

*The foraging **Tristram's Bunting** hops slowly on the ground, turning its head from side to side, in search of seeds and insects. Emberizids generally have a bill that is conical in shape, typical of seed-eating passerines. The upper and lower mandibles of most species are sharply angled downwards at the base, this being especially marked in* Emberiza *buntings. Larger-billed buntings can take a wider range of seeds, including large ones, but smaller species appear to compensate by selecting seeds with higher nutritional value.*

[*Emberiza tristrami*, Fuzhou, Fujian, China. Photo: Dong Lei]

Food and Feeding

Buntings and American sparrows are characteristically and typically seed-eating passerines. The conical bill, which is a defining characteristic of this family, as it is with several other groups of seed-eating birds such as the fringillid finches, the Old World sparrows (Passeridae) and some tanagers, no doubt reflecting convergence, is one of the first things that field biologists look for when trying to identify sparrows.



Indeed, seeds comprise an important component of the diet of most of the buntings and New World sparrows, but diets do change seasonally. The majority of the species feed their young with insects and other invertebrates during the nesting season, and berries and other fruits are also commonly taken as food. During the winter months, seeds account for most of the diet, but insects and berries are taken if they are available. Sparrows generally forage on the ground, picking up seeds, or searching under leaves for food, but most emberizids occasionally glean insects and other invertebrates from vegetation.

Although the conical bill is well suited for seed-eating, several grassland-dwelling sparrows, especially those living in xeric grasslands, such as Botteri's Sparrow, the Lark Bunting, the Grasshopper Sparrow, Henslow's Sparrow and McCown's Longspur, have a relatively large bill with which, in summer, they capture and process grasshoppers (Orthoptera) and other large insects. The Large-billed Sparrow, which breeds in saltmarshes in north-west Mexico, captures and eats fiddler crabs (*Uca*). Small species, such as seedeaters and grassquits in the respective genera *Sporophila*, *Volatinia* and *Tiaris*, will forage on grass seedheads while clinging to the stems of grasses, and the Lark-like Bunting (*Emberiza impetuani*) of southern Africa will jump from the ground to pull down grassheads. The Striolated Bunting (*Emberiza striolata*), found from Israel patchily southwards to north-east Africa and eastwards to north-west India, has been observed to forage in the same way, by pulling down grass stems in order to reach the seeds. Aerial flycatching is an uncommon and an unimportant method of food-gathering among these birds, although Lark Buntings fairly frequently hawk flying insects and, in the Palearctic, Crested Buntings and Corn Buntings sometimes catch flying ants in the air. When feeding on berries and other soft fruits, emberizids generally pluck these directly from the plant bearing them, but sometimes they pick them from the ground.

During the breeding season, sparrows generally forage singly or in pairs. After the young have fledged, they often form family groups, at least one parent then accompanying the fledglings for a variable period of time. Sometimes, the brood is divided between the two parents. In the non-breeding season, some species form large flocks. At this time seedeaters and grassquits sometimes gather in large aggregations of mixed composition, but during the breeding season they tend to be territorial, although they may nest locally at high density. In the Great Plains of North America, flocks containing hundreds or even thousands of longspurs are often seen in open fields and pastures during migration and in winter. In the eastern USA in winter, Lapland Longspurs, the only longspur regularly found in the east of the country, are generally present in fields near large lakes, airports or along the Atlantic coast in relatively small numbers, although occasionally in large flocks. Similarly, in England, Lapland Longspurs are found mostly along the east coast during the winter months, with fewer recorded elsewhere in that country. In southern Canada, the northern USA and central Eurasia, large flocks of Snow Buntings often gather in open country and in other open areas, such as along coastal beaches, where they feed on marram grass (*Ammophila*) or wrack, in stubble, or in other open areas not covered by snow. In agricultural areas, some species survive the winter months by feeding on seed at grain silos.

The Blue-black Grassquit feeds mainly on grass seeds. The stomach of one individual from Panama was almost completely filled with the shelled seeds of *Paspalum* and *Panicum*, which made up 98% of the contents, the other 2% consisting of the remains of ants (Formicidae) and beetles (Coleoptera). Seeds of these same grass species also form an important component of the diet of Yellow-faced Grassquits (*Tiaris olivaceus*) in Panama, and seeds of *Solanum*, *Paspalum*, pigweed (*Amaranthus*), *Panicum*, *Sporbolus*, *Carex* and *Chaetochloa* were the principal stomach contents of seven Panamanian Variable Seedeaters (*Sporophila corvina*); only one stomach of the latter contained any animal matter, a fragment of a hymenopteran.

Central American brush-finches appear to have a more varied diet. Of two stomachs of White-browed Brush-finches

Tiaris *grassquits feed extensively on seeds, particularly grass seeds, which they obtain by clinging to the stems. The family also includes a specialist on the seeding heads of bamboo, the Sooty Grassquit* (Tiaris fuliginosus). *As well as the seeds of* Paspalum *and* Panicum *grasses, the* ***Yellow-faced Grassquit*** *sometimes takes insects and berries. It also picks the tiny white protein-rich and glycogen-rich Müllerian bodies from the bases of* Cecropia *leaves. When seeds are scarce,* Tiaris *grassquits will forage high in trees, in the manner of New World warblers (Parulidae).*

[*Tiaris olivaceus pusillus*,
Valle de Antón,
Coclé, Panama.
Photo: Tom Friedel/VIREO]

A hardy sparrow, able to withstand temperatures as low as –28°C if food is available, the ***American Tree Sparrow*** *lives almost exclusively on seeds in winter, including those of pigweed* (Amaranthus), *ragweed* (Ambrosia artemisiifolia) *and beard grass* (Andropogon virginicus). *It forages on the ground, where it scratches in dried grasses, and occasionally in shrubs. It regularly visits feeders in rural areas. In the breeding season its diet can be close to 100% animal. It takes beetles (Coleoptera) and other arthropods from the ground, gleans insects from bushes and occasionally makes flycatching sallies for aerial insects.*

[*Passerella arborea arborea*, SW Ohio, USA. Photo: Dave Maslowski/ Maslowski Productions]

(*Arremon torquatus*) from Panama, one contained 45% ant material of two different species, 50% seed coverings, and 5% broken pieces of weevils (Curculionidae), whereas the other held 40% seed fragments, 30% grasshopper fragments (Acrididae) and remains of beetles (of families Calandridae, Curculionidae, Elateridae and Carabidae), and 30% hymenopteran (bee and ant) remains. Black-striped Sparrows (*Arremonops conirostris*) have a similarly mixed diet of seeds and insects, the latter including ants, beetles, lacewings (Neuroptera) and caterpillars.

Typically, Palearctic and Nearctic species that live in seasonal environments take much animal food during the summer, also feeding it to their young, and switch to a mostly plant diet in the winter. During the breeding season Lapland Longspurs feed extensively on insects, especially flies (Diptera), although they also take the seeds of grasses and low herbs. They pick invertebrates from low vegetation and sometimes from small trees, foraging as high as 2–3 m up in a tree. Furthermore, they will jump to snatch flying insects, and occasionally hawk insects. They

During the breeding season, the ***Yellow-bridled Finch*** *is found in very sparsely vegetated to grassy alpine habitats. In winter it moves down to other open habitats, including lakesides and seashores, and may mix with its congener, the Canary-winged Finch* (Melanodera melanodera), *in grassy steppes near sea-level. In early spring, pairs can be seen when foraging at the edge of melting snow in the manner of fringillid rosy-finches* (Leucosticte), *taking seeds and arthropods. Yellow-bridled Finches often feed on the petals of introduced dandelions* (Taraxacum).

[*Melanodera xanthogramma xanthogramma*, Tierra del Fuego, Argentina. Photo: Pete Morris]

The diet of the adult ***Black-headed Bunting*** *consists of seeds, including those of grasses and cereals, for much of the year. During the breeding season, when the birds generally forage singly or in pairs, they eat mostly invertebrates, which they take mainly on the ground, but also from bushes and low in trees. At the end of the breeding season they begin to congregate, and during migration are seen in flocks of 10–50 individuals. Winter flocks can be very much larger, often mixed with Red-headed Buntings* (Emberiza bruniceps), *and the two, which have very similar diets, can be found in arable fields, especially cereal stubble and fields where dung has been spread. They forage in farmyards and around grain stores only in very harsh weather, and much less so than the Yellowhammer* (E. citrinella).

[*Emberiza melanocephala*, Lesvos, Greece. Photo: Mathias Schäf]

Like grassquits, Sporophila *seedeaters feed on the seedheads of grass while clinging to the stems. The* ***Wing-barred Seedeater****, a relatively stocky seedeater with a large, short and deep bill, forages in pairs and small flocks. This species also forages in trees, taking fruits and flower buds, and possibly some insects. The Wing-barred Seedeater has been observed to feed on* Cecropia *catkins and on the protein- and glycogen-rich Müllerian bodies at the base of the petioles of* Cecropia *leaves. Outside the breeding season, some seedeater and grassquit species may gather in large mixed feeding flocks.*

[*Sporophila americana americana*, Cayenne, French Guiana. Photo: Olivier Tostain]

will feed on blowfly larvae (Calliphoridae) in animal carcasses, as well as on mosquitoes and chironomids and on lepidopteran larvae, beetles and spiders (Araneae). In the winter months, their diet consists principally of seeds, but they also take invertebrates when these become available. Young Snow Buntings are fed only with invertebrates. This species does most of its foraging on the ground. In spring and summer ice patches are important feeding areas, as large numbers of insects, carried by air currents, are left immobilized on the snow. In addition, this bunting consumes a variety of seeds and berries. In winter, eleven stomachs of Snow Buntings from Romania, in eastern Europe, contained 1322 items of plant material, of which 70% (by number) were knotweed (*Polygonum*), 13% *Celosia*, 7% *Setaria*, 7% wheat, 2% *Echinochloa* and 1% self-heal (*Prunella*); three stomachs contained some insect material, mostly grasshoppers.

Seeds account for 62% of the food taken by Dark-eyed Juncos (*Junco hyemalis*), but there is seasonal variation: in various studies, plant matter makes up 76% of the food taken during November–March, 40% in April–May, 93% in June–August, and 92% in September–October. Commonly eaten seeds include those of chickweed (*Stellaria*), pigweed, alfilaria (*Erodium*), knotweed and sorrel (*Rumex*). Grass seeds are also an important component of this species' diet. During the breeding season, Red Fox-sparrows feed extensively on beetles, fly larvae, caterpillars (Lepidoptera), ants and bees (Hymenoptera), spiders, millipedes (Diplopoda), and small molluscs, including bivalves and snails (Gastropoda), but they also eat the seeds and fruits of *Carex*, *Rubus*, *Potentilla*, *Amelanchier* and a variety of other berries. During the winter period, White-throated Sparrows (*Zonotrichia albicollis*) consume mostly small seeds and fruits, supplemented with insects when available, but in summer they feed primarily on insects, supplemented with greens and fruit.

Nectar is taken by several members of the family. Perhaps the most significant exploitation of this resource is that by the Orangequit in Jamaica, which appears to take large quantities of nectar, supplementing this with fruit of *Cecropia* and figs (*Ficus*), as well as invertebrates and seeds. This small bird has a comparatively narrow, slightly downcurved bill, which it uses also for taking tree sap at holes drilled by sapsuckers (*Sphyrapicus*). Among the other emberizids that exploit nectar as a food are the Cinnamon-breasted Bunting (*Emberiza tapahisi*), the Cinnamon-tailed Sparrow, the Grey Seedeater (*Spermophila intermedia*), the Lesser Antillean Bullfinch, the Cocos Finch (*Pinaroloxias inornata*) and some *Camarhynchus* tree-finches. The Lesser Antillean Bullfinch has been observed to rob flowers of nectar by biting a small hole at the base of the calyx.

Comparatively few details are available with regard to the diets of Neotropical emberizids. From the little that is known, it appears that they differ little from their counterparts in the Northern Hemisphere. The great majority seem to feed predominantly on seeds, with the addition of some fruits and berries. In tropical areas where there is little seasonality, or where the seasons are defined by amount of rainfall, birds of many species may adjust the timing of their breeding to coincide with seasonally available foods, such as fruits and seeds. In Costa Rica, for example, seedeaters generally do not initiate nesting until seeds are abundantly available, which is some weeks after the return of the rains, and the timing of the rains varies from year to year.

Foraging methods vary somewhat. Some species walk slowly while foraging, and then run or hop more rapidly when sighting or pursuing a food item. Some of the larger species, such as the towhees, the fox-sparrows, the *Melospiza* sparrows, the Large-footed Finch (*Pezopetes capitalis*), and some of the large *Aimophila* sparrows such as the Rusty Sparrow, search for food on the ground by using a characteristic method known as a "double-scratch", whereby the bird remains stationary while scratching backwards simultaneously with both feet. Juncos sometimes use this technique when searching in leaf litter, and in open country, when the ground is covered with snow, they will double-scratch backwards for more than 15 cm in a single effort. Savannah Sparrows and White-throated and White-crowned Sparrows, as well as juncos, hop and double-scratch, but apparently the Neotropical Rufous-collared Sparrow (*Zonotrichia capensis*), which hops, does not double-scratch. Saltmarsh Sparrows make use of the double-scratch foraging technique when searching through beach wrack; the large feet of this species seem well adapted for walking in the mud of saltmarshes, and the relatively narrow bill is used in probing into the mud for food.

Brush-finches in the genera *Atlapetes* and *Arremon* are generally found in the dense forest understorey, where they walk,

rather than run. White-browed Brush-finches and Chestnut-capped Brush-finches (*Arremon brunneinucha*) hop on the forest floor, using the bill to flick aside fallen leaves, and picking up the small invertebrates which are often concealed beneath the litter. The Orange-billed Sparrow (*Arremon aurantiirostris*) likewise forages while hopping on the forest floor, seeking food often in dark places with dense, tangled vegetation, but it apparently does not turn over leaves. Similarly, the Black-striped Sparrow hops, but does not walk, when foraging on the ground for its food of insects, small frogs and lizards, and fruits, seeds and berries. *Aimophila* sparrows usually hop when on the ground, but they will walk slowly when foraging, and sometimes run across an open area. Most *Emberiza* buntings generally hop, with the body held low, the Corn Bunting being a typical example.

An interesting adaptation is exhibited by the Reed Bunting, a polytypic species with a widespread distribution across Eurasia, its subspecies having slight differences in bill size and plumage coloration. In the winter, the large-billed races extract invertebrate larvae from inside reed stems, a foraging technique that enables them to remain all year in areas, such as western Mongolia, where the winter temperatures can drop to below minus 30°C (see also Movements).

Even those species which nest above ground, such as the Chipping Sparrow, tend to forage principally on the ground, where they move by hopping. Nevertheless, there are many species which, rather than seeking food directly on the ground, spend much of their time in perching on or clinging to stems of vegetation, especially grasses, in order to reach the seedheads. This is the commonest feeding method of most of the *Sporophila* seedeaters, for example, and is practised by many other species, ranging from buntings to grassquits. Further, many members of the family forage also in bushes and small trees, a few examples being the White-capped (*Emberiza stewarti*) and Yellow-breasted Buntings (*Emberiza aureola*) in Asia and the Golden-breasted Bunting (*Emberiza flaviventris*) in Africa. On arrival on its breeding grounds in Russia, the Yellow-breasted Bunting forages in low herbs and grass, frequently in bushes such as roses (*Rosa*), and also in larch trees (*Larix*), but rarely on bare ground. In Europe and western Asia, the Ortolan Bunting forages both on the ground and among the foliage of bushes, ascending even into the canopy of trees, especially oaks, these being particularly rich in caterpillars, an important food source for rearing the young. It also makes frequent flycatching sallies from bushes and trees. In Middle America, the Black-chested Sparrow in Mexico forages mostly in the canopy of trees, where it catches insects by foliage-gleaning in the manner of a vireo (Vireonidae) or by hover-picking, and in Costa Rica the Yellow-thighed Finch (*Pselliophorus tibialis*) often moves into the treetops to forage. Most members of the Neotropical genus *Poospiza*, the warbling-finches, are arboreal, spending much of their foraging time in trees and bushes, and many of the *Atlapetes* brush-finches tend to be more arboreal, often foraging to 5 m above the ground and sometimes climbing to 10 m. *Tiaris* grassquits will also forage at treetop height, in the manner of a parulid warbler, if seeds are scarce.

In South America, several emberizids are known to follow army ants, at least on occasion. This behaviour has been recorded for the Wedge-tailed Grass-finch (*Emberizoides herbicola*), the Great Pampa-finch (*Embernagra platensis*) and the Long-tailed Reed-finch (*Donacospiza albifrons*), and one would suspect that a number of other members of the family would associate with army ants at times.

Finally, a number of island species deserve special mention for their foraging habits. In the South Atlantic, the Gough Finch forages not only by gleaning from vegetation, including from epiphytic lichens growing on island cape myrtle trees (*Phylica arborea*) and from stems of tree-ferns, but also by using its bill and feet to pull up moss and other loose vegetation in order to expose prey, and to tear apart rotten wood; occasionally, it hawks flying insects. Moreover, it enters the breeding burrows of seabirds, and occasionally scavenges from skua (*Catharacata*) kills.

In the Galapagos Islands, in the eastern Pacific Ocean, the Woodpecker Finch (*Camarhynchus pallidus*) is highly distinctive in its foraging behaviour, which includes crawling along branches and clinging to tree trunks; this unusual finch pecks in the manner of a small woodpecker (Picidae) in order to gain access to larvae inside the timber. It is famed, however, for its ingenious and remarkable use of a tool, generally a short pointed stick, with which it pries out these larvae; observations have revealed that it will search for a short hard twig, break this to the required length, and use it as a spear with which to impale and extract concealed insect

Often perching on grass or weed stems to extract seeds which are still on the stalk, the ***Band-tailed Seedeater*** *is found on shrubby hillsides and grasslands, and also along the edges of agricultural fields and around the outskirts of towns. Generally a mountain and upland species, it may move downslope in winter. It forages on the ground and in low vegetation, with an apparent liking for the seeds of the Compositae family. The Band-tailed Seedeater has a short, conical bill as deep as it is long. Its congener the Paramo Seedeater* (Catamenia homochroa)*, a specialist on* Chusquea *bamboo seed, has a conical bill longer than it is deep.*

[*Catamenia analis analis*, Tunari National Park, Cochabamba, Bolivia. Photo: Daniel Alarcón]

The largest Darwin's finch, the ***Vegetarian Finch****, has a broad, stout bill with a strongly curved culmen, giving the bird an appearance like that of a parrot (Psittacidae). A true vegetarian, it feeds largely on leaves, flowers, buds and fruits. Of the other Darwin's finches, the warbler-finches* (Certhidea) *have a small pointed beak, like that of New World warblers (Parulidae), which they use to probe and manipulate small spiders and insects. The tree-finches* (Camarhynchus) *feed on a variety of insects, fruits and seeds, and have a triangular beak of varying depth and length for probing and gleaning. The ground-finches* (Geospiza) *are mostly granivorous and use their robust and deep bill to crush seeds. The* ***Common Cactus-finch****, however, differs from its congeners in* Geospiza *in having a long, robust, spike-like bill nearly twice as long as it is deep, with which it probes the flowers of prickly pears* (Opuntia). *These flowers account for around one-third of its diet;* Opuntia *seeds make up more than another third, and the rest consists of other small seeds, prickly pear pulp and other fruit, and a tiny proportion of arthropods. The race* intermedia *(shown here) is larger than the nominate, with a proportionately thicker and longer bill.*

[Above: *Platyspiza crassirostris*, Academy Bay, Santa Cruz, Galapagos. Photo: Tui de Roy/ Roving Tortoise Photos.

Below: *Geospiza scandens intermedia*, Santa Cruz, Galapagos. Photo: Günter Ziesler]

*The **Peg-billed Finch** has a very peculiarly shaped bill, long and fine yet thicker-based, and appearing constricted about a third of the way along. It is found in more open areas of highland forest and cloudforest, particularly with bamboo thickets. It eats mostly arthropods, but also bamboo seeds, and occasionally takes nectar, reportedly by squeezing flowers. It treats larger berries in a curious manner, piercing them with its bill and carrying them to a horizontal branch, where it squeezes the berry to obtain the juice and then discards the skin.*

[*Acanthidops bairdi*, Cerro de la Muerte, Costa Rica. Photo: Michael & Patricia Fogden]

prey. Equally renowned for its unusual behaviour is another Galapagos resident, the Sharp-beaked Ground-finch. The north-western subspecies *septentrionalis* of this ground-finch, on Darwin Island and Wolf Island, has the most extraordinary habit of drinking blood from seabirds; it pecks at the feather bases of large seabirds, often selecting a spot where a feather is growing, and then drinks the blood as it begins to flow. Apparently, this behaviour has not been recorded on other islands in the Galapagos.

Breeding

The breeding season of the Emberizidae across the Holarctic Region is generally coincident with the summer months, with a moderate degree of variation according to latitude. In the Neotropical and Afrotropical Regions, and to a large extent also in the Oriental Region, breeding is linked with the rainy seasons. In many of these areas breeding activity is at a peak towards the end of the

*Studies of the **Yellowhammer** in UK farmland during autumn and winter reveal a high consumption of cereal grain, with wheat and oats (shown here) constantly preferred over barley. The seeds of a few common agricultural weed species are also taken, in proportion to their availability and size. Yellowhammers forage almost exclusively on the ground, but are recorded also as clinging to tall foodplants, especially during snowfalls. Outside the breeding season, they feed in flocks of variable size, usually numbering tens of individuals, but occasionally hundreds. Flocks of up to 3000 have been recorded in Germany.*

[*Emberiza citrinella citrinella*, Finland. Photo: Jari Peltomäki/ AGAMI]

The end of winter and the early spring can be a lean time, with seed resources depleted and insects not yet abundant. Studies of the ***Field Sparrow*** *found that birds which bred and wintered in the same habitat patches had higher levels of fat in winter, leading to better survival, than did those which dispersed. The* ***White-throated Sparrow*** *feeds mostly on seeds and small fruits in winter, but in summer supplements its insect diet with green leaves.*

Right: *Zonotrichia albicollis*, Chicago, Illinois, USA. Photo: Rob Curtis/ The Early Birder]

main rains and often extending a little into the dry season. In regions where rainfall is lighter, or unpredictable, as, for instance in Mexico and much of sub-Saharan Africa, or in arid areas anywhere within the family's breeding range, the onset of rain normally heralds the start of breeding. In a study of Lined Seedeaters (*Sporophila lineola*) in South America, L. S. de Oliveira and colleagues found that the nesting season of this species in south-east Brazil, previously believed to cover only December to February, did in fact extend from mid-November to mid-April, a period of approximately five months. In the same region, the nesting period of the Double-collared Seedeater (*Sporophila caerulescens*) has been recorded as December–May, and the breeding seasons of the Rusty-collared Seedeater (*Sporophila collaris*) and Tawny-bellied Seedeater in north Argentina span, respectively, November to April and October to March. Thus, whereas many other birds in the region start to breed in September, at the end of the dry

The 15 species of Poospiza *warbling-finch forage at different levels and often consume quite different types of food. The* ***Black-capped Warbling-finch*** *forages largely in shrubbery, scrub and small trees. A number of other species are more arboreal. The Ringed Warbling-finch* (Poospiza torquata) *feeds largely on arthropods in the breeding season, in contrast to the sympatric Cinnamon Warbling-finch* (P. ornata)*, which relies on grass seeds. The Chestnut-breasted Mountain-finch* (P. caesar) *is more terrestrial than its congeners, foraging mostly on the ground and otherwise skulking in dense vegetation close to the ground.*

[*Poospiza melanoleuca*, Samaipata, Bolivia. Photo: Joe Tobias]

*Fruit is just one element in the diet of the **Cuban Bullfinch**, which also eats insects and seeds, and forages near the ground as well as in the canopy. Another Caribbean bullfinch, the Puerto Rican Bullfinch* (Loxigilla portoricensis), *has been observed to mandibulate mistletoe (Loranthaceae) fruit and discard the skin before swallowing the seeds. The Lesser Antillean Bullfinch* (L. noctis) *uses its foot to secure the fruits on which it feeds, stepping on the fruit to press it against the branch. Lesser Antillean Bullfinches also rob flowers of nectar by biting a small hole at the base of the calyx.*

season, *Sporophila* seedeaters appear to wait until the start of the heavy rains in November/December before beginning their breeding activities.

Most emberizids are socially monogamous. This statement should, however, be accompanied by the caveat that little or nothing is known about the mating systems of most New World sparrows and buntings, and it has generally been assumed, probably for historical reasons, that monogamy is the norm. Nonetheless, most members of this family that have been studied in depth do appear to be monogamous. In other words, the general picture at any given time has been that one male and one female appear to be associated with each other and with a nest; hence, it is reasonable to assume that they are in a monogamous relationship. Molecular methods, however, have enabled ornithologists to determine, for the relatively few species studied to date, that many nests of seemingly monogamous pairs contain young from extra-pair matings, and it may be safe to assume that both males and females of many, if not most, passerine species seek extra-pair copulations. As a result, biologists increasingly refer to species as being "socially monogamous": they appear to be monogamous, but they may well not strictly be so.

A few emberizids have been found to be polygynous, and these are discussed in more detail below.

The breeding biology of the well-studied Song Sparrow can be taken as typical of that of a north-temperate, socially monogamous breeder. Polygyny by this species is rare, but microsatellites in nuclear DNA reveal that more than 15% of 200 young were not sired by the social mate. M. M. Nice's classic studies of Song Sparrows in Ohio, in the eastern USA, have served as a model for studies of the life history of songbirds; R. F. Johnston's work with the species in San Francisco Bay, in California, and the research undertaken by J. Smith and his students on the Song Sparrows of Mandarte Island, in extreme south-west British Columbia, are other thorough studies of this species, in different parts of its range. In migratory populations, the females arrive on the breeding grounds in middle to late spring onto territories already occupied by males, which arrived earlier. In the southern part of the breeding range in eastern North America, some individuals are resident and may remain paired throughout the year; otherwise, females mate with a replacement male. In the south-west, on the saltmarshes of San Francisco Bay, where they are resident, Song Sparrows may start to breed as early as the second week of February, and on Mandarte Island nesting may take place as early as late February, whereas those birds resident in the Aleutian Islands of south-west Alaska, do not breed until mid-May. Generally, nesting is initiated later at high latitudes, but the San Francisco Bay residents may nest exceptionally early, apparently to reduce the risk of flooding by high tides.

Males are territorial, and during the egg-laying period they stay close to their mates, this being a probable instance of mate-guarding. In Ohio, the first eggs are laid from the middle to the end of April; in Ontario, in south Canada, egg-laying begins in mid-April, and in Massachusetts, in the north-east USA, it commences in very late April or early May. Clutch sizes typically range from three to five eggs, with occasional records of one or six, and are somewhat larger among migratory populations. There is some latitudinal variation in clutch size, with averages of just over three eggs for a small sample in Baja California, in north-west Mexico, just over four in Ohio, and 4·17 in Alaska; second clutches average slightly larger than first clutches. The eggs are laid at a rate of one per day. Although up to seven clutches may be produced in a single year, Song Sparrows are generally double-brooded or triple-brooded, and as many as four successful clutches have been recorded. The eggs are ovate, blue or blue-green to grey-green, generally speckled over the entire surface of the shell, perhaps with some irregular large spots at the large end of the egg. The nest, which is built by the female, is a well-constructed open cup made from dry grass, plant stems, dry leaves and strips of bark, lined with soft grasses, rootlets and sometimes hair, and is generally placed on the ground under a grass tuft or shrub. Some Alaskan populations commonly build their nests 1 m up in a conifer, and nests as high as 4 m and, rarely, 9 m above the ground have been reported.

Only females develop an incubation patch and incubate the eggs. Males rarely visit the nest during the incubation period, which lasts for 12–15 days, a typical figure being 13 days, but they may bring insects to the female on the nest. Both parents feed the young, and the male assumes a larger responsibility for the feeding of the brood once they fledge, and when the female renests. On leaving the nest, after about ten days, the young disperse throughout the territory; there is some brood division, each parent assuming responsibility for one or more young. The

Geospiza *ground-finches differ in the size and shape of their bill and in their body size, but are very similar in terms of plumage. The* ***Small Ground-finch*** *has a small and dainty bill, slightly longer than it is deep and more triangular than the bill of the* ***Medium Ground-finch****, which is more round-topped and relatively thick. The* ***Large Cactus-finch*** *has a bill which is thick yet long, while the massive bill of the* ***Large Ground-finch*** *appears as deep as its entire head. Species with a large beak can eat larger and harder seeds and fruits than species with a small beak, and tend to have a more diverse diet. The bulk of the Small Ground-finch's diet is mostly small seeds. The variety of available foods, however, influences large species more than it does small species. The Large Cactus-finch and Large Ground-finch (shown here eating a* Bursera *fruit) occur only at sites where plants producing large and hard seeds and fruits are plentiful. Thanks to its intermediate bill size, the Medium Ground-finch (here eating a* Scutia *fruit) is able to eat a more varied diet and to change its diet according to availability.*

Below right: *Geospiza magnirostris*, Genovesa, Galapagos. Photo: Mark Jones/ Roving Tortoise Photos]

*This **Wing-barred Seedeater** is feeding on the nutritious Müllerian bodies at the base of a* Cecropia *leaf. These bodies appear to have evolved to provide food for ants (Formicidae), but the insects are unlikely to be the target of the seedeater's foraging activities. When the stomach contents of seven Variable Seedeaters* (Sporophila corvina)*, a closely related species, were examined in Panama, only one contained any trace of animal matter: a fragment of a hymenopteran (bee or ant). Even nestlings of these species are fed primarily with grass seeds.*

[*Sporophila americana*, Paramaribo, Suriname. Photo: Edward Vercruysse]

young become independent of their parents at 24–30 days, and may then form loose flocks of up to 20 individuals. Young males start to sing a subsong from low perches from about mid-summer to early autumn.

Although Song Sparrows are generally monogamous, up to 21% of females and 13% of males may breed in polygamous groups. In Ohio, Nice found four bigamous males in six years, representing 2·3% of observations, and in British Columbia about 3% of the males on Mandarte Island were polygynous, with males rarely mated to three females. On one small island in British Columbia where only five adults were present, one male had four mates. Polygynous groups may form when a territorial male annexes the adjacent territory and mate of a male that has gone missing; or a female "floater" may settle on the territory of an already mated male. Males generally assist in the feeding only of the first brood to hatch, suggesting that there is selection against

*Although foraging mostly on or near the ground or low in vegetation, **McCown's Longspur** will occasionally pursue flying insects. Its relatively big bill enables it to capture quite large prey, including grasshoppers (Orthoptera) and dragonflies (Odonata). In one study in the short-grass prairies of Pawnee National Grassland, in Colorado, about a third of insect prey was captured by hawking, 14% by gleaning, and the rest by stalking. Ants (Formicidae) are another significant food item. While the young are fed with insects, the bulk of the adult diet, even during breeding, is weed, grass and cereal seeds.*

[*Rhynchophanes mccownii*, Pawnee National Grassland, Colorado, USA. Photo: Roberta Olenick/ photolibrary.com]

females joining a polygynous group. Unaided females raise about half as many young as females with male help.

The mating system of the Savannah Sparrow is similar to that of the Song Sparrow, except that in some areas males are routinely polygynous. As is typical of New World sparrows, a pair-bond is formed on the breeding grounds soon after the females arrive. The female alone builds the nest and incubates the eggs. The nest is a shallow cup of woven grasses, and is generally placed in a shallow depression in the ground, often partly covered by a canopy of dead grasses or herbs, situated at the base of a small woody shrub. Once the eggs have hatched, the male actively helps to feed and tend the chicks. When the young leave the nest, both parents may accompany the fledglings, or this may be done principally by the male, while the female lays a second clutch. In the northern part of the range, for example at Churchill, Manitoba, there may be enough time only for a single clutch, or, if the first clutch is destroyed early during incubation, a replacement clutch may be attempted. If time permits more than one clutch to be produced, however, males may become polygynous. In the Canadian Maritime Provinces, perhaps particularly on islands, such as Sable Island, in Nova Scotia, and Kent Island, in New Brunswick, the summer season is long and cool. There, while the female sits on her first set of eggs, a male may attract a second mate, which also lays a clutch of eggs. When the eggs of his first mate hatch, the male helps her to feed the young, while his second mate is incubating her eggs. When the first brood leaves the nest, the male accompanies the fledglings while this mate lays a second clutch. When the eggs of the male's second mate hatch, he will help her to feed those young as well. So, by staggering the clutches, the male can be sequentially polygynous, and still assist both of his mates in provisioning the young. On Sable Island, females can produce as many as four broods in a season, and a number of the males, varying from 5% to 47% annually, are polygynous; on Kent Island, about 20% of the males are polygynous. On the other hand, at Churchill, where the breeding season is short, polygyny, although sometimes attempted, is essentially non-existent, probably because the females are highly synchronous in their laying times, and the males cannot effectively help two different females at the same time. Apparent mate-guarding occurs, but molecular studies showed that, of seven nests on Kent Island, four contained the young of extra-pair males, and about 25% of the young are produced by extra-pair copulations.

Male Nelson's Sparrows are non-territorial and both sexes are promiscuous. During the egg-laying stage of the cycle, the female mates with several different males, and the males, in turn, mate with many different females. For the most part, the female alone incubates the eggs. Males of the closely related Saltmarsh Sparrow, on the other hand, are apparently monogamous, and the male occasionally feeds the young. Smith's Longspurs do not form any pair-bond. Breeding females of this species will mate with several different males, usually two or three, sometimes more, often copulating about seven times per hour when in the laying phase, and the males mate with more than one female. In nine of twelve nests studied, the broods were found to have mixed parenthood. A dominance hierarchy is established among the male longspurs mating with a female, and the *alpha* male fathers about 67% of the chicks. Males help to feed the young, and females, by mating with more than one male, may receive help from several different males. Rising found that males of these promiscuous species tend to have larger testes in relation to body size than those of monogamous species, which presumably reflects selection driven by sperm competition. Interestingly, agonistic interactions do not occur, or at least are rare, among promiscuous species.

Lark Buntings nest in hot, sunny areas in short-grass prairie with sparse, scattered shrubs. A shaded nest-site is an important component of a male's territory, and a male having a good territory that offers more than one suitable nest-site can sometimes attract more than a single female, especially where breeding densities are high. Co-operative breeding has rarely been recorded for emberizids, but, in one study of nine Lark Bunting nests in Utah, two had male helpers; in that population there was a surplus of males, and thus many unmated individuals.

Pair-bonds formed by the Corn Bunting are not strong. The sexes are rarely together except for sexual reasons. Corn Buntings are solitary and territorial, but their territories can be tightly clumped. Males arrive on territory a considerable time before the females. Males in a single area may be a mix of unmated, monogamous and polygynous individuals. Of 75 males in a study in Lancashire, north-west England, 72% were monogamous, 19% polygynous and 9% unmated; females were not found to be pro-

*The **Chestnut-capped Brush-finch** searches for invertebrate prey in leaf litter. It turns over leaves with its bill, but, unlike many emberizids, does not scratch with its feet. These brush-finches also glean for insects and spiders in low vegetation. They forage alone or in pairs and sometimes follow army-ant (Formicidae) swarms. Stomach contents of the White-browed Brush-finch* (Arremon torquatus), *which replaces the Chestnut-capped on higher (and sometimes lower) slopes, comprised 40–50% seeds and 50–60% insects.*

[*Arremon brunneinucha frontalis*, Bellavista Cloud Forest Reserve, Tandayapa Valley, Ecuador. Photo: Tui de Roy/ Roving Tortoise Photos]

*The bill of the tiny **Lined Seedeater**, short, thick and rounded, seems quite unsuited to catching invertebrates. But these birds, which feed largely on grass seeds, have been seen to carry caterpillars and dragonflies (Odonata) to their nestlings. This bird's target could be the spider, or perhaps insects caught in its web. Others in this group may turn to small invertebrates in the dry season, when seeds are hard to come by. Three Grey Seedeaters* (Sporophila intermedia) *made "expert" sallies of 2–4 m to catch winged termites (Isoptera) emerging from a nest, and others have been seen to sally from perches in flycatcher (Muscicapidae) style.*

[*Sporophila lineola*, Intervales State Park, Ribeirão Grande, São Paulo, Brazil. Photo: Edson Endrigo]

miscuous. On North Uist, in the Western Isles of Scotland, about 24% of males were unmated, 41% were monogamous and 33% were polygynous. There, the polygynous males generally had two females, with a maximum of three; in a study in Sussex, in southern England, however, a male was found to be consorting with up to as many as 18 females, six of them simultaneously. Female Corn Buntings may arrive in groups, and build nests. The female alone incubates, but males may help with the provisioning of the young, the male contribution varying from zero to 50%. At one nest, following the disappearance of the female four days after the young had hatched, one male fed the brood on his own, with no assistance. The broods of primary and secondary females are provisioned equally by polygynous males, and mates of polygynous males may help to feed the young of other broods.

Lekking, in the usual sense of the term, is not a characteristic of this group, but a form of it in a broad sense does perhaps occur. Several emberizid species nest at high densities, a number of different males displaying next to one another at the same time. This is true of the Lark Bunting, as well as the longspurs and the two snow buntings, and also some other open-country breeders such as Cassin's Sparrow. The Blue-black Grassquit of Middle and South America is often found at high density. The males of this little seedeater display by jumping 30–45 cm up into the air, while uttering a simple song and flashing the white patch on the underwing, before dropping down to the same perch (see Voice). The unaided human eye sees only one flash, but slow-motion photography reveals that the grassquit often flashes the underwing patch several times during the total duration of the jump. This display may be repeated every few seconds for at least half an hour.

Most members of the family sing from a perch, usually an exposed one, but many species that breed in open country have elaborate aerial displays. This is true of all of the longspurs, but especially of McCown's and the Chestnut-collared Longspurs. McCown's flies up into the air and, with slow, deep, stiff wingbeats, floats down to the ground while singing. This is very like the aerial display of the Lark-like Bunting of southern Africa and the Lark Bunting of the New World. Cassin's Sparrow, similarly, rises into the air and then sings while floating back down to earth; it will also sometimes sing from a perch on a shrub or fence post. Nelson's Sparrow, a non-territorial species, takes off, uttering "pshhh'tpt" notes, climbs to 20 m, sings, and then glides forwards and downwards, singing for a second and sometimes a third time, before dropping back into the vegetation, perhaps at a spot more than 100 m from where it started. The song of the closely related Saltmarsh Sparrow is much simpler, as also is its aerial display.

Characteristically, buntings and New World sparrows and seedeaters build an open cup-nest of woven grasses and plant fibres, rootlets and similar material. These are placed on or near the ground, often low down in a small bush, and are well concealed. Some species, such as the Rock Bunting, regularly secrete the nest in a rock crevice or some similar site. In Africa, however, it is suspected that Brown-rumped Buntings (*Emberiza affinis*) nest in cavities in termitaria, although this remains to be confirmed. Chipping Sparrows, which frequent open woodlands or woodland edge and often sing from a tree, sometimes place their nests on the ground, but more commonly they select a nest-site 1–3 m up in a bush or a small tree, and occasionally as high as 19 m above the ground.

When flushed from the nest, many sparrows perform a "rodent-run" or "broken-wing" distraction display, designed to lure the human intruder away from the nest and its surroundings. This is a common behavioural device used by many ground-nesting bird species, and is particularly well developed among the shorebirds (Charadriiformes). It is interesting that sparrows are among the comparatively few passerines to adopt the technique.

Brood parasitism of Song Sparrows by Brown-headed Cowbirds (*Molothrus ater*) is common in areas where the two co-occur. The cowbirds commonly eject the Song Sparrow's eggs, and parasitized nests produce about one fledgling fewer than non-parasitized ones. This cowbird lays in the nests of many emberizids in North America. Dark-eyed Juncos are common hosts in the south of their range, and many *Ammodramus* species and a wide range of other sparrows are parasitized at times, but the fox-sparrows are only rarely victims of the

*The **Woodpecker Finch** of the Galapagos Islands has a bill approximately twice as long as its base depth, together with strong legs and large feet. Ecologically, it fills the role of a woodpecker (Picidae) or nuthatch (Sittidae), creeping along branches and probing in bark and even in clumps of dry leaves. Like a small woodpecker, it pecks through branches and trunks to get at the larvae of wood-boring beetles (Coleoptera), and uses its long bill to lever off chunks of bark. It also makes ingenious use of a tool, usually a short pointed stick, to prise out beetle larvae. Observations have revealed that it will search for a short, hard twig or cactus spine, break it to the required length, and use it as a spear to impale and extract its prey; it usually breaks off any protruding side twigs, which would prevent the "tool" from sliding into a crevice or hole. This technique enables the Woodpecker Finch to exploit a foraging substrate which is not available to any other species of Darwin's finch. Its nearest competitor is the Large Tree-finch* (Camarhynchus psittacula), *which has a bill approximately as deep as it is long, with mandibles that cross at the tips. This species collects arthropods mainly by biting through the bark of twigs and leaf petioles, rather than, as the Woodpecker Finch does, pecking through the bark of branches and trunks. It also probes dead branches, moss and bunches of dead leaves. In the dry season, the Woodpecker Finch turns to probing moss, rather than bark.*

[*Camarhynchus pallidus*, Santa Cruz, Galapagos. Photos: Tui de Roy/ Roving Tortoise Photos]

*The **Small Ground-finch** has been observed removing ticks (Ixodoidea) from marine iguanas* (Amblyrhynchus cristatus), *Galapagos land iguanas* (Conolophus subcristatus) *and Galapagos tortoises* (Chelonoidis nigra). *This behaviour, however, varies among islands. Small Ground-finches are regularly seen cleaning land iguanas on Fernandina and on Plaza Sur (off Santa Cruz), but not a single instance was reported on Santa Fe during 5200 man-hours of observation of these reptiles. Similarly, the Medium Ground-finch* (Geospiza fortis) *cleans tortoises on Isabela, but not on Santa Cruz or Pinzón, although the finch is common on both islands.*

[*Geospiza fuliginosa*, Santiago, Galapagos. Photo: Greg Lasley/ VIREO]

cowbird. Lark Bunting nests are sometimes parasitized by Brown-headed Cowbirds, but the frequency of this is very low. The Olive Sparrow (*Arremonops rufivirgatus*) is a frequent host of the Bronzed Cowbird (*Molothrus aeneus*); most of its nests in south Texas are parasitized, to the extent that the sparrow's clutches suffer a reduction of 78%. In western North America and Mexico, both the Spotted and the Canyon Towhees are parasitized not only by the Brown-headed Cowbird, but also by the Bronzed Cowbird.

In South America, it is the Shiny Cowbird (*Molothrus bonariensis*) that is the common brood parasite. This species is known to lay in the nests of a number of emberizids, and probably parasitizes others yet to be discovered. The Common Diuca-finch (*Diuca diuca*), for example, is frequently parasitized by the Shiny Cowbird, as also is the Many-colored Chaco Finch (*Saltatricula multicolor*), while the Stripe-capped Sparrow (*Rhynchospiza strigiceps*) is occasionally victimized. In its small range in north-west Peru, the Cinereous Finch (*Piezorina cin-*

*The **Gough Finch** spends about 80% of its foraging time in searching for invertebrates, but also eats fruit and grass seeds, and scavenges broken eggs and carrion. Here, a juvenile is feeding on the carcass of a petrel (Procellariidae) killed by a skua (Stercorariidae). Gough Finches also enter seabird burrows, pull up moss and other loose vegetation with the bill or feet to expose prey, rummage in beached seaweed, and tear apart rotten wood.*

[*Rowettia goughensis*, Gough Island, Tristan da Cunha Group. Photo: Tui de Roy/ Roving Tortoise Photos]

On Darwin Island and Wolf Island, in the Galapagos Archipelago, the subspecies septentrionalis *of the* ***Sharp-beaked Ground-finch*** *drinks blood from seabirds. This race has a longer, sharper and more pointed bill than the other races, which have not developed this feeding behaviour. The* septentrionalis *finches peck at the feather bases of large seabirds such as the Masked Booby* (Sula dactylatra), *often where a feather is growing, and then "lick up" the blood as it begins to flow. The boobies do their best to dislodge the "vampire" finches. Large Cactus-finches* (Geospiza conirostris) *drink blood from already wounded booby nestlings, but do not inflict the wounds themselves. (The Galapagos Masked Boobies, incidentally, are often treated as a distinct species,* Sula granti, *the "Nazca Booby".) Sharp-beaked Ground-finches also break seabird eggs two or three times their own size by bracing themselves against them and rolling them down a slope or over a ledge, a technique used by Small Ground-finches* (G. fuliginosa) *and Large Cactus-finches when moving stones in search of arthropods. The last two species are said to capture spiders by hauling them up on their own threads, using one foot to hold down each loop of thread.*

[*Geospiza difficilis septentrionalis*, Wolf Island, Galapagos. Photos: Tui de Roy/ Roving Tortoise Photos]

Rain seeps between the strata of rock in these cliffs, before evaporating, leaving behind a deposit of salts and minerals which these ***Greater Yellow-finches*** *may be consuming. The Cinnamon-breasted Bunting* (Emberiza tahapisi) *is also known to visit saltlicks. It is possible, however, that the birds are taking advantage of the water itself, a rare commodity in the high, harsh, rocky and arid terrain where they live.*

[*Sicalis auriventris*, Reserva Provincial Auca Mahuida, Neuquén, Argentina. Photo: Darío Podestá]

erea) is heavily parasitized by this cowbird, and appears sometimes to build new lining on top of its own parasitized nest. Similarly, the Pale-headed Brush-finch (*Atlapetes pallidiceps*) is a very common host of the Shiny Cowbird; at two monitored sites, the rates of brood parasitism suffered by the brush-finch were 15%–61%, and in a 2002 study success was only 0·74 young per breeding pair.

There are no cowbirds in the Old World, but there are brood-parasitic cuckoos, and these do lay in bunting nests. This is not, however, as widespread a problem as that posed by the cowbirds in the New World. In Asia, Common Cuckoos (*Cuculus canorus*) occasionally lay their eggs in the nests of Crested and Jankowski's Buntings, and in Europe there are records of similarly parasitized nests of the Yellowhammer, Lapland Longspur, and Rock, Reed and Cirl Buntings (*Emberiza cirlus*); indeed, in Bulgaria, eight out of 90 Corn Bunting nests monitored were found to be thus parasitized. In Africa, Golden-breasted Buntings are occasionally parasitized by the Diederik Cuckoo (*Chrysococcyx caprius*) and

The ***Corn Bunting*** *drinks by filling its beak and raising its head to swallow. Corn Buntings tend to avoid the company of other bunting species, but* Emberiza *species which normally flock only with their own kind may mingle with congenerics and with fringillid finches at drinking places. The Meadow Bunting* (Emberiza cioides) *and the White-capped Bunting* (E. stewarti) *visit drinking sites first thing in the morning and again in late afternoon, but the Grey-necked Bunting* (E. buchanani) *feeds from early morning until mid-morning before flying to a water source to drink, resuming its foraging in the early evening.*

[*Emberiza calandra calandra*, Extremadura, Spain. Photo: Mathias Schäf]

*The **Black-crested Finch** is a bird of the Dry Chaco, and its congener, the Grey-crested Finch* (Lophospingus griseocristatus), *lives in even more arid desert and near-desert habitats. Emberizids show a number of adaptations for coping without fresh drinking water. Studies in Chile found that total water requirements of Rufous-collared Sparrows* (Zonotrichia capensis) *from deserts were far lower than those of the same species from more humid areas. Saltmarsh-dwelling sparrows can drink saltier water than other sparrow species can tolerate.*

Cabanis's Bunting (*Emberiza cabanisi*) by Klaas's Cuckoo (*Chrysococcyx klaas*). Otherwise, cuckoos generally appear to have little interest in buntings as potential hosts.

Movements

Most of the buntings and New World sparrows that breed in the Northern Hemisphere are migratory. In fact, all of those breeding in Canada and Alaska migrate, although a few individual Song Sparrows can be found during the winter months in southern Canada, and the subspecies *pugetensis* and *nuttalli* of the White-crowned Sparrow are resident on the west coast of North America from south-west British Columbia south to central California. Western populations of fox-sparrows move from their highland breeding grounds to the coast in winter, as do some Bell's Sparrows in California. A similar pattern prevails in the Palearctic Region, where virtually all emberizids breeding in the northern parts migrate south in the autumn, a few individuals remaining well north, and southern breeders tend to be residents. For example, the Yellowhammer is partially migratory, most of its populations displaying some migration or dispersal. All of the northernmost breeders migrate, but they generally winter within the breeding range of the species, occupying much the same habitats as those used when breeding. In southern South America, some species undertake a northward movement during the austral autumn, but most of the Neotropical members of this family are essentially resident, or wander locally or altitudinally. The Afrotropical buntings are for the most part resident or variably nomadic.

Emberizids are both nocturnal and diurnal migrants. Flocks of, for example, longspurs and snow buntings can be observed during the day as they pass through an area, generally at low altitude and quite often within 10 m of the ground, but these and other migratory members of the family certainly move at night, as well.

It is probably usual for the northernmost breeding individuals of a population to migrate farther southwards than those members of the same species that breed in the southernmost part of the range. In North America, this phenomenon, known as "leap-frog migration", has perhaps been best demonstrated in the case of the western populations of *Passerella* fox-sparrows. Fox-sparrows that breed in the Aleutian Islands and Kodiak Island, in western Alaska, migrate south to as far as south-western California; those breeding in south-central Alaska winter from south Washington south to south-western California; populations breeding from south-western Alaska to central-western British Columbia move southward to winter quarters from western Oregon south to west-central California; and fox-sparrows that breed in the Queen Charlotte Islands, off northern British Columbia, migrate south to west-central California. A similar pattern can be seen for

*The displaying male **Blue-black Grassquit** jumps vertically from a perch, flapping his wings to expose the white patch at the base of the underwing. He may jump up to 15 times in a minute, and flashes his wing patch 5–6 times in each 30–50 cm jump. Males have larger wings and a smaller body mass than the breeding female. The peak of display activity is in the morning, and a number of males may display in a cluster, similar in appearance to a lek. Unlike true lekking species, however, the males help to build the nest and feed the chicks.*

[*Volatinia jacarina jacarina*, Concepción, NW Santa Cruz, Bolivia. Photo: Daniel Alarcón]

other populations of fox-sparrows, those in the southernmost parts of the breeding range moving to the most northerly parts of the winter range.

Differences between the sexes are sometimes apparent. For example, male Dark-eyed Juncos, on average, do not winter so far south as the females, and, as with most New World sparrows, the males tend to migrate earlier in spring than the females, arriving on the nesting grounds before the females. There is apparently no difference in the wintering ranges of male and female Savannah Sparrows or in those of male and female White-crowned Sparrows, and, because these species exhibit no sexual plumage dimorphism, it is difficult to determine whether there are any differences between the sexes in the timing of migratory movements.

In general, individual sparrows breeding at high elevations descend to lower levels in the winter, and some perhaps move southwards or, in the Southern Hemisphere, northwards, as well. Although the proximal cues to migration appear to be changes in the photoperiod, the ultimate reason for such movements is the need to have access to food. Most sparrows feed extensively on the ground, but, if the ground is snow-covered, they cannot get to their food, and as a consequence they migrate to regions with a more reliable food supply. Food, rather than temperature, seems to be the important factor to them, as well as to most other songbirds. In North America, many sparrows do not generally migrate farther south than southern Pennsylvania, Missouri and areas at similar latitude, where there is generally some ground that is not covered by snow during the winter; few fly south of central Mexico.

The Lark Bunting is a good example of a migratory North American emberizid. It breeds from south Canada southwards through the Great Plains of the USA, and it migrates to non-breeding grounds in the southern states and into the northern half of Mexico. After breeding, the adult males migrate earlier than the females or young, and the adult females appear to move south earlier than the juveniles. Although migrants are found from July, sometimes in good numbers, in southern Arizona, the species does not leave its south Canadian breeding grounds until late July and early August, which suggests that the northern populations migrate later than those farther south. In south-west Texas, passage of this species reaches a peak in early September, and in much of the breeding range migration has finished by the end of that month. Lark Buntings arrive on wintering grounds in northern Mexico by early August, larger flocks becoming more prominent by mid-August. Departure from the Mexican wintering grounds begins as early as February, but some remain in Sonora into April or even, rarely, May. The earliest migrants reach Texas in early March, but passage numbers do not increase until late April, reaching a peak in the first two weeks of May. The first individuals arrive at the northern edge of the range in late May, males approximately a week ahead of the females. Vagrants of this species are observed on both coasts in both seasons, on the west coast more often in autumn.

American sparrows are not normally long-distance migrants, and are generally scarce on the islands of the Caribbean. In contrast, many of the buntings of Europe and Asia are true long-distance migrants, some of them undertaking exceptionally long flights to and from their breeding grounds in the north of the region. Some of these movements are detailed in the following paragraphs.

One well-known example of a long-distance migrant is the Ortolan Bunting. This attractive species breeds from Fennoscandia and Germany eastwards in Asia to central Mongolia, and, in the south, from Iberia east very patchily to north Iran and south Turkmenistan. The entire population, after breeding, migrates to the northern part of sub-Saharan Africa. Most depart during the period from mid-August to mid-September, more northerly breeders often earlier, from July. Individuals that breed in western Europe probably move across the Strait of Gibraltar and along the coast of north-west Africa, and their non-breeding quarters are thought to be in the mountain ranges of Sierra Leone and Guinea, with a likely extension eastwards to Nigeria. Ortolan Buntings breeding in eastern Europe and in Asia fly around the eastern end of the Mediterranean Sea and then proceed southwards to wintering grounds in the highlands of Ethiopia, Eritrea and, probably, adjacent southern Sudan and north Yemen. Unfortunately, rather little is known of this species' non-breeding range in Africa, and the possibility that it winters right across the Sahel region requires investigation. Flocks arrive in West Africa mainly during October and November; arrival in central

*Female emberizids solicit copulation by raising the tail and fluttering the slightly drooped wings, calling as they do so. While many birds in northern Argentina start to breed in September, at the end of the dry season, the **Tawny-bellied Seedeater** waits until the start of the heavy rains in November/ December. The female **Yellowhammer** prefers to copulate with older, more colourful males. Of 123 Yellowhammer nestlings, 37% were found to have been sired by an extra-pair male.*

Right: *Emberiza citrinella citrinella*, Laspaules, Huesca, Spain. Photo: Rodrigo Pérez Grijalbo]

In the USA, the ***Rufous-crowned Sparrow*** *breeds in late winter and spring in California, but in summer in south-western deserts, following the rains. The female alone builds the nest, which is a bulky cup made largely from dry grass, with a lining including finer grass and animal hair. The nest is usually placed on the ground and well hidden, often by overhanging grass, at the base of a bush or on a rocky slope. More rarely, it can be placed up to 45 cm above the ground in a shrub. Nest-sites may be reused for many years. Surveys during the non-breeding season found that these sparrows stayed paired and on territories throughout the year. During periods of food scarcity, following low rainfall, Rufous-crowned Sparrows may shorten or abandon their breeding efforts. They are typically single-brooded, although pairs in California have been seen to raise two and even three broods. Similarly, the nest of the* ***Lapland Longspur*** *is built by the female. A cup of dry grass, leaves and moss is lined with hair and feathers, in particular ptarmigan* (Lagopus) *feathers. It is placed on the ground, concealed by vegetation or a tipped rock. The male guards his sexually receptive mate for about ten days, during which period he is highly aggressive towards other males which intrude into the nest area. Once incubation begins, however, he becomes tolerant of other males.*

[Above: *Aimophila ruficeps eremoeca*, Guadalupe Mts National Park, Texas, USA. Photo: Rick & Nora Bowers/ VIREO.

Below: *Calcarius lapponicus lapponicus*, Norway. Photo: Markus Varesvuo]

*The nest of the **Double-collared Seedeater** is a cup less than 7 cm in diameter and 5 cm in height, made from dry grass roots and spider webs. The walls are so thin that the eggs and young can be seen through the sides. These seedeaters seem not to favour any particular plants for nest construction. In a study of 41 nests, 18 plant species belonging to eleven plant families were used. The nests are placed an average of 2·4 m from the ground, though often less than 50 cm and sometimes as high as 6 m, in a shrub, small tree or lower vegetation.*

[*Sporophila caerulescens caerulescens*, Ubatuba, São Paulo, SE Brazil. Photo: Ivan Sazima]

Ethiopia is in early October. Migration studies in south-east Kazakhstan indicated that first-year individuals pass through before the adults, the passage reaching a peak in numbers in early September.

The return passage in spring is more conspicuous than the autumn movement. Flocks of variable size move through the western Mediterranean region from late March until the middle of May, the greatest numbers in the first half of April, and large numbers pass through the eastern Mediterranean at about the same time. The birds do not reach the far north of the breeding grounds until the second half of May and the early part of June. In areas of the Middle East, the spring passage can sometimes be very striking. In March and April, numerous loose flocks of Ortolan Buntings make their way northwards at low level, briefly taking shelter from the heat by pausing in the scattered desert shrubs, or feeding on whatever is available. These flocks are sometimes accompanied by somewhat smaller numbers of Cretzschmar's Buntings (*Emberiza caesia*), a species having a much less exten-

*There is no information on the breeding of the **Red-cowled Cardinal**, but the nest appears similar to that described for the Red-crested Cardinal* (Paroaria coronata)*, with which the Red-cowled may form a superspecies. The nest is cup-shaped, made from fibres and fine stems, and lined with rootlets and hair. Male and female Red-crested Cardinals are reported as remaining in continuous contact through vocalizations while breeding. Several* Paroaria *species favour lakeside or riverside habitats, and their nests are sometimes placed in trees or shrubs overhanging water, or in swamps.*

[*Paroaria dominicana*, Alagoas, Brazil. Photo: Anita Studer]

*The **Grassland Sparrow** is found in a variety of grassland habitats, from dry* cerrado *to* pampas *and pastures which are moist enough to have sedges (Cyperaceae). The nest, of dry grass, is placed on the ground, with a runway leading to it through the grass. Sometimes grass grows over the runway, creating a loosely covered tunnel. The nest itself is usually described as cup-shaped, although it is possible that it is sometimes roofed over.*

[*Ammodramus humeralis humeralis*, Alagoas, Brazil. Photo: Anita Studer]

sive breeding range confined to the southernmost part of the Balkan Peninsula eastwards to southern Turkey and the Levant. Despite the fact that this region has a relatively hospitable winter climate, Cretzschmar's Bunting migrates south to north-east Africa, having winter quarters mainly in Sudan.

Many other Palearctic buntings migrate long distances between their breeding and non-breeding grounds. The Black-faced Bunting (*Emberiza spodocephala*), for example, breeds in eastern Asia from about central Siberia east to Japan, with an isolated population in east-central China. It appears to be almost entirely migratory, most of the northern population flying south in autumn to south and east China, and the southern population moving to winter grounds in the foothills and lowlands from Nepal east to north Vietnam. It is rather remarkable that this east Asian species has been recorded on a number of occasions as a vagrant in western Europe as far west as Britain and France, although the possibility that some of the individuals were of captive origin cannot be ruled out. The same could be said of the Red-headed

*In the south and east of its range, the **Saffron Finch** regularly builds its nest inside the clay "oven" nest of the Rufous Hornero* (Furnarius rufus). *In Trinidad, it almost always uses the abandoned nests of the Yellow Oriole* (Icterus nigrogularis). *Artificial sites such as pipes or light fittings may also be used. The Saffron Finch's own nest is a bulky half-sphere of dry grasses, lined with softer material, including hair. Many* Sicalis *yellow-finches are cavity-nesters and will occupy kingfisher (Alcedinidae) tunnels in banks, or nest-holes made in cacti by woodpeckers (Picidae). Some excavate their own burrows.*

[*Sicalis flaveola pelzelni*, Porto Alegre, Brazil. Photo: Adriano Becker]

*The nest of the **Small Ground-finch**, a sphere with an entrance in its side, is built by the male from dry grasses and other vegetation. A study of contiguous populations of Small Ground-finches in lowland and highland habitats on Santa Cruz found that the highland birds had smaller clutch sizes and a shorter renesting interval. The highland population suffered much higher levels of nest predation, and its incubation sessions were longer, probably to reduce the number of visits to the nest and thus lower the risk of drawing the attention of predators.*

[*Geospiza fuliginosa*, Bartolomé, Galapagos. Photo: Tui de Roy/ Roving Tortoise Photos]

Bunting (*Emberiza bruniceps*), which breeds from the region of the Caspian Sea east to north-west China and western Mongolia and migrates to India. This bunting has been recorded several times on the east coast of Asia, including Japan, and, in the opposite direction, it has been found in many European countries, including Iceland. Although the records in Europe have long been considered to have involved escaped captives, a recent analysis of records in Britain, France and Italy suggests that at least some, especially those of first-winter individuals in autumn, may well refer to genuine vagrants.

Perhaps the most impressive migrant of all among the Eurasian buntings, however, is the Rustic Bunting. This handsome emberizid has a breeding range extending from Fennoscandia eastwards across Siberia to Kamchatka. Apart from a small number of individuals which spend the winter in the area of the Tien Shan in south Kazakhstan and north-west China, the entire

*The female **Savannah Sparrow** chooses the nest-site, often at the edge of or outside the male's territory. She builds the nest and incubates the eggs alone. Clutch size is 2–6 eggs, usually 4–5, and on average slightly larger at higher latitudes. The incubation period varies from nine to 15 days, but is generally around twelve days. Studies have found that yearling and older females are equally efficient incubators, suggesting that this behaviour is innate. Male Savannah Sparrows can be polygynous and may find successive mates while the earlier ones are sitting. As timing of clutches is staggered, the male can assist with the feeding of each brood.*

[*Passerculus sandwichensis sandwichensis*, Manitoba, Canada. Photo: George K. Peck]

population of the Rustic Bunting migrates to wintering grounds in east China, Korea and Japan. It seems that those breeding in north-west Europe initially head eastwards, following the southern edge of the taiga, to east Siberia, where they turn and proceed southwards through eastern Mongolia and north-east China. This journey covers a distance of 8000–9000 km or more. The Rustic Bunting has been recorded as accidental, a straggler or a vagrant in many places, and is regularly seen in several countries of western Europe and, more surprisingly, in parts of the Middle East, especially Israel. It has also been recorded on the east coast of the Pacific Ocean from Alaska and south-west Canada south to California.

The Reed Bunting presents a somewhat complicated picture. Its northern populations, those breeding from Fennoscandia south to Ukraine and east to north-east Russia and Japan, are, predictably, migratory, whereas other populations are largely resident or make only local movements. In the western part of the species European range, however, those breeding in areas where the mean January temperature is below 0°C are normally migratory, whereas individuals breeding in regions where the corresponding temperature is around 5°C are mostly sedentary. This may again suggest that, rather than the temperature itself, it is the likelihood of snowfall and a consequent lack of access to seeds on the ground that prompts the buntings to move. This is corroborated by the fact that, in the northern Black Sea region and in Central Asia, where precipitation is less common, the average winter temperature is below freezing but the Reed Buntings remain there during the winter. In this connection, it is worth remembering that the large-billed subspecies of this bunting, such as *pyrrhuloides* in Mongolia, are able to survive in winter temperatures of below minus 30°C, as their extra-large bill enables them to extract larvae from inside reed stems (see Food and Feeding).

Although most South American sparrows are resident, the southernmost populations of some tend to move northwards for the winter. For example, the widespread Rufous-collared Sparrow is resident in most areas of its range, but its southernmost subspecies, the Patagonian *australis*, migrates north in May, after breeding, returning south again in September. The whereabouts of its non-breeding grounds are not known, but it is thought to move north to as far as Bolivia.

The Cinnamon Warbling-finch (*Poospiza ornata*) breeds in central Argentina from San Juan and La Rioja south to north La Pampa and west Buenos Aires. It is a partial migrant, some individuals making post-breeding movements north to Salta, Tucumán, Córdoba and north Buenos Aires. Breeding by this species varies from year to year, being dependent on local rainfall patterns, and its breeding distribution is therefore changeable. Nevertheless, all leave east Mendoza during the autumn and winter, presumably heading northwards. They arrive back in spring and numbers increase during the summer; if the available seed supply is sufficient, the species breeds, but in dry years it may arrive in spring and then abandon the area for other possible breeding sites.

Buntings in the Afrotropical Region tend to be somewhat nomadic, the movements being governed by rainfall. The widespread Cinnamon-breasted Bunting is not only locally nomadic, but also a partial migrant and a resident. Populations in West Africa move north in the rainy season and south in the dry season. Similar movements occur in southern Africa, where populations breed in both areas: in Botswana and Zimbabwe the species is mainly a summer visitor, in December–March, but in Zambia and Malawi its numbers reach a peak in April–September, after the rains. The Lark-like Bunting is found only in southern Africa, south from southern Angola, and is generally nomadic. It migrates into more mesic parts of the Western Cape of South Africa to breed, arriving there after the winter rains have ended. Droughts can cause it to make irruptive movements into areas well to the north and east of its normal range. Drought conditions will also force Cabanis's Buntings to move, but in this case the birds shift only for short distances, the species being largely resident. Much the same applies to the Golden-breasted Bunting, which sometimes wanders in small flocks outside the breeding season, and may abandon areas during drought; this species may make a regular mid-summer movement into north Botswana from farther south, but further study is required in order to confirm this. The poorly known Somali Bunting (*Emberiza poliopleura*) is thought to be primarily resident, but the possibility of some local movement is indicated by the fact that it is occasionally attracted to lights at night in Kenya, and by an extralimital record in north-central Tanzania.

Evidence suggests that, as with its congener the Slaty Finch (Haplospiza rustica)*, the breeding of the* ***Uniform Finch*** *may be linked to bamboo seeding events. At other times, Slaty Finches are usually seen alone or in small groups on highland pastures where grasses are seeding, with no evidence of breeding. These two species may form a superspecies and have been proposed as conspecific, but they differ in their nest architecture. The Uniform Finch builds a cup-shaped nest, while that of the Slaty Finch is an elongate globe open at the side.*

[*Haplospiza unicolor*, Itatiaia, Rio de Janeiro, SE Brazil. Photo: Ivan Sazima]

*The bulky oven-shaped nest of the **Black-striped Sparrow** is built entirely by the female. The inclusion of large, coarse vegetation such as banana leaves may, in the rainy parts of this bird's range, keep the nestlings from becoming wet and chilled. The usual clutch is of two eggs, rarely one or three, and the female incubates them for 13–14 days. Darwin's finches, such as the **Small Ground-finch**, typically begin breeding 1–2 weeks after the first heavy rains; in years with no rain, breeding is forgone. The clutch is usually of four eggs.*

Finally, when talking about the migration of buntings and longspurs, it is impossible not to recount the details of an extraordinary event that took place in March 1904 in the northern USA. In the middle of that month, reports were received from villages of Worthington and Slayton, in south-west Minnesota, that large numbers of a small brown bird had been killed during a violent storm on the night of 13th–14th March. A couple of days later, several corpses were sent to the State University at Minneapolis, which forwarded them to a local ornithologist; the birds were Lapland Longspurs. Following a telephone call to one of the towns, L. O. Dart, representing the State Natural History Survey, visited Worthington and Slayton to investigate; he studied the numbers and distribution of the dead birds and the post-mortem findings, and interviewed various residents who had witnessed the event. He visited several other places, too. A few days later, letters requesting further information were sent to the postmasters at 23 villages in south-west Minnesota, north-west Iowa and south-east South Dakota, and ten replies were received. Most of the people in the towns in question were eager to tell what they had seen and to find out what had caused what they termed "the great bird shower".

Starting on 22nd March, Dart found large numbers of dead longspurs in all the streets of Worthington, and many had already been washed away by a rainstorm on 20th. There were dead birds lying 1·5–2 m apart all over the courthouse yard, and this was said to have been the situation throughout the town on the morning after the storm. The town is flanked by two small lakes, each with a minimum area of 260 ha; winter ice was still on the lakes, but the snow had melted and then frozen again, presenting an unobstructed hard surface. Here, the dead birds were more conspicuous, and their bodies dotted the entire surface of both lakes. Dart walked out to the middle of each lake and, by measuring off a number of squares 20 feet × 20 feet (c. 6 × 6 m) in various places and counting the birds in each, was able to make a careful estimate of the total number. The figures produced a total of 374,328 birds on each lake, giving the remarkable round-figure total of 750,000 Lapland Longspurs on these two lakes alone. In addition, many live longspurs, with various injuries, were present in bushes around one of these lakes; some could not fly properly and could be picked up. These had apparently managed to survive since the storm in this sheltered, unnatural habitat. Moreover, two live longspurs, a male and a female, were seen among plants in a town windowbox, where they had been fed since being captured on 14th. From interviews at Worthington, it was apparent that on the night of 13th–14th March there was almost no wind and snow was falling steadily and quietly for part of the night; the longspurs were first noticed at about 23:00 hours, and from then until morning they were abundant; they were most numerous in the vicinity of the electric streetlamps, but "they seemed to be everywhere". One witness saw many fly against buildings and he picked them up dead, as well as hearing others crashing and dropping in the darkness. He said that the ground was in places covered with dead, wounded and apparently unhurt birds. A great many lay buried in the snow with just the head out, and some of these, when picked up, warmed and dried, flew away evidently unharmed; these appeared to him to be "bewildered" more than injured. Another witness said that at midnight the air had been full of birds, but there were more around the electric lights than elsewhere; many were captured and examined. Some, uninjured, lay in the snow and made no effort to escape. The feathers of many were soaked from the wet snow. The pathways and streets were covered with dead and live birds. Another resident reported that, on the morning after the storm, he noticed balls of snow on the roof of his barn. When these thawed in the morning sun, they were found to contain live birds; the heads appeared first, and then, shaking off the snow, the birds sat for a while in the sun, drying off and preening, before flying off. This was corroborated by a second observer. Evidently, the birds had become laden with snow, and through their efforts to rid themselves of this had rolled themselves into snowballs. Two Worthington physicians gave similar accounts, one adding that many of the birds had entered the snow head first, as though they had dived headlong, rather than fluttering down as would be likely after striking an obstacle. Dart found the situation in Slayton, some 40 km to the north of Worthington, to be very much the same; on 23rd March, nine days after the storm, dead birds were to be found everywhere, their heads, wings and tails sticking out of the mud on every street right to the outskirts of the town. The same story was repeated at other villages and towns up to 50 km from Worthington.

*The male **Cape Bunting** accompanies the female as she builds the nest, and feeds her as she incubates. In most* Emberiza *species the female incubates alone, but there are some exceptions. For example, both sexes of the Little* (Emberiza pusilla), *Rustic* (E. rustica) *and Reed Buntings* (E. schoeniclus) *incubate, although the male, which does not develop a brood patch, tends to sit for shorter stints. A male Grey-necked Bunting* (E. buchanani) *with a brood patch has been reported.*

[*Emberiza capensis capensis*, near Brandvlei, Northern Cape, South Africa. Photo: Nico Myburgh]

The results of numerous post-mortem examinations of individuals from all parts of the region were uniform: all had died from injuries of various kinds. In addition to 150 or so longspurs examined carefully in the field, 100 individuals picked up on the ice and around the village at Worthington were taken home for detailed autopsy. Many had the skull fractured and indented, leading to cerebral haemorrhage, and many more had the bones of the body variously crushed, along with extensive internal haemorrhages; in some instances the intestines, lungs or other viscera had been ruptured, and a few had the neck broken. Many also had broken wings and legs. All were very fat, and the stomachs of many were empty except for, usually, small amounts of fine gravel.

It is very clear that, on that fateful night, a huge migratory movement of Lapland Longspurs was in progress. Presumably becoming confused in the storm area by the darkness and heavy

*These **Golden-breasted Bunting** chicks are three days old and are being brooded by the female. The male feeds her while she is incubating and may continue to feed her while she broods. Both sexes feed the chicks and defend the brood vigorously, the male occasionally performing distraction displays to lure predators from the nest.* Emberiza *hatchlings are covered in grey down. In India, Striolated Buntings* (Emberiza striolata) *were brooded intensively but not fed on their first day; they were fed with regurgitated seeds from the second day until the ninth, when the parents began to bring them caterpillars. After the switch to insects, their weight tripled in just five days.*

[*Emberiza flaviventris flaviventris*, Stone Hills Game Sanctuary, Zimbabwe. Photo: J. R. Peek]

*Like other Neotropical passerines, the **Black-striped Sparrow** has longer incubation and nestling periods, up to 15 days and 14 days, respectively, than relatives from temperate regions. The chicks are fed by both parents. They are covered with natal down when they hatch, and by three days of age their wing feathers have started to break the skin; their eyes open at three days. This brood of three is said to be unusual; two is more typical in Costa Rica. The Green-backed Sparrow* (Arremonops chloronotus), *sometimes treated as conspecific with the Black-striped Sparrow, has broods of three and occasionally four. The juvenile plumage of these species differs significantly.*

[*Arremonops conirostris richmondi*,
Costa Rica.
Photo: Marco Saborío]

falling snow, they were attracted by the lights of the towns below and gathered in immense numbers over and around these places. In their bewilderment, great numbers of them flew against various obstacles and were stunned or killed, and many others sank, exhausted, to the ground. Moreover, a significant number probably became wet and snow-laden by reason of the nature of the snow and, unable to fly, were forced earthwards and dashed to death, or, if dropping from a lower elevation, stunned. The birds picked up on the ice had equally extensive injuries, and in their utter confusion they must have dashed headlong on to the lake surface from a considerable height. That the birds fell heavily or sped rapidly downwards from high in the air would seem to be the only explanation for the badly mutilated condition of the dead longspurs on the ice of the lakes. Many dead birds found in yards and fields and on roofs of buildings appeared to have been killed in the same manner.

*Both **Rock Bunting** parents feed the nestlings; this is the male. The 3–6 young are fed with insects, and particularly caterpillars. Older nestlings may also be offered seeds. The nestling period is 9–13 days and the young leave the nest before being able to fly, becoming independent three weeks later. The parents often begin a second brood about a week after the first one has fledged. Exceptionally, there may be a third brood, though reportedly more often in north Africa, where eggs may be laid from January to October and where the population is non-migratory.*

[*Emberiza cia cia*,
Huidobro, Burgos, Spain.
Photo: Joseba del Villar]

Analysis of faecal samples from ***Yellowhammer*** *nestlings on UK farmland in successive years found that unripe cereal grain was fed to most broods. Adult faecal samples held only cereal husk, but invertebrates—including spiders, butterfly and moth larvae, beetles and flies—were the major component of the nestling diet. Aphids may be fed to nestlings, and the proportion of hoverfly larvae (Syrphidae), which are aphid predators, rises in years when aphids are abundant. Increased nest failure in cold summers is likely due to the competing needs of brooding and foraging: nestlings chill faster and invertebrates are less active and harder to find.*

[*Emberiza citrinella citrinella*, Gallangos, Burgos, Spain. Photo: Joseba del Villar]

It is impossible to calculate the number of Lapland Longspurs killed in that single catastrophic event in March 1904. Even one hundred years later, with the great advances in technology made since that time, one would have difficulty in assessing a similar event. The destruction seems to have been greatest at Worthington, where, on the basis of the accurate calculation of mortality at the lake surfaces alone, a figure of about 1,500,000 deaths would be reasonable. Although there seem not to have been so many victims at other points, the grand total of deaths over the whole affected area of almost 4000 km² must have been colossal. What is even more remarkable perhaps is that all of the birds were Lapland Longspurs; not a single individual of any other bird species was found dead. It is interesting to consider also that, if the global population of the Lapland Longspur was 150,000,000, as thought at present, the massive mortality on that one night would represent a loss of 1% of the species' total numbers.

Relationship with Man

Species in the family Emberizidae are of comparatively little commercial interest to humans, with the exception of the perceived value of some as cagebirds. In addition, some are trapped and sold as food. In general, they are not disliked for any particular reason, and they are looked upon kindly by most humans. In the Caribbean region, where many birds are given a variety of colloquial names, the Orangequit, restricted to Jamaica, is known there also under the names of "Blue Baize", "Swee", "Long-month Bluequit", "Bluebird", "Blue Badas" and "Blue Gay"; on the same island, the introduced Saffron Finch (*Sicalis flaveola*) is referred to also as the "Canary". In Chile, the hooded sierra-finches are commonly referred to by the name "*cometocino*", which means "bacon-eater"; this is particularly applicable to the Patagonian Sierra-finch (*Phrygilus patagonicus*), well known for its habit of eating meat left out to dry in the sun.

In the USA, the fact that the Lark Bunting is the state bird of Colorado would imply that it is not unpopular there. Elsewhere in the world, the Yellowhammer and the Cirl Bunting are among the species introduced in New Zealand by colonists from Europe, perhaps a measure of the popularity of these birds. In Switzerland, the Cirl Bunting is a characteristic bird of vineyards. Its distribution in that country coincides extensively with that of wine-producing areas, as a result of the sunny, dry habitat, the open undergrowth, the rich structure of the vegetation, and the close interweaving of the most varied environmental elements such as vines, impoverished meadows, hedges, fruit trees and dry-stone walls.

Many members of the family are kept in captivity to some degree, and some are particularly popular because of their attractive plumage and, in some cases, pleasant songs. The Yellow Cardinal (*Gubernatrix cristata*) of Uruguay and northern and eastern Argentina is valued as a cagebird because it is pretty and has a song that is pleasing to humans, and this Endangered species has consequently been overexploited in much of its range. *Paroaria* cardinals are commonly trapped for the cagebird trade too, the Red-crested Cardinal (*Paroaria coronata*) being a good example, but this practice appears not to have had any significant effect on their numbers. In the Neotropics, the yellow-finches and the seedeaters and seed-finches are especially popular as cagebirds. The Saffron Finch is widely kept in captivity, as is the Grassland Yellow-finch (*Sicalis luteola*), and it seems that the populations of these emberizids can withstand the losses. The same cannot be said about the seedeaters, many of which are popular in captivity and several of which have suffered badly as a result. The Buffy-fronted Seedeater (*Sporophila frontalis*), Temminck's Seedeater (*Sporophila falcirostris*), Marsh Seedeater and Chestnut Seedeater are all globally threatened, largely or partly because of the effects of trapping (see Status and Conservation). The Marsh Seedeater is particularly favoured by bird-collectors because of its unique coloration.

Similarly, the seed-finches in the genus *Oryzoborus* are popular as cagebirds, and the Large-billed Seed-finch (*Oryzoborus crassirostris*) has suffered a great reduction in its numbers as a consequence of trapping. This species is now very local and scarce in most of its range, increasingly so in the Guianas, where trapping is most severe. Almost all of the Old World buntings, and especially the more colourful ones, are popular in the cagebird trade. In the past, the globally threatened Japanese Yellow Bunting (*Emberiza sulphurata*) was widely trapped in Japan, and this was partly responsible for its decline.

Most emberizids are largely granivorous, and this makes them easier to keep in captivity than insectivorous species. Many,

however, are rather drab in appearance, and there is therefore a lack of interest in keeping these as pets.

A problem not often appreciated by cagebird-fanciers is one posed by captive birds that return to the wild. In addition to possible ecological implications, individuals that escape from captivity, or are deliberately released, can cause problems for ornithological records. Many buntings and New World sparrows are migratory, and some are prone to vagrancy. In some instances, however, it has proven impossible to determine whether an emberizid seen a long way outside its normal range is a genuine vagrant or has escaped from captivity.

On the subject of vagrancy, a heart-warming episode concerns a White-crowned Sparrow that turned up in eastern England in January 2008, having come 4800 km across the Atlantic Ocean. It appeared at Cley Next the Sea, on the coast of Norfolk, and before long thousands of "twitchers" and other bird enthusiasts had made their way to the village. This was only the fourth record of the species in Britain. It has become the traditional practice at such big birding events to make a charity collection, to which all visiting observers are expected to contribute, as a way of thanking the owners of sites for their patience and understanding. In this instance, as the sparrow spent the first weeks of its stay in the garden of a retired vicar, it was decided to hold a collection to help towards the restoration of the window in the village's thirteenth-century church. In fact, the collection raised £6378, sufficient to pay the entire costs for restoration of the west window. In return, the Church of England authorities gave special consent for an image of the bird to be incorporated in the new window, and this now includes a life-size representation of the sparrow, painted by a local bird artist. The White-crowned Sparrow is thought to have been blown off course while migrating southwards from the east coast of Canada. Alternatively, it may have hitched a ride to Europe on a ship.

Emberizids are generally not eaten by people, although there are some important exceptions. In parts of Europe, the Ortolan Bunting is considered a delicacy. In France, in particular, these birds are captured and fattened up, and then drowned in Armagnac, before being roasted and served whole, the bones, as well as the flesh, being eaten. This bunting is said to symbolize the French soul, and many people in south-west France believed it to be the highest of all cuisine. Indeed, it is considered such a delicacy that the former French president, François Mitterand, had it as his last meal, an illegal act as the species, much reduced in numbers, is now protected. The culinary renown of this bunting is such that in several countries of southern Europe the name "ortolan" is often attached to any passerine caught for the pot.

Buntings in south and east Asia have traditionally been captured for food, often in large quantity. Yellow-breasted Buntings, which breed across much of the north Palearctic, migrate to south-eastern Asia; many pass through eastern China, where they have long been trapped in very large numbers, a practice known to date back at least 2100 years. In recent times, hundreds of thousands of these buntings are known to have been caught each autumn, mainly in October and November, and then sold at markets. The practice was banned in 1997, but it still persists on a large scale, especially in the south-east province of Guangdong, and also elsewhere in China. It is estimated that 1,000,000 Yellow-breasted Buntings are sold for food each year. Elsewhere in the region, thousands of buntings were killed for food during the spring migration in the 1950s and 1960s. In Cambodia and Thailand, trapping for food continues, and the birds are caught also for later release as part of religious festivals. In addition, each year, in China, thousands of male Yellow-breasted Buntings are killed, stuffed and sold as mascots, their presence in the home being believed to bring happiness to the human occupants.

In the north Nearctic, the Copper Inuit, or Kitlinermiut, a Canadian Inuit group living north of the tree-line in northern Northwest Territories and west Nunavut, included Snow Buntings as part of their diet. The tameness of these birds would have made them easy to catch. Right across the Arctic, the Inuit peoples have, for thousands of years, told of the great shaman Kiviuq, one of Canada's great heroes and, according to most elders, still alive today. Among the helping spirits that Kiviuq has is the little Snow Bunting, as well as the huge polar bear (*Ursus maritimus*) and other animals.

Of course, the importance of the Galapagos finches in inspiring Charles Darwin's theory on evolution by natural selection is well known. In September 1835, when Darwin first went ashore in the Galapagos Islands, he was about to change the world's ideas on science and evolution, although he was not aware of this at the time. During the five weeks which he spent on the

*Both **Eastern Towhee** parents feed the nestlings, but their responsibilities can change over the season. Females may begin a second nest 1–2 weeks after the young from the first have fledged, leaving the males to feed the still-dependent fledglings. Early first and second nests and replacements often have larger clutches (4–5 eggs) than later nests (2–3). In a study in California, breeding density of towhees was higher in ungrazed oak–pine* (Quercus–Pinus) *woodlands than in grazed areas. But birds in the ungrazed site, which had more nest-sites, cover and food, experienced lower reproductive success, primarily because of predation during the nestling period.*

[*Pipilo erythrophthalmus erythrophthalmus*, E Pennsylvania, USA. Photo: Dave Maslowski/ Maslowski Productions]

Of 20 ***Blue-black Grassquit*** *chicks genotyped in a study in central Brazil, ten were not related to at least one of the birds providing parental care. There were cases in which paternity was attributed solely to the male attending the nest, some broods having different chicks related to more than one female; nests in which the whole brood or some nestlings were not related to the attending male; and one case in which a chick was unrelated to either "social parent", an apparent instance of intraspecific nest parasitism. This extra-pair fertilization rate of 50% is much higher than the average of 11% found in socially monogamous birds.*

[*Volatinia jacarina jacarina*, Camaçari, Bahia, Brazil. Photo: Pedro Lima]

islands, he observed the variety of small birds present and collected specimens, but, not realizing their significance, he did not keep detailed records of these specimens and did not record where each had been collected. It was only when he returned to London that it struck him that the birds, while closely related, all differed from one another. This realization, and his own scientific reasoning, led Darwin eventually to formulate the principle of natural selection, one of the most significant scientific theories ever to have emerged. Is it possible that, had it not been for Darwin's finches, scientific thinking would have taken an altogether different direction?

Although many emberizids are granivorous, they are usually not considered to be serious agricultural pests. This is because they feed principally on spilled crop seeds and weed seeds, especially seeds of grasses. They are seed predators, and do not disperse seeds. Further, they are not important pollinators.

There are few published data on reproduction of the wild ***Red-crested Cardinal****, but a mixture of anecdotal information and reports on captive birds suggests that they may have up to three broods in a year. The male takes over care of the young when they fledge, and the fledglings remain with the parents until they gain their adult plumage. In captivity, the nestling period is said to be 2–3 weeks. Nestling periods are longer for emberizids (including* Emberiza *buntings) of hotter latitudes.*

[*Paroaria coronata*, Pantanal, Mato Grosso, Brazil. Photo: Haroldo Palo]

*Male and female **Blue Finches** feed their nestlings at a rate of about two visits each per hour. For the first three days after hatching, the female broods the young intensively. She may solicit food from the male by shaking her wings, mimicking the behaviour of the chicks. At first the parents bring small beetle larvae (Coleoptera) and other small insects; as the nestlings grow, they are offered larger insects such as crickets and grasshoppers (Orthoptera). Sometimes an insect may be too big for the chicks to cope with. This picture comes from a sequence in which the chicks fought for, and each attempted to swallow, the item; the male finally ate it himself. The young left this nest when nine days old.*

Status and Conservation

Most of the north-temperate species in this family are at least fairly common, and some are very common. Many breed north of extensive human habitation and in habitats that are of little economic value to people. They are, therefore, in general little affected by human activities other than those associated with mining and mineral exploration, although these can sometimes be on a massive scale. For example, the American Tree Sparrow (*Passerella arborea*) of North America breeds at the limit of trees, in dwarf trees, especially spruce and birch, and most winter in the northern Great Plains in shelterbelts, hedgerows and oldfields. Thus, its breeding habitat is of little commercial value to humans, and human activities perhaps even encourage the development of suitable winter habitat, although this habitat is increasingly being lost to urbanization and other development.

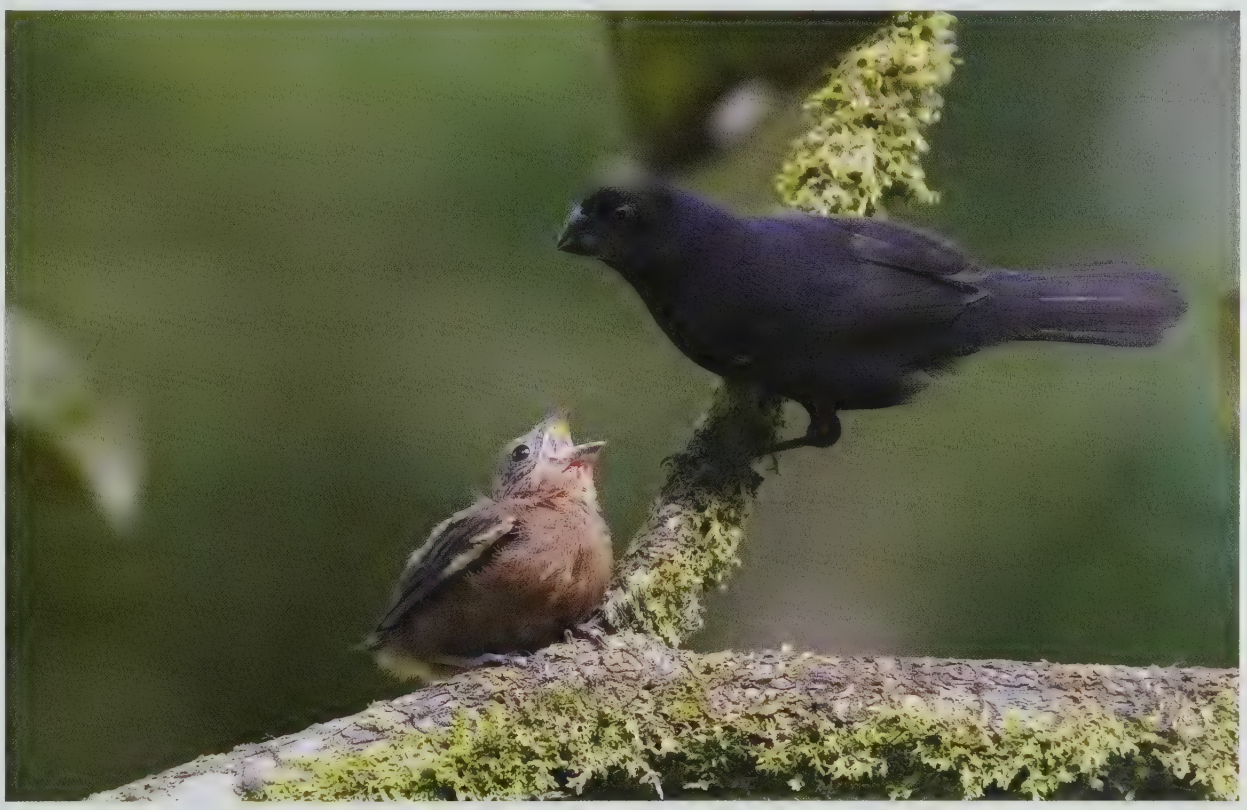
Of the 326 species currently included in the family Emberizidae, 36 are listed as globally threatened. Five of these are Critically Endangered, 14 are Endangered and 17 are Vulnerable. A further 24 species are considered Near-threatened. This means that the future prospects of as many as 60 members of the family, more than 20%, are of some concern.

In America, only three of the many emberizids that occur north of the Isthmus of Tehuantepec, in other words those that are North American in a zoogeographical sense, are believed to be globally threatened. These are Worthen's Sparrow (*Spizella wortheni*) and the Sierra Madre Sparrow, both Endangered, and the Saltmarsh Sparrow, which is Vulnerable.

Worthen's Sparrow is a rare and very local species with an extremely small range and population, both thought to be decreasing. Until recently it was known to breed at just three places in north-east Mexico, namely Las Esperanzas, in Nuevo León, and two sites in Coahuila. In 2006, however, two further breeding localities were discovered in Nuevo León, at La Carbonera and San Rafael, and one in Coahuila, at San José del Alamito, and the species was thought to be breeding also at a additional Nuevo León site, at El Erial–La Casita. This sparrow's global population may number no more than 100–120 mature individuals. The main problem appears to be habitat loss, more particularly the conversion of desert scrub to agriculture or livestock grazing, and there is an urgent need for all of its breeding areas, as well as suitable habitat elsewhere in its range, to be fully protected. The species seems also to have a very low reproductive success, but it is not known what effects this may be having on the population as a whole. In the past, Worthen's Sparrow had a more extensive range, reaching northwards into the south-west USA and southwards in Mexico to at least Puebla, but it was last seen at the southern limit at the end of the nineteenth century. The poorly known subspecies *browni*, confined to west Zacatecas, has not been recorded since 1961 and may well be extinct.

Also in Mexico, the Sierra Madre Sparrow appears to fairly common within its very small range. Even so, it is also apparently declining at a fast rate, and most of the population is confined to one site. A recent survey revealed that the species survives at just two sites. One of these is centred around La Cima and Milpa Alta, near Mexico city, where the population in 1997 was estimated at 5380–6150 adults; the other locality is Ejido Ojo de Agua–El Cazador, in south Durango, where the total population probably does not exceed 50 individuals. Like the previous species, the Sierra Madre Sparrow was once more widespread, being found at four sites in south Durango and extending into north Jalisco and to the Morelos border. Overgrazing by domestic livestock is a major problem, as also are fires, and uncontrolled burning of bunchgrass meadows to create new pasture for sheep and cattle has destroyed large areas of the species' preferred habitat. Much of the tillable habitat in the area of La Cima has been ploughed, and most of the suitable habitat in Durango has been lost to logging and cultivation. At the sparrow's main site, the area of suitable habitat has approximately halved in the decade since the end of the twentieth century. Furthermore, mycotoxins from contaminated grain have caused some mortality, and heavy predation, possibly exacerbated by habitat fragmentation, causes frequent nesting failure. Monitoring of the remaining populations of this species is considered essential, and effective protection of surviving habitat fragments is vital. In addition, local inhabitants should be encouraged to develop appropriate grassland-management strategies and to ensure that contamination by mycotoxins is prevented.

The Saltmarsh Sparrow has been declining because of modification of its coastal marshland habitat. Its range extends in a narrow coastal band over about 20,000 km², from south Maine to



*This male **Rock Bunting** is removing a faecal sac from the nest. For the first few days the parents may eat the faecal sacs, but when the nestlings are older (and their digestive systems more efficient) the parents carry them away before dropping them at a distance. Some emberizids, such as the Golden-breasted Bunting* (Emberiza flaviventris)*, may allow the sacs to accumulate on the nest rim when the chicks are larger. Young Striolated Buntings* (E. striolata) *in India continued to produce faeces in gelatinous sacs until the day before they left the nest, but from fledging onwards their faeces were loose and "freely splashed hither and thither".*

[*Emberiza cia cia*, Navarrete del Río, Teruel, Spain. Photo: Rodrigo Pérez Grijalbo]

south New Jersey, but suitable habitat within this is greatly fragmented, such that the area occupied by the sparrow is less than 2000 km². Although its estimated global population was put at some 250,000 individuals in the early years of the present century, the true figure, based on density estimates, is probably in the range 50,000–100,000 individuals, and probably at the lower end of that range. Continuing loss, degradation and fragmentation of marshlands as a result of urban development is a major concern for this sparrow, as also are invasive species such as *Phragmites* reeds, which render the habitat completely unsuitable for it. On top of this, chemical pollution of marshes is a problem in some places, and a rise in sea levels caused by climatic warming could potentially pose a serious threat.

Disregarding vagrants, altogether 35 emberizid species are found in the Palearctic Region, most of them in the genus *Emberiza*. Several are threatened. The very rare and local Jankowski's Bunting is currently known to breed at just five sites in north-east China, four in Inner Mongolia and one in west Jilin,

*The juvenile **Thick-billed Seed-finch** has pale greyish-brown body plumage and loosely textured feathers. The genders are similar, but some juvenile males have slightly duskier flight-feathers. Complex plumage sequences occur in the Emberizidae, especially in the Neotropics, and the moult patterns of the Thick-billed Seed-finch are different from those of others in its genus. The adult male is all black, but some second-year and third-year males may have a tawny wash on the belly, and even third-year males may retain dusky-washed juvenile feathers.*

[*Oryzoborus funereus salvini*, Limón, Costa Rica. Photo: Boris Nikolov]

and has a maximum known population of about 100 mature individuals. It is listed as Endangered. Its range formerly extended into extreme south-east Russia and extreme north-east Korea, and was more extensive in China, covering wider parts of west Jilin, with breeding also in east Jilin and south Heilongjiang; it was locally common in Heilongjiang in the first half of the twentieth century. In west Jilin, there were 350 breeding pairs in 1994 but none in 2005 at Huichin, and 100 individuals in 2001 but only two in 2008 at Baicheng, where it is now extinct; at Dagang Forest Farm, the population dropped from 60 pairs in 1999 to just ten in 2010. In Inner Mongolia, habitat destruction at Tumiji grassland resulted in numbers falling from about 50 birds to only seven by 2010; of two recently discovered sites in this province, one held 53 individuals, 29 of them males, and the other 13 individuals, of which nine were males, in 2010. The main problem for this rare bunting is that it has very specialized habitat requirements. The dry grasslands that it needs have been widely destroyed by cutting for winter animal fodder, and further losses have been caused by extensive accidental or intentional burning, as well as conversion to agriculture and forestry. Moreover, this species is a ground-nesting bird and its nests are vulnerable to predation and to trampling by domestic animals and humans. Its semi-colonial nesting habits, successful breeding being dependent on the close proximity of other pairs, could be a further restricting factor. Although the Xianghai Nature Reserve gives some protection in China, grassland destruction has occurred even inside reserve areas. This species' future would seem to depend on the creation of a network of surviving grassland patches and much stricter protection from human activities.

Two other Palearctic buntings are listed as Vulnerable. One, the Yellow-breasted Bunting, is fairly common, and even locally abundant, but is declining significantly. Its present global population has been estimated at up to 1,000,000 mature individuals, although the accuracy of that figure seems perhaps doubtful. At the beginning of the twentieth century this bunting spread westwards, colonizing Finland during the period from 1910 to the 1920s, with a further sustained wave of immigration from the 1940s to the 1960s producing a more stable population; numbers began to decline, however, in the 1980s. It was once one of the most numerous breeding passerines across much of Siberia, and is still common in a few regions, but severe declines have been noted in most parts of the breeding range, and local extinctions have occurred since 1990. It has not bred in Finland since the mid-2000s, and its range in Kazakhstan has contracted northwards by 300 km since 1990. A rapid decline has been recorded in the Moscow and Baikal regions of Russia, and severe declines noted in north Japan and Mongolia. Moreover, this species is no longer seen in big numbers at migration watchpoints such as Beidaihe, in north-east China, and populations at wintering sites throughout the range have decreased rapidly over the last 20 years. The main reasons for the marked decline of the Yellow-breasted Bunting are thought to be hunting on the wintering grounds, especially in China, and the conversion of suitable habitat to agricultural use. Its numbers even on pristine breeding grounds have dropped very rapidly, and the foremost cause is probably excessive trapping at migration sites and, especially, wintering sites. Flocks roosting in reedbeds are flushed, caught in mist-nets, cooked and sold as food; previously confined to a small area of south China, this practice has become more widespread, and the hunters now need to travel widely in order to find sufficient birds. Although the practice is now illegal in some areas, it is estimated that more than 1,000,000 individuals are killed and sold annually (see Relationship with Man). Further problems faced by Yellow-breasted Buntings in the non-breeding areas are agricultural intensification, including the shift to irrigated rice production and a consequent loss of winter stubble, which has reduced the amount and quality of the habitat, and the destruction of reedbeds, which has led to the loss of many roosting sites. On the breeding grounds, habitat quality has suffered in some parts of the range; for example, changes in the flow pattern of rivers resulting from dam construction have caused the drying-out of damp meadows, an important breeding habitat. An intensive range-wide survey is required in order to determine the true extent of decline of this species and to assess what conservation measures are required for it.

The other Vulnerable bunting in the Palearctic is the Japanese Yellow Bunting, which breeds in Honshu and migrates to the Philippines. Although there are no reliable population estimates for it, this species is uncommon and appears to have declined. It has become rarer in its traditional breeding areas, and has suffered a significant drop in numbers during the twentieth century. It has been adversely affected by habitat degradation and loss, primarily through agricultural intensification, but more

Snow Buntings *leave the nest at 13 days, but at 16 days of age the fledglings are still relatively immobile, with a very short tail. At 20 days they make short flights in pursuit of their parents and attempt to feed themselves. By the end of the second week after fledging, the wings and tail are similar in length to those of adults. From this point, the chicks spend most of their time in feeding themselves, often in the company of a parent, and the frequency and success of begging behaviour are reduced.*

In South America, the Shiny Cowbird (Molothrus bonariensis) *is a known brood parasite of many emberizids. The* ***Rufous-collared Sparrow*** *is heavily parasitized in Brazil and Argentina. In one sample of 40 nests, 29 contained cowbird eggs. The Shiny Cowbird lays both plain white and spotted eggs, but Rufous-collared Sparrows accept both. The colour of the young cowbird's mouth is, apparently, irrelevant to the sparrow's parental behaviour. Just three of the 29 parasitized nests were successful, but success was low overall: only 13 sparrows fledged from the 40 nests. Four cowbirds fledged from 59 eggs.*

[*Zonotrichia capensis subtorquata*, São Carlos, São Paulo, Brazil. Photo: Haroldo Palo]

especially by trapping for the cagebird trade. In the past, the latter activity was not uncommon in Japan, but nowadays trapping is most serious in southern China, where, as with the preceding species, significant numbers are caught in the passage and wintering areas. The use of pesticides seems also to be a factor in this species' decline; pesticides have caused similar problems in several Asian countries, and are linked with the rapid decline of small passerines in rural areas of south China.

Only one of the nine Afrotropical buntings is at risk. This is the Socotra Bunting (*Emberiza socotrana*), found only on the island of that name lying off the north-east tip of Somalia, in the north-west Indian Ocean. It total population has been estimated at 1400 individuals, representing about 300 pairs, and is thought to be stable. Nevertheless, this bunting may be under threat from increasing grazing pressure and also introduced predators, especially feral cats, black rats (*Rattus rattus*) and small Indian civets (*Viverricula indica*). Because of these factors, coupled with its tiny global range of about 310 km², within which it is patchily distributed at low density, this species is listed as Vulnerable.

Five emberizids are Critically Endangered, three of them restricted to islands. In the South Atlantic archipelago of Tristan da Cunha, the Gough Finch is rare to locally fairly common, with a breeding population estimated at 400–500 pairs, and a total population of some 1050–1350 individuals. It is the only passerine resident on Gough Island, where it was once abundant. Since at least the middle of the twentieth century, however, its numbers have decreased, especially in the lowlands, apparently as a result of nest predation by the introduced house mouse (*Mus domesticus*). Predation by mice has driven this species away from coastal areas and into suboptimal upland habitat, and is causing a very rapid decline in its numbers; the species is now rare at lower elevations in fernbush. The number of territory-holding finches in immature and juvenile plumages has increased, which suggests that, as the population shrinks, many territories become vacant; the proportion of juveniles in the whole population has at the same time decreased considerably, a sign of reproductive failure and an ageing population. Significantly, the finch is still abundant on Penguin Island, a mouse-free offshore stack. Plans are being formulated with the aim of ridding the island of the mice, which are major predators also of seabird chicks on Gough; the early results from a feasibility study appear promising. Gough Island is a nature reserve and a UNESCO World Heritage Site; the human population consists merely of a small number of staff at a meteorological station.

Two of Darwin's finches in the Galapagos Islands, both in the genus *Camarhynchus*, are at serious risk. The Medium Tree-finch (*Camarhynchus pauper*), found in the highlands of Floreana Island, in the south of the archipelago, is uncommon and local. It has a tiny global range of about 23 km², within which its esti-

Most buntings and New World sparrows that breed in the Northern Hemisphere migrate, and at least 22 emberizids in central and southern South America move north during the austral autumn. Nine Sporophila *species are known to be migratory. They include the* ***Black-bellied Seedeater****, which arrives on its breeding grounds in south-east Brazil in October–November and migrates north as far as Goiás and Minas Gerais in February–March. Non-breeding males moult into a female-like plumage. The photo is of two males on the breeding grounds; the bird on the left is not yet showing the black cheeks and flanks of full breeding plumage.*

[*Sporophila melanogaster*, Lava Tudo River, São Joaquim Municipality, Santa Catarina State, Brazil. Photo: Márcio Repenning]

Most of the global population of the restricted-range ***McKay's Bunting*** *breeds on the 309 km² St Matthew Island and 16 km² Hall Island, in the Bering Sea. The total population has been put at 6000 mature individuals, but a recent study estimated the combined populations on Hall and St Matthew at more than 31,000. Although its numbers and range are thought to be increasing, McKay's Bunting is considered Near-threatened. Reindeer* (Rangifer tarandus) *introduced on St Matthew destroyed much of the native vegetation before they died out, and breeding densities are still lower than on Hall.*

[*Plectrophenax hyperboreus*, St Matthew Island, Alaska, USA. Photo: Spectrum Photofile/ AGAMI]

mated population in 2008 was at most 1660 individuals, a reduction of more than 60% since 2004. The greatest numbers are found around the base of the Cerro Pajas volcano, where the species' preferred nesting tree, *Scalesia pedunculata*, is dominant; here, the bird's density fell from 154 birds/km² in 2004 to 60 birds/km² in 2008, and this species is now significantly less common than it was 50–100 years ago. The rapid decrease has been caused by habitat degradation, introduced predators and, especially, the effects of the introduced nest-parasitic botfly, *Philornis downsi*; the adult flies lay their eggs in the nests of the finches, and the maggots feed on the blood of the chicks. This fly seems to be responsible for large-scale decreases in nesting productivity; the situation is not helped by the fact that this tree-finch's only habitat is adjacent to cleared agricultural land with fruiting trees favoured by the adult fly. In addition to this, avian pox infects a significant proportion of individuals. The island has several introduced predators and herbivores, such as pigs, cats, dogs and rats, and suffers extensive habitat destruction and degradation from agriculture and free-ranging domestic livestock; moreover, invasive plant species have led to habitat alteration. The tree *Scalesia pedunculata*, favoured by this species, is now itself endangered on Floreana, surviving only in fragmented patches with a total extent of less than 4 km²; the number of visiting tourists to *Scalesia* habitat have increased more than ten-fold since 2004. Although the Galapagos Archipelago is a World Heritage Site and a national park, the agricultural zone of Floreana, which was this tree-finch's prime habitat, is excluded from protection. Efforts to eradicate the goats and donkeys on Floreana, begun in 2006, have considerably reduced the populations of these grazing mammals. Methods to control or eradicate *Philornis downsi* are currently being tested.

Even more parlous is the situation of the Mangrove Finch (*Camarhynchus heliobates*), which has a global population of 80–120 mature individuals, all within a range of just 1 km² on the north-west coast of Isabela Island. This species used to be present in at least six patches of mangrove on Fernandina Island and on the east, south and west coasts of Isabela. It is probably now extinct on Fernandina, where it was last reported in 1971, and where recent surveys failed to locate it. On Isabela, breeding populations were found in 1997 and 1998 in only two areas, both on the north-west coast, with 37 pairs at Playa Tortuga Negra and 21 pairs at Caleta Black; subsequent surveys reported estimated populations at these sites of, respectively, 36 and 16 pairs in 1999, 24 and 14 pairs in 2007, and, in possibly the most thorough survey, a combined total of about 40 pairs in 2009. Elsewhere on the island, 3–5 territories with probable breeding birds were located in fairly extensive mangroves on the south-east coast. In 2008, several other historical sites on Isabela were searched, as also was Punta Espinoza, on Fernandina, but this finch was found at only one site, Bahia Cártago, on the coast of Isabela, where perhaps four or five pairs were present. Although it is likely that this species has never been common, its range and population have contracted greatly in recent decades, largely because of the introduced black rat, a major cause of nesting failure, having destroyed 70% of the finch's nests in 2007. Other potential threats include feral cats and Smooth-billed Anis (*Crotophaga ani*), both predators. As with the tree-finch on Floreana, a significant additional threat is the muscid fly *Philornis downsi*, found to be present in all nests and at an average infestation rate of 42 per nest. In addition, habitat degradation has probably contributed to the species' decline. Mangroves used by it appear structurally different from those where it is absent, which suggests that it has subtle habitat preferences; it appears to favour mangrove with tall trees, relatively low canopy cover, and plenty of leaf litter and dead wood. The leaf litter is a preferred foraging area of this finch, and, to prevent it from being washed away, it is essential that the mangrove trees are not linked directly to the sea. Because of the Mangrove Finch's very small population, studies of its breeding biology have been undertaken and blood samples analysed, the preliminary results appearing to indicate serious inbreeding. The feasibility of translocating individuals is being assessed, and possible sites for reintroduction on Isabela investigated. A three-year programme involving the taking of ten young annually from the Tortuga Negra colony and releasing them into mangroves on the east coast has begun, and yearly monitoring is continuing. As with the Medium Tree-finch, control of invasive predators and a study of methods to control *Philornis downsi* are underway.

Both of the remaining Critically Endangered emberizids have been described only recently. The Carrizal Seedeater (*Amaurospiza carrizalensis*), discovered on the island of Carrizal, on the River Caroní, in the Venezuelan state of Bolívar, was described as new to science in 2003. It is nowhere common, its global range

Not recognized as a species until the 1990s, the ***Sao Francisco Sparrow*** *has a patchy distribution over a wide area of central Bahia and north Minas Gerais, in Brazil. It has been listed as Near-threatened because its range was thought to be small and its* caatinga *habitat to be suffering rapid degradation and loss. Surveys in 2010, however, gave an estimated extent of occurrence of 56,100 km², and it is now thought that the population is unlikely to be below 10,000 mature individuals. It may warrant downlisting to Least Concern.*

[*Arremon franciscanus*, Chapada Diamantina National Park, Bahia, Brazil. Photo: Andy & Gill Swash/ WorldWildlifeImages.com]

appears to be tiny, and it, not surprisingly, very poorly known. Since the initial describing of this species, it has been found at a further seven sites in the lower Caroní Basin. The entire habitat at the type locality was destroyed by flooding during the building of the Guri Dam, which in addition destroyed other potentially suitable habitat in the vicinity. This seedeater, which must have a very small population, is thought to be declining because of the continuing destruction of habitat. The main threat to the surviving populations is the total clearance of forest. It is possible, or even probable, that the extreme scarcity of records is due in part to the difficulties of surveying the species' habitat. After the habitat at the type locality had been destroyed, three conservation-oriented organizations, together with a hydro-electric company, set up a two-year project to identify and survey potential habitat for this seedeater. The spiny bamboo in which it was first discovered is a most dangerous habitat in which to carry out surveys of any kind, and, because it lies beneath the forest canopy, this habitat cannot be detected by aerial survey. The effective protection of potentially suitable habitat is considered essential for the future survival of the Carrizal Seedeater.

The Antioquia Brush-finch (*Atlapetes blancae*) may already be extinct. It was described in 2008 on the basis of museum specimens from San Pedro, in the central Andes of Antioquia, in Colombia. It is currently known only from museum specimens, three of which exist, all from the type locality, two undated and the third dated 1971. All specimens were collected on a small plateau known as Llano de Ovejas, at 2400–2800 m. Expeditions to San Pedro in 2007 and 2008 failed to find the species. It is thought likely that this brush-finch lived in forest, most of which in this region has already been destroyed for cattle-ranching and commercial flower-growing. Further investigation of its potential distribution is required, followed by intensive targeted searches.

A further emberizid has been listed as Critically Endangered. This is the Hooded Seedeater, known only from the holotype, collected in the 1800s in south-central Brazil. It is considered likely, however, that this was a variant of the Yellow-bellied Seedeater or a hybrid (see Systematics).

In addition to the aforementioned Gough Finch, the three other Tristan da Cunha finches are at risk. The Inaccessible Finch is widespread on Inaccessible Island, with an estimated 10,000 pairs. In the past it was also present on the main island of Tristan, but it vanished within 50 years of the human colonization of the island, probably exterminated by introduced house mice and feral cats. Although this species is abundant within its tiny range, and appears not to be declining, the possible arrival of invasive species could bring about a steep decline in its numbers, perhaps followed shortly by its extinction, as happened on Tristan. Since the establishment of a fisheries patrol vessel, based at Tristan, Inaccessible Island has become more accessible and the risk of accidental introduction of mammalian predators is far greater. In-

Prized for its singing ability, the ***Great-billed Seed-finch*** *has vanished from parts of its former Brazilian range because of trapping for the cagebird trade. Some Brazilian ornithologists report that they have been unable to find it in the wild in recent years. It has a very disjunct range and is found also, very locally, from eastern Venezuela east to French Guiana.* The IUCN Red List, *which includes the race* occidentalis *of the Large-billed Seed-finch* (Oryzoborus crassirostris) *in this species, considers it to be Near-threatened.*

[*Oryzoborus maximiliani maximiliani*, Das Emas National Park, Goiás, Brazil. Photo: Edson Endrigo]

*The **Socotra Bunting** breeds in the highlands of the island of Socotra, in the north Indian Ocean, and may descend to the coast outside the breeding season. Although it has been discovered at several new localities since the late 1990s, its global range is thought to be no more than about 310 km², and even within this tiny area it is patchily distributed and local. The population is thought to be 300–500 pairs. Although apparently not declining, it is at risk from introduced predators because of its small range and probable ground-nesting habits, and is listed as Vulnerable. Well-established invasive mammals such as feral cats, rats* (Rattus) *and civets* (Viverricula indica) *may already be limiting the population.*

[*Emberiza socotrana*, Socotra.
Photo: Peter Ryan]

vasion of the introduced New Zealand flax (*Phormium tenax*) into areas of island cape myrtle (*Phylica arborea*) woodland is a further threat, as it results in habitat degradation. This species is, therefore, considered Vulnerable.

Nightingale Island is the sole home of the two other *Nesospiza* finches. The Nightingale Finch, listed as Vulnerable, has a global range of no more than about 4 km² and an estimated population of some 5000 pairs, of which at least 4000 pairs are on main island and the remainder on two tiny offshore islets. Wilkins's Finch is restricted to an area of probably no more than 2 km² on the main island of Nightingale, where its population is at most 100 pairs. It is Endangered. Both species face the same potential dangers as those threatening the other Tristan da Cunha finches. The risk of accidental introduction of mammalian predators such as rats and mice is of serious concern on all of the islands. For Wilkins's Finch, which seems to be dependent on island cape myrtle, the destruction or degradation of this woodland could be disastrous. Accidental introduction of certain invertebrates or pathogens which could adversely affect these trees, and the fact that a black fungus-like growth, although not yet present on Nightingale, has previously been transported from Tristan to Inaccessible Island is worrying.

Island species, being commonly restricted to a very small range and often adapted to certain conditions, are frequently at risk. In the Caribbean, the St Lucia Black Finch is uncommon to rare within its tiny global range, with a very small population in the range 250–999 mature individuals. It appears to be in slow decline because of continuing habitat loss and degradation, especially the clearing of undergrowth in timber plantations, which makes these areas wholly unsuitable for it. The species' breeding success is compromised by introduced mongooses (Herpestinae) and rats, which prey on both the nest contents and the adults. This finch occurs in two forest reserves and perhaps some other protected areas on St Lucia, efforts are being made to ascertain the species' present distribution and population, and to halt the clearing of undergrowth in wooded areas. This emberizid is regarded as Endangered.

To the south of Costa Rica, the Cocos Finch is the most common landbird on the island of that name. Moreover, it appears able to survive well in disturbed habitats, and habitat degradation may not have any major effects on it. Nevertheless, this species' global range covers no more than some 25 km², and it is therefore vulnerable to chance catastrophic events. Further, introduced rats and cats are potential predators, and grazing by feral deer, pigs and goats could perhaps be an adverse factor, while increasing tourism is a further potential problem. Although the entire island is protected as a national park, and the species is numerous, with an apparently stable population, and is a generalist in habitat preferences, its tiny global range is sufficient for it to be considered Vulnerable.

*Despite a global population estimated at up to one million mature indivduals, and a global range of almost 16 million km², the **Yellow-breasted Bunting** was listed as Vulnerable in 2008. Formerly one of the most numerous breeding passerines in much of Siberia, it has suffered severe declines and has disappeared from parts of its range. Habitat conversion may be a factor, but numbers have plummeted even on pristine breeding grounds. Trapping on the wintering grounds in China is blamed. Each year, more than one million are caught in mist-nets, cooked and sold as "rice-birds".*

[*Emberiza aureola aureola*, Voskresensk, Moscow, Russia.
Photo: Pavel Parkhaev]

*The geographical range of the **Saltmarsh Sparrow** extends in a narrow coastal band over 20,000 km², but suitable habitat is greatly fragmented and it occupies an area of less than 2000 km². Urban development is the major cause of habitat loss. Chemical spills are a threat, and invasive* Phragmites *reeds render saltmarsh habitat completely unsuitable for this species. Saltmarsh Sparrows are found in many coastal protected areas, but sea-level rise owing to climate change could further reduce its habitat, since the extent of urban development means that there is no room for marshes to migrate inland. IUCN raised the Saltmarsh Sparrow's threat status from Near-threatened to Vulnerable in 2004.*

[*Ammodramus caudacutus diversus*, Maryland, USA. Photo: George M. Jett]

Species with limited ranges are always, in a sense, "threatened", even if, at present, they are common in their preferred habitat. The Zapata Sparrow, for example, is confined to Cuba, where it is found as three distinctive populations, which differ in their ecology. The nominate race is isolated in a small area of the Zapata Swamp and numbers more than 250 individuals; its numbers are apparently stable or increasing in response to efforts to preserve suitable habitat. It is threatened, however, by dry-season burning and drainage. The subspecies *sigmani*, restricted to a small section of coastal thorn-scrub, dry forest and cactus stands in south Guantánamo, has a population of perhaps 600–700 individuals, although it was, until recently, thought to have an even smaller range and to number only 110–200 individuals. The habitat of this subspecies is threatened by burning and the subsequent colonization by grasses, followed by fencing for sheep-rearing. The third subspecies, *varonai*, appears to be numerous and very common within its very restricted range on Cayo Coco, in the Camagüey Archipelago, where it occupies dry to semi-wet open forest; unfortunately, Cayo Coco is now being further developed for tourism. This species is believed to be slowly declining, chiefly because of habitat loss and degradation. It is listed as Endangered.

Another emberizid with a very small range is the Yellow-green Finch (*Pselliophorus luteoviridis*), found only in west Panama. This is a poorly known species which has been recorded at few localities. It is probably scarce to locally fairly common, but its estimated population of 10,000–19,999 mature individuals is thought to be decreasing. Its range extends along the Serranía de Tabasará in Chiriquí and Veraguas, and probably also reaches Bocas del Toro and Coclé. The main threat to this species is habitat loss. In east Chiriquí, forest remains only in isolated patches, and the Serranía de Tabasará generally is threatened by clearance for coffee-growing, as well as by grazing, pesticides and fires. The core of the species' distribution, around Cerro Santiago, in the Ngöbe-Buglé indigenous homeland, is undergoing rapid deforestation through subsistence agriculture and cattle-rearing, and the forest clearance is now spreading to the higher elevations which this finch favours. Even within protected areas habitat continues to be destroyed. The Yellow-green Finch is, therefore, Vulnerable.

Likewise Vulnerable, and for much the same reasons, the Tanager Finch (*Oreothraupis arremonops*) has a patchy distribution in the undergrowth of montane forest in the western Andes of Colombia and north-west Ecuador. It is often found in mossy cloudforest at up to 2700 m. It appears to be rare and very local, and has been recorded at only a handful of localities, these generally under land-use pressures. Its population is believed to be decreasing. It is possible that this species' apparent rarity is in part due to the inaccessibility of its habitat, which is wet and has steep, dangerous slopes. Nevertheless, it is certain that much habitat has been lost in recent decades, primarily through human colo-

*The apparent rarity of the **Tanager Finch** may be due in part to the inaccessibility of its habitat, in the undergrowth of steep, wet forest at 1200–2700 m. Patchily distributed in the west Andes of Colombia and north-west Ecuador, this is a restricted-range species of the Chocó Endemic Bird Area. It is known from only a few localities, and these are mostly under pressure from logging, settlement, cattle-ranching, coca cultivation and gold-mining, but a nest with one egg has been found in disturbed forest in Pichincha, in Ecuador. Because of a suspected ongoing decline, it is listed as Vulnerable.*

[*Oreothraupis arremonops*, Jardín, Colombia. Photo: David Fisher]

*The **Black-masked Finch** has suffered extensive loss of its grassland habitats in Peru, Brazil, Bolivia, Paraguay and Argentina, and is likely to be in rapid decline. First said to be "Threatened" in 1988, it has been listed as Vulnerable since 1994. Now rare and local, it seems to be extinct in Chapada dos Guimaraes, in Mato Grosso, but elsewhere in Brazil potentially significant populations occur in some large national parks. A 2009 review found recent records from 14 protected areas in Brazil, four in Argentina, two in Bolivia and one in Paraguay, and the authors suggested that there were grounds for optimism for the prospects of the Black-masked Finch.*

[*Coryphaspiza melanotis melanotis*, 30 km from Santa Ana de Yacuma, Beni, Bolivia. Photo: Daniel Alarcón]

nization following road-building, coupled with extensive logging concessions; in Colombia, the construction of the Cali–Buenaventura and Pasto–Tumaco highways in, respectively, Valle del Cauca and Nariño have had a major impact. The rate of deforestation is increasing, mainly through logging, human settlement, livestock grazing, the cultivation of coca, and gold-mining. Montane forest in the region is not as severely threatened as is that in the lowlands, but some upland habitat has already been destroyed: rarely, areas of cloudforest are illegally burnt, for example, during severe drought, in order to provide grazable land. This species is present in some protected areas, and its population in Munchique National Park, in Colombia, is estimated at 1000 mature individuals.

South America contains a number of emberizid species, in addition to the Tanager Finch, that are globally threatened or rare, most of these having a limited range. They include three Endangered *Atlapetes* brush-finches, besides the Critically Endangered Antioquia Brush-finch, detailed above. The Yellow-headed Brush-

*Like other bamboo-seed specialists, **Temminck's Seedeater** is nomadic, following the irregularly timed seeding events of* Guadua *bamboo. Clearance of forest has reduced the number of such seeding events and increased the distance between them, leading to longer intervals between nesting attempts. The population is thought to be small and rapidly declining, and Temminck's Seedeater is listed as Vulnerable. It is found in a number of national parks, but its unpredictable movements, often involving absences of several years, make it and other bamboo specialists challenging to conserve through the protected-area system.*

[*Sporophila falcirostris*, Intervales State Park, Ribeirao Grande, São Paulo, Brazil. Photo: Edson Endrigo]

The only one of Darwin's finches not found in the Galapagos Islands, the ***Cocos Finch*** *has a very restricted range of no more than 25 km² on Cocos Island, 550 km south of Costa Rica. Present in almost every terrestrial habitat on the island, and highly tolerant of degraded and disturbed habitats, it is common to abundant and the population appears stable. There are no known threats to the island, which is a national park, uninhabited except for the park rangers. But the very small range makes the Cocos Finch susceptible to chance catastrophes, and it is classified as Vulnerable.*

[*Pinaroloxias inornata*, Cocos Island, Costa Rica. Photo: Tui de Roy/ Roving Tortoise Photos]

finch (*Atlapetes flaviceps*) has a very small range in the Colombian Andes, in north Tolima, where its estimated global population is put at 680 mature individuals. For a long time it was known from only three specimens, all from the type locality in the Toche Valley, until, in 1967, it was captured at a site farther south, in La Plata Vieja Valley, in Huila. For many decades little more was known about this brush-finch, but it has now been found to be be locally common at the type locality; unfortunately, there have been no further records from Huila. Continuing habitat degradation is evident within its range, and the species is thought to be in a steady, slow decline. The Black-spectacled Brush-finch (*Atlapetes melanopsis*) was not discovered until 1996, in the Andes of south-central Peru, since when it has been found at only a few localities. It seems to be local and uncommon, and its total population is estimated as lying in the range 2500–9999 mature individuals. The burning of early regenerating natural vegetation in order to maintain and create available pasture is a widespread practice in this species' range, except in steep, rocky

Uplisted from Vulnerable to Endangered only in 2010, ***Jankowski's Bunting*** *is declining so rapidly that by 2011 a status of Critically Endangered already seemed more appropriate. Populations numbered in hundreds in the 1990s are disappearing from their few known breeding places between one season and the next. The species' dry-grassland habitat has been largely destroyed by cutting for animal fodder, burning and conversion to agriculture. Although protected in Russia and North Korea, it no longer occurs in either country. None has been seen at China's Xianghai Nature Reserve since 2003, and numbers at Baicheng fell from 100 in 2001 to two in 2008.*

[*Emberiza jankowskii*, Baicheng, China. Photo: Pete Morris]

*The global range of the Endangered **Sierra Madre Sparrow** has been reduced to two separated sites in central Mexico totalling 42 km², of which it may occupy just 9 km². At one site around La Cima and Milpa Alta, near Mexico city, the population was estimated at 5380–6150 adults in 1997. At the other, recently rediscovered site, in south Durango, at least three breeding pairs occupied an area of 0·5 ha within an 80-ha marsh, with a total population of probably no more than 50. Uncontrolled burning of bunch-grass meadows to create pasture has destroyed much of the species' preferred habitat. Rock extraction at La Cima may open up the last unploughed grassland to cultivation.*

[*Xenospiza baileyi*, La Cima, Distrito Federal, Mexico.

areas and ravines. This constant threat to its remaining habitat suggests that the species' is in continuing decline.

Previously listed as Critically Endangered, the Pale-headed Brush-finch has recently been downgraded to Endangered because its numbers appear to be increasing. It has been found in just one small area in south-west Ecuador, and census data in 2009 suggested a global population of about 220 adults. Within its range, which lies in the upper Jubones Valley, particularly in the vicinity of Girón and Oña, in south Azuay, its habitat of low arid scrubby woodland with patches of grassland has been decreasing for many decades, but concerted conservation action in more recent years has led to an increase in its population. The most significant event was the purchase of the Yunguilla Reserve especially for the protection of this brush-finch. The grazing activity of goats and cattle is a particular problem and seems to diminish the quality of the habitat, while fire and, especially, brood parasitism by the Shiny Cowbird are additional threats. In 2002, some 61% of Pale-headed Brush-finch pairs in Yunguilla Reserve were parasitized, prompting a programme of trapping and removal of the cowbirds; after seven years, the brush-finch population had increased markedly, from fewer than 40 pairs to more than 100 pairs, this aided by habitat restoration. Yunguilla Reserve is vital for this emberizid, holding 98% of known brush-finch territories within its 150–200 ha. There are plans for further land purchases, with the hope that a second reserve can be set up into which, once the present population has risen to 200 pairs, it should be possible to translocate some individuals.

The little-known Grey-winged Inca-finch (*Incaspiza ortizi*), which has a limited range in northern Peru, is listed as Vulnerable. It is known from just four sites, one in extreme north-east Piura, two in Cajamarca and one in La Libertad, and its preferred habitat is dry scrub, especially on hillsides. At the northernmost site, near Huancabamba, the slopes have been extensively cleared for agriculture and pasture, and there appears to be no other suitable habitat in the general vicinity;'if this hilltop were to be burnt, the species would surely be lost from this locality. Farther south, it survives at heavily disturbed sites on steep slopes. Nothing is known of the current size of the population or its trends, but the species seems to tolerate disturbed habitats, and there is no evidence of any decline. Further fieldwork is needed to determine if any undiscovered populations exist elsewhere in the region.

Three of the warbling-finches are globally threatened. Two of these, both confined to Peru, are Endangered. The Plain-tailed Warbling-finch (*Poospiza alticola*) has a fairly small range in the upper Marañón Valley, within which its remaining area of suitable habitat of montane scrub, shrubby areas and low woodland is decreasing and its population is severely fragmented. It is rare to locally uncommon, with an estimated global population in the range 1000–2499 individuals. The cutting of woodland for firewood, combined with the prevention of regeneration because of burning and intensive grazing, reduce the extent of mixed *Polylepis–Gynoxys* woodlands, this species' preferred habitat. Further adverse factors include the shift from camelid-farming to the farming of sheep and cattle, and soil erosion and degradation caused by agricultural intensification, as well as road-building. Moreover, afforestation projects have often been inappropriate, as exotic tree species, instead of native ones, have been planted. Even within the protected area of the Huascarán National Park, in Ancash, where this species is present, habitat degradation continues. Similar problems afflict the Rufous-breasted Warbling-finch (*Poospiza rubecula*), which is also Endangered. This emberizid lives at a few isolated sites at 2500–3800 m on the west slope of the Peruvian Andes, inhabiting bushy undergrowth in mixed dry Andean woodlands dominated by *Oreopanax*, *Myrcianthes* and *Escallonia*, and montane scrub, as well as dry scrub at the edge of *Polylepis* forests. It occurs also in thick scrub on slopes, where it is most closely associated with the composite shrubs *Eupatorium* and *Gynoxys*. Predictably, it is little known and probably very rare, with an estimated 250–999 individuals. Only six individuals have been recorded in Zárate Forest, in Lima, but this is more than at any other locality. Having already suffered extensive habitat loss, this species faces continuing degradation and destruction of its habitat caused by the same activities and actions as those affecting the Plain Warbling-finch, and the rates of loss and degradation have increased in recent years. It is recorded within the Huascarán National Park but even here the habitat is continually being degraded. The effective protection of Zárate Forest is a conservation priority, and surveys to determine the species' precise distribution are required.

The third threatened member of this genus is found in interior southern Brazil. This is the Cinereous Warbling-finch (*Poospiza*

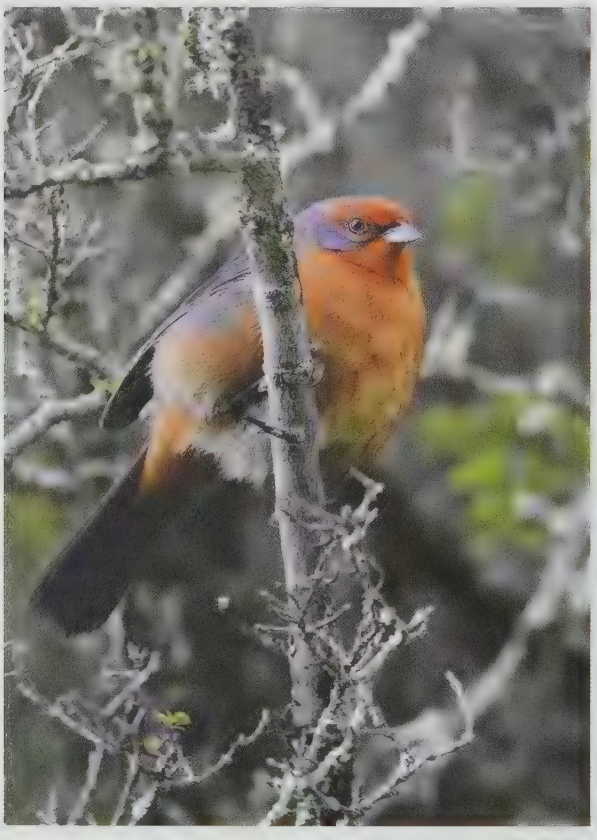
Thanks to intensive conservation efforts, the ***Pale-headed Brush-finch*** *was downlisted from Critically Endangered to Endangered in 2011. Its remaining 27 ha of suitable habitat were purchased in 1999 and securely fenced to remove grazing pressure; brood-parasitic cowbirds* (Molothrus)*, the main threat, were removed. The Endangered* ***Yellow-headed Brush-finch*** *is found only at one site in Colombia, the Toche valley (Tolima); it is still locally common, but declining because of habitat loss.*

[Left: *Atlapetes pallidiceps*, Yunguilla, Ecuador.

Right: *Atlapetes flaviceps*, near Líbano, Colombia. Photos: Jon Hornbuckle]

cinerea), which is uncommon to rare, locally distributed, and listed as Vulnerable. There are recent records of the species from eight sites in Minas Gerais, four in Goiás and one in Distrito Federal; it has not been seen in Mato Grosso since 1904 and in São Paulo since 1901, and is possibly extinct in both regions. Although this emberizid has probably always been rather scarce, the extent of habitat loss that it has suffered suggests that it has probably undergone a significant reduction in its numbers. Since around the middle of the twentieth century, much of the *cerrado* that it needs has been destroyed or severely modified, and government land reform has encouraged the conversion of this unique habitat to eucalypt (*Eucalyptus*) plantations and the growing of exportable crops. Recent reports do, however, suggest that it is able to tolerate, and perhaps even favour, degraded areas, such that it may be more numerous than was previously believed; it seems to be extending its range towards degraded areas in eastern Minas Gerais.

The three races of ***Zapata Sparrow*** *occur in widely separated areas in Cuba, each in a different habitat type, and the three may differ in their ecological requirements. The nominate race has a stable population of more than 250 in the Zapata Swamp, which is affected by drainage and dry-season burning. The race* varonai *is numerous in its very restricted range on Cayo Coco, off the north coast. The race* sigmani*, confined to a small stretch of the south-eastern coast in Guantánamo, may number 600–700. None of the three races is officially protected, but each has been found in a protected area. Suspected of a slow decline due to habitat loss, the Zapata Sparrow is listed as Endangered.*



[*Torreornis inexpectata inexpectata*, Zapata, Cuba. Photo: Zhao Chao]

The genus Nesospiza *is confined to the Tristan da Cunha Group.* ***Wilkins's Finch*** *has a breeding range of no more than 2 km² on Nightingale Island, and a population of at most 100 pairs. It is at risk from the introduction of alien predators and pathogens; invasive plants are already reducing its habitat. Although the population is stable, it is listed as Endangered. Both the Nightingale Finch* (Nesospiza questi) *and, on Inaccessible Island, the Inaccessible Finch* (N. acunhae) *are abundant within their tiny ranges, but are subject to the same threats and are listed as Vulnerable.*

[*Nesospiza wilkinsi*, Nightingale Island, Tristan da Cunha Group. Photo: Peter Ryan]

Both of the mountain-finches in the genus *Compsospiza*, are globally threatened. In Bolivia the Cochabamba Mountain-finch (*Compsospiza garleppi*) was thought to be restricted to Cochabamba, but in 2005 it was discovered in Potosí, where further site records were made in 2008. The species, although locally frequent in Potosí, is thought to be declining at a rate of 10–19% over ten years, and it is considered Endangered. From recent fieldwork, it would appear that this species is tolerant of small-scale habitat alteration and destruction, but it seems to be absent from highly degraded areas devoid of native vegetation. Contrary to earlier reports, it is not a *Polylepis* specialist, but it does require a mosaic of habitats of which *Polylepis* is one. It can do well in agricultural and other sites modified by humans, but only so long as native shrubbery is present. It occurs in Tunari National Park, in Cochabamba, but a large proportion of this has already been converted to exotic pine stands, and the park's future is by no means assured. The replanting of a variety of native shrub species could be the best management strategy for this species. To the south, in the Andes of extreme south Bolivia and north-west Argentina, the Tucuman Mountain-finch (*Compsospiza baeri*) has a fairly small and fragmented range, within which its population is thought to amount to only a few thousand individuals. It is listed as Vulnerable. It was not discovered in Bolivia until 1999, when two individuals were recorded at Estancia Waykhu, in south Tarija. In Argentina, this mountain-finch has been found at comparatively few sites, a total of nine localities in Jujuy, Salta, Tucumán, Catamarca and La Rioja. At all sites it occurs at low densities. As is so often the case, natural habitat in the region has been destroyed by human settlers and their accompanying goats and cattle; the remaining habitat is threatened in some areas by expanding agriculture, and there is the danger that fires in nearby grasslands could spread into ravines occupied by this species. In Tucumán, the El Infiernillo Reserve was created especially for this species, and it has been recorded recently in a couple of other protected sites.

Until 2005, the ***Cochabamba Mountain-finch*** *in Bolivia was thought to be restricted to Cochabamba. A second population was then discovered, in Potosí. It appears tolerant of small-scale habitat alteration and destruction, but seems to be absent from highly degraded areas without native vegetation. Recent visits to most known sites revealed no more than one or two pairs per locality, though more were seen in Tunari National Park, the site of this photo. With no recent information, the population is put at 400–4000, and, because habitat loss is likely to be causing a slow to moderate decline, it is considered Endangered.*

[*Compsospiza garleppi*, Tunari National Park, Cochabamba, Bolivia. Photo: Daniel Alarcón]

Despite its reasonably wide range in central South America, the Black-masked Finch (*Coryphaspiza melanotis*) is everywhere uncommon to rare, very local, and evidently in rapid decline. It requires tall-grass habitat with scattered, low shrubs, and such grasslands are being destroyed at a fast rate by intensive cattle-ranching, mechanized agriculture, afforestation, invasive grasses, excessive use of pesticides and annual burning. In Bolivia, and no doubt elsewhere, the burning of grassland is now a major problem, and is often the result of uncontrolled fires. This finch occurs in a few reserves, but its future is not assured and it is considered Vulnerable. The Endangered Yellow Cardinal, also rare and local, has declined rapidly not only because of extensive habitat loss, but also, and predominantly, because of trapping for the cagebird market. It has a wide range, extending from north and central Argentina eastwards to extreme south-east Brazil and Uruguay, but its global population in 2007 was thought to number only 1500–3000 individuals. It was formerly very common throughout Uruguay, but no more than 300 or so individuals now remain, concentrated in the north-west of the country. Similarly, it used to be widespread and common in Argentina, but has now apparently disappeared entirely from the north-west. In south-east Brazil, where there were always far fewer records, the species may well be extinct. The remaining populations of this striking species are small and fragmented, with the stronghold probably in south-central Argentina. It requires old-growth *Prosopis* forest, or other larger tree species in thorny woodlands, and is absent from areas that are too degraded or young. Some of the habitat loss suffered by this species is due to wood extraction for furniture-making; the replacement of native woodland with exotic eucalypts is not helpful to this and many other species. Large numbers of this finch have been trapped for commercial purposes, not only because of its attractive appearance, but also because it has a musical song. Captive-breeding programmes are being established in Uruguay and Brazil, largely with birds seized from poachers.

The last of the globally threatened members of this family are five *Sporophila* seedeaters, a species-rich genus virtually confined to the Neotropics, although one species occurs as far north as extreme southern Texas, in the USA. Many of these tiny seedeaters are popular as cagebirds, and are consequently often subjected to intensive commercial trapping. This appears to be a major problem in Trinidad, Brazil and Argentina, and has led to the serious decline of several species. The five which are now at risk are the Buffy-fronted, Temminck's, Black-and-tawny (*Sporophila nigrorufa*), Marsh and Chestnut Seedeaters. All are Vulnerable except for the Marsh Seedeater, which is Endangered. The Buffy-fronted Seedeater was formerly locally common in rice fields and at bamboo flowerings in south-east Brazil, with a

*Excessive trapping over many decades is probably the main factor in the rapid decline of the **Yellow Cardinal**, which is highly prized as a cagebird. It was formerly widespread and common throughout much of Argentina and Uruguay, but is now rare except very locally. In Brazil, where it was occasionally recorded as a non-breeding bird, it is probably now extinct. In 2007, the global population was estimated at 1500–3000 birds, and it has for long been considered Endangered. It occurs in a number of protected areas in Argentina, and captive-breeding programmes are being established in Uruguay and Brazil, largely with birds seized from poachers.*

[*Gubernatrix cristata*, Espinilho State Park, Barra do Quaraí, Rio Grande do Sul, Brazil. Photo: Edson Endrigo]

few records from adjacent areas of Paraguay and Argentina, but its numbers have been greatly reduced by deforestation and trapping; it is rare to locally and erratically uncommon. Temminck's Seedeater is a bamboo specialist with a similarly limited range extending from coastal south-east Brazil inland to east Paraguay and north-east Argentina; this rare species has suffered as a consequence of both trapping and habitat destruction, as have other bamboo specialists. The Black-and-tawny Seedeater is known from five areas in extreme eastern Bolivia and adjacent south-west Brazil, where it is at risk as a consequence of habitat destruction; it is rare, and virtually nothing is known about its biology. Marshes and grasslands in extreme south-east Paraguay, north-east Argentina, south-east Brazil and Uruguay are home to the Marsh Seedeater, which is now rare and very local as a result especially of habitat loss and widespread capture for the cagebird trade. It is highly valued as a cagebird because of its unique coloration. Finally, the Chestnut Seedeater, with a range and habitat similar to those of the preceding species, has suffered a rapid decline, and its population is believed now to be small and fragmented; once again, the main causes are large-scale capture for the cagebird trade and degradation and loss of habitat. The two last-mentioned species migrate north after breeding, reaching to as far as south-central Brazil.

Illegal trapping has clearly led to a great reduction in the numbers of these seedeaters in the wild, and alteration or loss of habitat has merely compounded the problem. Indeed, almost all of the *Sporophila* species have suffered from trapping, and this continues today, even though it is banned in many places, including Brazil.

As already noted, some 24 members of Emberizidae are currently listed as Near-threatened. Not surprisingly, most of them have problems with habitat degradation and/or loss. The Cinereous Bunting (*Emberiza cineracea*), for instance, has lost much of its habitat in south-east Europe and west Turkey through development for tourism, and dam construction in south-east Turkey has led to destruction of habitats not only because of flooding of the land, but also through resettlement of displaced villagers and their livestock to hitherto thinly populated areas. The Ochre-rumped Bunting (*Emberiza yessoensis*) breeds from extreme eastern Mongolia east to extreme south-eastern Russia and Japan, and is scarce and declining throughout its range. All indications are that this decrease is related to continuing loss of wetlands across its breeding range and destruction of coastal marshes on the wintering grounds, mainly in east China. In addition, the recently discovered breeding area in Mongolia is threatened by overgrazing and drought.

Some of the Near-threatened species are potentially at risk because of habitat loss combined with trapping. One such example is the Coal-crested Finch (*Charitospiza eucosma*), uncommon and local in east-central Brazil; its moderately small global

*Drainage or overgrazing of its wet grassland breeding habitat is probably the main cause of the decline of the **Marsh Seedeater**. Heavy trapping for the cagebird trade has also extirpated this species in parts of Argentina and threatens populations in the Río Uruguay basin. It is protected in both countries, but the law is not effectively enforced. With 1000–2499 birds surviving at fewer than ten known sites, it is listed as Endangered. It breeds at Potrerillo de Santa Teresa Reserve, in Uruguay, and Iberá Provincial Reserve, in Argentina. Emas National Park, in Brazil, is possibly an important wintering site, and the species is studied in San Rafael National Park, in Paraguay.*

[*Sporophila palustris*, Espinilho State Park, Barra do Quaraí, Rio Grande do Sul, Brazil. Photo: Márcio Repenning]

population is likely to be declining owing to habitat loss caused by conversion of *cerrado* to agriculture, as well as effects of trapping for cagebird trade. Others have a limited range, as does, for example, the Slender-billed Finch (*Xenospingus concolor*), which is confined to a few scattered river valleys and coastal lagoons in the Pacific lowlands from central Peru south to northern Chile, although it is fairly common at least in the southern part of its distribution.

Importantly, some species are not "officially" at risk or potentially so, but may give cause for concern, sometimes at a local level. Some of the seedeaters have suffered substantial losses because of the cagebird trade. This seems to be the case with the Grey Seedeater and Chestnut-bellied Seed-finch (*Oryzoborus angolensis*) in Trinidad, where the latter, in particular, is highly prized as a cagebird because of its song. Both species are often trapped in Trinidad, and are now rare there as a consequence.

In north-west Europe, and especially in Britain, many buntings have declined greatly in recent decades. Indeed, the Cirl Bunting almost became extinct in Britain in the 1980s, at the end of which decade there were just a little more than 100 pairs left, all in a small area of south Devon, in south-west England. At the turn of the previous century, this had been a very common species right across the southern third of England, where it was a familiar sight in villages and around the edges of towns. The near-demise of this bunting had been caused, it seems, by changes in agricultural practices which led to a lack of available food in the form of grain and weed seeds, the species' staple winter diet. After two decades of attempted persuasion, conservationists finally managed to convince farmers and other landowners that it was possible, by leaving a small area of their land "wild", to redress the balance and provide sufficient weed seeds for the buntings to survive. Moreover, by planting spring barley and leaving the stubble over the winter, the farmers were able to ensure that the birds had a plentiful supply of food through the winter months. This strategy worked, and by 2011 the Cirl Bunting population had recovered to almost 1000 pairs and was beginning to expand into nearby areas.

Similarly, the Corn Bunting has suffered a major drop in numbers in Britain, apparently for similar reasons to those which first depressed the Cirl Bunting's population, and the Yellowhammer, too, has exhibited signs of a significant decrease in recent years. It appears fairly indisputable that changes in agricultural practice are the problem, as removal of the buntings' food source was the chief cause of winter mortality. This can be compensated for, however, by the provision of grain, large-seeded grasses and other broad-leaved weeds, particularly in late winter and early spring, which has been found to improve the adult survival rates considerably.

Due to their intrinsically limited ranges, all species and populations confined to one or a few small islands are potentially at risk. The "Ipswich Sparrow", race *princeps* of the widespread and common Savannah Sparrow, breeds only on Sable Island, in Nova Scotia, and winters along the Atlantic coast of North America, primarily in the USA from Maine south to Cape Hatteras, in North Carolina, almost exclusively in marram grass on coastal dunes. Although the Ipswich Sparrow is common on Sable Island, fewer than 2000 individuals breed there. The population has remained stable in recent time, but the island itself is a low sand spit in the North Atlantic, and rising water levels or a bad storm could destroy it. Further, parts of the sparrows' wintering habitat are being developed for cottages, and, although the area is generally north of the hurricane zone, a major storm could do severe damage. The Ipswich Sparrow is a well-marked and distinct population and might ultimately be recognized as a separate species. The San Benito Sparrow, a close relative of the Savannah Sparrow, is resident on Islas San Benito, three small islands off the west coast of Baja California, in north-west Mexico. It is abundant but mice, possibly deer mice (*Peromyscus*), have been introduced to one of the islands, and an effort is being made to eradicate the mice by poisoning them, after which it is planned to boost the sparrow populations. Both of these island taxa are vulnerable because of their severely limited ranges.

The Guadalupe population of the Dark-eyed Junco, subspecies *insularis*, sometimes recognized as a distinct species, is confined to that island, about 280 km west of Baja California, and was once common there. It appears to be catholic in its habitat requirements, being found in Guadalupe cypress (*Cupressus guadalupensis*), Monterey pine (*Pinus radiata*) and island oak

*The **Gough Finch** is the only passerine resident on Gough Island, the most southerly of the Tristan da Cunha Group. Its numbers have decreased since at least the mid-20th century, apparently a result of nest predation and competition for food by the introduced house mouse* (Mus musculus). *The density of territorial pairs roughly halved between 1990 and 2007, and the number of territory-holders in immature and juvenile plumages has increased. At the same time, the proportion of juveniles has decreased greatly, indicating reproductive failure, and the species is listed as Critically Endangered. Survivors have been driven into suboptimal upland habitat, though the finch is still abundant on Penguin Island, a mouse-free offshore stack.*

[*Rowettia goughensis*, Gough Island, Tristan da Cunha Group. Photo: Tui de Roy/ Roving Tortoise Photos]

Two Galapagos finches are Critically Endangered. The ***Mangrove Finch*** *is now thought extinct on Fernandina, and 80–120 birds, in perhaps two viable populations, remain on Isabela. Predation by introduced black rats* (Rattus rattus) *is the main problem. The main threat to the* ***Medium Tree-finch*** *is the nest-parasitic fly* Philornis downsi*; in 2004–2008, only 4–8 % of nests produced fledglings. Methods to control the fly are being tested.*

Right: *Camarhynchus pauper*, Cerro Paja, Floreana, Galapagos. Photo: Tui de Roy/ Roving Tortoise Photos]

(*Quercus tomentella*), and it is now found in stands of tree tobacco (*Nicotiana glauca*) on the beach. The junco's numbers have been depressed as a consequence of predation by feral cats and overgrazing by goats. Apparently, most of the cats have died of starvation, and 20,000 goats were removed in 1990. In the late 1980s, it was estimated that there were perhaps 100 juncos on the island.

In summary, habitat destruction, both by humans and through natural causes, has probably little affected numbers of north-temperate or African emberizids, but it has had a significant negative effect on many South American taxa, which tend to have smaller ranges. In South America, the trapping of wild birds for the cagebird trade has had an adverse impact on many species, especially the seedeaters and the Yellow Cardinal. Equally, the trapping of buntings for trade and for food has been carried out on a massive scale in eastern Asia, resulting in the serious depletion of some species' populations.

On the positive side, however, there are many conservation programmes in place in various parts of the world, and it has been amply demonstrated that these can help threatened species to recover. With the future prospect of climate warming and the many and varied changes which this could bring to habitats everywhere, there is a greater need now than perhaps ever before for conservationists, wildlife enthusiasts, government bodies, landowners and all interested parties to work together to ensure that the Emberizidae, no less than other taxa, continue to thrive on the planet. These are delightful species, and they will surely continue to delight and intrigue humans for a long time to come.

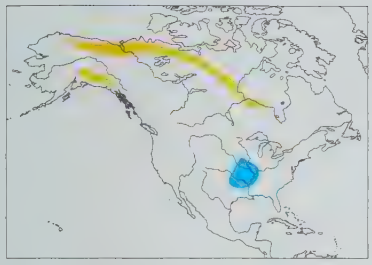
PLATE 39

inches 3
cm 8

Genus *CALCARIUS* Bechstein, 1802

1. **Smith's Longspur**



Calcarius pictus

French: Plectrophane de Smith **German**: Goldbauch-Spornammer **Spanish**: Escribano de Smith

Taxonomy. *Emberiza* (*Plectrophanes*) *picta* Swainson, 1832, Carlton House, on banks of the Saskatchewan River, Saskatchewan, Canada.
Molecular studies indicate that genus is basal to both the New World and the Old World emberizids, and closely related to *Plectrophenax*; has been suggested that these two genera and *Rhynchophanes* be placed in a separate family, Calcariidae. Monotypic.

Distribution. Breeds NE & EC Alaska and NC Canada from extreme N British Columbia E across N Yukon and N & EC Mackenzie to S Nunavut, NE Manitoba and extreme N Ontario. Winters in S USA from SC Kansas, Oklahoma and N Texas E to Arkansas (especially NW), W Tennessee, Mississippi and N Alabama (rare).

Descriptive notes. 14–17 cm; 21–32 g. A fairly large bunting, with white in tail, relatively large head and short tail; sexes differ in coloration. Male breeding has forehead and crown dark brown or black, often flecked with white towards back of crown; supercilium, lores and supraloral spot white; white patch on ear-coverts, boldly outlined by wide black postocular area and moustachial stripe, and boldly edged black towards neck; white submoustachial stripe; nape bright buffy; upperparts black, feathers edged bright buff (appears streaked); upperwing brown, lesser upperwing-coverts mainly white, outer ones mostly black, median and greater coverts narrowly edged buffy-

white at tips, often only narrowly on greater coverts (forming one or two indistinct wingbars); tail dark, lateral two pairs of rectrices mostly white; throat and underparts uniformly warm ochraceous buff; iris brown; bill dusky, brownish-yellow base of lower mandible; legs brown. Male non-breeding has similar pattern, but black on head replaced by streaky brown, throat whitish and median and greater upperwing-coverts more distinctly tipped white; breeding plumage obtained through wear. Female is patterned like non-breeding male, but crown dark brown, flecked with buff, supercilium, lores and ear-coverts light buffy brown, boldly edged with dark brown, upperparts dark brown with buffy feather edges. Juvenile is like non-breeding adult, but perhaps more heavily streaked on throat and breast; apparently completes post-juvenile moult on breeding grounds. VOICE. Song "tat a tee twe twe twee-werr-tee we chew", with ending syllables emphasized, somewhat like song of Chestnut-sided Warbler (*Dendroica pensylvanica*). Call a staccato rattle, "tic-tic-tic-tic"; also gives sneezy "tseu" call.

Habitat. Breeds in moist tundra at edge of tree-line, where found in sedges (*Carex*) and grasses interspersed with heather and small trees, chiefly Lapland rhododendron (*Rhododendron lapponicum*), tamarack (*Larix laricina*) and spruce (*Picea*). On migration and in winter may be found in fallow fields, but more common in short-grass prairie, often with three-awn grass (*Aristida*); typically likes areas with ankle-high grass or alfalfa (*Medicago*). Sea-level to 1200 m.

Food and Feeding. In summer feeds young with grasshoppers (Orthoptera), emergent dragonflies (Odonata), adult dipteran flies (of families Tipulidae, Chironomidae, Calicidae) and Lepidoptera. In winter feeds mainly on seeds, especially of *Aristida*. Forages principally on or near ground or low in vegetation. In non-breeding season in flocks, which can be rather secretive and difficult to see in grass habitat; compared with other longspurs, this species prefers the tallest grass and tends to be the most difficult one to spot, in this respect being reminiscent of a pipit (*Anthus*).

Breeding. Start of egg-laying varies depending on local weather conditions, e.g. at Churchill, in Manitoba, first eggs from as early as 9th Jun to as late as 21st Jun; in most seasons clutch initiation tends to occur after second week of Jun; double-brooding rare. Polygynandrous; no pair-bond formed, but female mates with 1–3 males, and males, in turn, mate with several females. Nest built by female, taking 3–4 days, a woven cup of dry grasses and sedges, lined with hair, lichen or wool, but most often with ptarmigan (*Lagopus*) feathers, placed on ground in depression in relatively dry hummock, near rhododendrons or dwarf birches (*Betula glandulosa*), or among sedges. Clutch 4–6 eggs (usually 4), pale green or greyish with darker purplish spots, dark lines or splotches; incubation entirely by the female, period 11–13 days; chicks fed by both sexes, nestling period 7–9 days; young usually cannot fly until at least 12 days old, in early stages they run quickly through the grass.

Movements. Migratory. Males arrive on breeding grounds before females, and apparently also migrate S earlier. Migrates in flocks which are usually monospecific, but occasionally found with *C. lapponicus* and *Plectrophenax nivalis*. Compared with *C. lapponicus*, present species migrates earlier in autumn and later in spring, arriving 1–2 weeks later than former in areas of breeding sympatry. Migration begins late Mar, most moving N in Great Plains and Midwest into early May, and arrives in Canadian Prairie Provinces by mid-May; arrival on breeding grounds such as Churchill (Manitoba) in late May, but peak in early Jun, with some weather-related variation (e.g. in very cold spring of 2000 arrival at this site not until middle to late Jun). Autumn departure mainly from Aug to mid-Sept, reaching wintering grounds in Oct to early Dec; leaves Yukon late Jul to Aug, rarely remaining to early Sept, and departs from Churchill mid-Aug to early Sept; passage through Canadian Prairies during late Aug to mid-Sept; in USA migrates through Great Plains and Midwest (E to W Indiana). In winter commonest in SC Kansas and NC & NE Oklahoma. A rare migrant in W Great Lakes region; casual vagrant as far as both coasts, primarily in autumn and winter.

Status and Conservation. Not globally threatened. Classified as "Rare" in the USA (Yellow WatchList priority species for conservation). Generally uncommon, but locally common in appropriate habitat. Estimated global population fewer than 75,000 individuals. This species' breeding habitat has been little affected by human activities. Possible future impact of climate change not yet assessed.

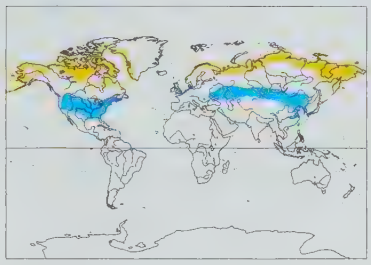
Bibliography. Alderfer (2006), Anon. (1998), Beadle & Rising (2002), Briskie (1992, 1993a, 1993b, 1999, 2009), Briskie *et al.* (1998), Cooke (1911), Dunn & Dunn (1999), Hellmayr (1938), Howell & Webb (1995), Irving (1960), Jehl (1968, 2004), Jehl & Hussell (1966), Kemsies (1968), Kemsies & Randle (1964), Kessel & Gibson (1978), Klicka *et al.* (2000), Lebbin *et al.* (2010), Littlefield & Pakulak (1969), Martin *et al.* (1981), Ormston (2000), Peck & James (1987), Pyle (1997), Ridgway (1901), Rising & Beadle (1996), Sage (1976), Sinclair *et al.* (2003).

2. Lapland Longspur

Calcarius lapponicus

French: Plectrophane lapon **German**: Spornammer **Spanish**: Escribano Lapón
Other common names: Lapland Bunting

Taxonomy. *Fringilla lapponica* Linnaeus, 1758, Lapland.



Molecular studies indicate that genus is basal to both the New World and the Old World emberizids, and closely related to *Plectrophenax*; has been suggested that these two genera and *Rhynchophanes* be placed in a separate family, Calcariidae. Geographical variation appears to be mainly clinal; proposed race *subcalcaratus* (described from Greenland) is treated as a synonym of nominate and *kamtschaticus* (E Kamchatka) as a synonym of *coloratus*. Three subspecies recognized.

Subspecies and Distribution.

C. l. alascensis Ridgway, 1898 – breeds Pribilof Is, N & W Alaska (including St Lawrence I, Nunivak I, Aleutian Is, Kodiak I and Middleton I) and NW Canada (N Yukon and NW Northwest Territories); winters in extreme S Canada (S British Columbia) and USA (W Montana and S South Dakota S to NE California, N Arizona and N Texas, casually S to C California and E to Ohio).

C. l. lapponicus (Linnaeus, 1758) – breeds N Canada (S to C Nunavut, N Ontario, N Quebec and N Labrador) and W & S Greenland, and from W & N Fennoscandia E across N Siberia (including S third of Novaya Zemlya, New Siberian Is and Wrangel I) to Bering Strait; winters in USA (Colorado E to Wisconsin, S to N Texas, Tennessee and Delaware, casually Louisiana and Florida) and SE Canada (S Ontario, Vermont and C Nova Scotia), and in Palearctic on S North Sea shores, CE Europe and E across C Asia to Russian Altai, Mongolia and N China.

C. l. coloratus Ridgway, 1898 – breeds E Siberia around N portion of Shelekhova Gulf, on Kamchatka Peninsula and Commander Is; winters in E China S to R Yangtze (and occasionally Sakhalin I, Korea and Japan).

Descriptive notes. 15·5–17 cm; 22·5–35 g. A fairly large and stocky emberizid with relatively short tail, deep-based, short and triangular bill, long wing (long primary extension), and white edges of tail. Male nominate race breeding (plumage acquired through feather wear) has black crown and side of head to throat and upper breast; pale buffish to white supercilium from above eye (often faintly in front of eye) to rear of ear-coverts, where it meets white band that extends diagonally across side of head to side of breast; nape rufous, upperparts blackish-brown, streaked sandy buff, rump a little paler and greyer; upperwing-coverts blackish, lesser coverts with pale sandy edges, medians with buff-white edges, greaters with broad chestnut edges and whitish tips, flight-feathers dark brown, secondaries broadly edged rufous-buff, outer webs of tertials with broad chestnut edge; tail dark brown, outer two feather pairs with white at edge and tip; underparts from side of upper breast pale buffish to white, black band from breast extending as broad streaks down flank; iris brown; bill pale yellow to orange, small black tip; legs brown to black. Male non-breeding has dark crown with sandy median crownstripe, rufous on nape veiled with buff, distinctive face pattern of warm buff outlined by black along edge of ear-coverts; entire upperparts streaked, appearing much more brown and rusty than in breeding plumage, upperwing more extensively rufous, with obvious rufous panel on greater coverts, these and median coverts more distinctly tipped white to buffish (in contrast to rufous of rest of greaters), tertials brightly edged rufous and tipped whitish; throat whitish, upper breast with variable blackish (often forming breastband), rest of underparts white, some brownish streaking on flanks; bill dull brownish. Female breeding is like non-breeding male, but plumage more worn, thus head paler and with blacker lateral crownstripe, eyestripe, moustachial stripe and malar, nape often more rufous, often has whitish rear supercilium and whitish area behind ear-coverts, generally less black on breast. Female non-breeding resembles non-breeding male, but generally duller and somewhat paler, nape browner or greyer (not rufous), little or no black on breast; bill dull pinkish-brown. Juvenile is similar to non-breeding adult, but darker, duller and more streaky-looking, having nape dark-streaked buffish with no rufous, breast and flanks yellowish-green to buffish with prominent dark streaking, contrasting white belly. Race *alascensis* is paler than nominate, streaking above narrower, black on flanks reduced, supercilium more ochre-tinged, bill larger; *coloratus* is larger than others, much darker above, with edges of greater coverts and tertials bright rusty. VOICE. Song, usually in flight, also from ground, a pleasant warble, e.g. "vree didi vreer di vridi viidiu". Distinctive "tew" call and a dry rattle both given in flight; in this respect resembles *Plectrophenax nivalis* (congeners do not give "tew" calls interspersed with rattles).

Habitat. Breeds in tundra at edge of tree-line, where found in sedges (*Carex*) and grasses (Poaceae) interspersed with heather and small trees such as Lapland rhododendron (*Rhododendron lapponicum*), tamarack (*Larix laricina*), spruce (*Picea*) and willow (*Salix*); avoids thickets and forest, and, unlike *Plectrophenax*, generally not found in rocky habitats. In Greenland, more often found inland than on coast; prefers wet swampy land in a low carpet of heath, with crowberry (*Empetrum*) and dwarf birch (*Betula glandulosa*). On migration and in winter found in open areas and farmland, including fallow fields, dunes and coastal grassland, also in short-grass prairie, steppe and desert-steppe, and at golf courses and airports. From sea-level to 500 m; in E Asia, higher in winter, e.g. up to 1500 m in Mongolia; in Norway, breeds up to 1300 m.

Food and Feeding. In breeding season, mainly invertebrates (especially Diptera), especially craneflies (Tipulidae) in Alaska. Opportunistically feeds on larvae of blowflies (Calliphoridae) on carcasses; also takes larval Lepidoptera, Hymenoptera and beetles (Coleoptera), as well as spiders (Araneae) and earthworms (Lumbricidae). On Devon I, in N Canada, 92·7% of items fed to nestlings and fledglings were adult insects. In winter feeds mainly on seeds, including those of *Aristida*, oats (*Avena*), *Poa*, foxtail (*Chaetochloa*), millet (*Setaria*) and wheat, also dock (*Rumex*), *Polygonum*, chickweed (*Stellaria*), shepherd's-purse (*Capsella*), plantain (*Plantago*) sedges (Cyperaceae), and rushes (Juncaceae). Contents of 600 stomachs from USA (Kansas) in Jan–Feb included 96% vegetable matter and 4% animal. Forages principally on or near ground or low in vegetation; has peculiar habit of foraging with legs crouched, often giving impression that belly is touching ground, with legs hidden below. Runs or walks from tussock to tussock. Often picks small arthropods from ground or from flowers (commonly *Rubus*, *Dryas*). Singly or in small groups during breeding season. In non-breeding season often in larger flocks, sometimes of hundreds and very occasionally thousands of individuals; mixes freely with other buntings, finches (Fringillidae) and larks, especially Horned Lark (*Eremophila alpestris*) and also Eurasian Skylark (*Alauda arvensis*).

Breeding. Median dates for start of egg-laying range from 30th May to 27th Jun, depending on locality (and at any given site clutch initiation tends to be closely synchronized within population); first-egg dates generally later at higher latitudes, but throughout Alaska and the Yukon laying c. 13 days earlier than in rest of Canadian Arctic; double broods rare, and probably not successful. Monogamous. Male arrives on breeding grounds c. 3–6 days before females, and advertises territory by performing parachuting song flight as he drops with outstretched wings. Nest built by female, a cup of dry grass, leaves and moss, lined with hair and feathers, in particular ptarmigan (*Lagopus*) feathers, placed on ground, usually near clump of vegetation (e.g. *Rhododendron lapponicum*), occasionally under tipped rock, and generally concealed in vegetation. Clutch is 1–8 eggs (usually 4–6), variable in colour from pale greenish, bluish or greyish, with varying amounts of rusty or brownish spotting and scrawls; incubation by female alone, period 10·5–13 days; chicks fed by both parents feed the young about equally, nestling period 8–11 days; young initially unable to fly, run in grass, flying abilities stronger at 13–15 days.

Movements. Migratory, moving both diurnally and nocturnally. Spring migration from early Feb to early Mar in North America, with arrival on breeding grounds in late May and early Jun. Leaves wintering range late Feb to early Mar, moving through N states and S Canada during late Mar to early May. Alaskan breeders move N along apparently three different routes during first half May (Pacific coast of British Columbia and Alaska; mountain valleys in British Columbia and S Yukon; and from prairies of Alberta and E British Columbia to upper R Yukon drainage), peak flights in Brooks Range lasting for c. 10 days starting 11th–20th May; in Manitoba (Churchill) arrives in

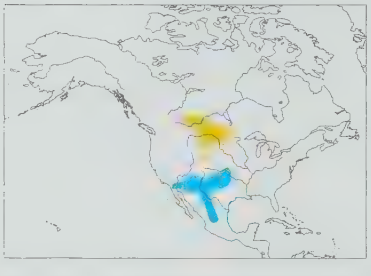
On following pages: 3. Chestnut-collared Longspur (*Calcarius ornatus*); 4. McCown's Longspur (*Rhynchophanes mccownii*); 5. Snow Bunting (*Plectrophenax nivalis*); 6. McKay's Bunting (*Plectrophenax hyperboreus*).

mid-May, peak during late May and early Jun, in warmer years most have passed by 7th Jun, but in cold years many remain into late Jun. Arrival on breeding grounds in Alaska varies, in SW and Aleutian Is from as early as late Apr to early May, but farther N on W coast arrives during first two weeks of May, while in extreme N (in Barrow and the North Slope) arrives late May; similarly, in arctic Canada reaches S extreme of range by mid-May and N limit by mid-Jun. Autumn migration starts late Aug to early Sept in Alaska, some remaining into Oct, and birds arrive on US wintering grounds in Kansas and Arkansas in early Nov; on islands of Nunavut departure begins mid-Aug, most are gone by late Sept, and small minority may remain until mid-Oct; farther S, migrants occur on N shore of L Superior between middle of Sept and late Oct, with peak in early Oct, and in S Ontario passage peaks between late Oct and mid-Nov, some still moving S into early Dec; in N California peak movements are from first two weeks of Oct into Nov. Migrates singly or in small flocks; often associates at stopover sites with Horned Larks, and occasionally with other longspurs and *Plectrophenax nivalis*. In Greenland, departure largely from mid-Aug to mid-Sept, minority remaining until early Nov. In Palearctic, arrival of autumn migrants in Britain and other parts of W Europe as early as Sept. Spring migration occurs in Feb through May, with most passage in N Germany and Denmark in mid-Apr; arrival in Greenland in May and early Jun. At foot of Mongolian Altai: spring migration mid-Mar to May (exceptionally to early Jun); autumn migration late Sept to late Dec. Ringing recoveries suggest that most Greenland breeders winter in North America, although some may head to Europe for non-breeding season. Strong evidence for facultative migration during winter, in particular during strong snowfalls, when this species may move farther S, including during night.

Status and Conservation. Not globally threatened. Abundant or very common in appropriate habitat. Has extremely large circumpolar range, within which total population estimated as being as high as 150,000,000 mature individuals. Recently bred for first time in Iceland. In North America, breeding density apparently has decreased in S parts of range, but this probably reflects climatic change. Breeding habitat has been little affected by human activities. In winter feeds in agricultural lands, and occasionally many have been killed with pesticides designed to combat insect pests. Large numbers have been killed by flying into fixed objects during migration. Unusual mortality includes an estimated 1,500,000 individuals killed during a snowstorm in SW Minnesota and NW Iowa on 13–14 Mar 1904.

Bibliography. Anon. (1998), Beadle & Rising (2002), Bennike & Dyck (1986), Boal & Andersen (2005), Brewer *et al.* (2000), Busche & Dierschke (2004), Castell & Castell (2009), Cramp & Perrins (1994), Fox, Francis, Madsen & Stroud (1987), Fox, Francis, McCarthy & McKay (1992), Francis *et al.* (1991), Gabrielson & Lincoln (1959), Gierow & Gierow (1991), Glutz von Blotzheim & Bauer (1997), Hellmayr (1938), Howell & Webb (1995), Hussell (1972), Hussell & Montgomerie (2002), Irving (1961), Jehl & Smith (1970), Kenyon (1961), Klicka *et al.* (2000), Liang Gang *et al.* (2008), Madsen (1982), McLaughlin & Montgomerie (1985), McNair *et al.* (2008), Peck & James (1987), Pyle (1997), Ridgway (1901), Rising & Beadle (1996), Roberts (1907), Salomonsen (1950), Sedinger (1986), Sutton & Parmelee (1955), West *et al.* (1968), Williamson (1968), Williamson & Emison (1971).

3. Chestnut-collared Longspur



Calcarius ornatus

French: Plectrophane à ventre noir **Spanish**: Escribano Collarejo
German: Gelbkehl-Spornammer
Other common names: Chestnut-colored Longspur

Taxonomy. *Plectrophanes ornata* J. K. Townsend, 1837, prairies of Platte River = near forks of Platte River, western Nebraska, USA.

Molecular studies indicate that genus is basal to both the New World and the Old World emberizids, and closely related to *Plectrophenax*; has been suggested that these two genera and *Rhynchophanes* be placed in a separate family, Calcariidae. Present species has hybridized with *Rhynchophanes mccownii*. Monotypic.

Distribution. Breeds in S Canada (from S Alberta, S Saskatchewan and SC Manitoba) S in Great Plains to NE Colorado, W Nebraska, N (locally also E & SC) South Dakota and W Minnesota; winters from S USA (S California and Arizona E to N Colorado, C Kansas, C Oklahoma and N Louisiana) to NC Mexico (Sonora and W Coahuila S to Zacatecas and Aguascalientes).

Descriptive notes. 13·5–16·5 cm; 17–23 g. The smallest longspur, medium-sized and with much white in tail. Male breeding has black crown with white spot in middle; long white supercilium, black eyestripe behind eye joining with black line on rear ear-coverts; lores, side of face and throat pale yellow-ochre; nape bright chestnut; upperparts brown, feathers broadly to narrowly edged pale buff; upperwing brown, greater coverts and tertials broadly edged buff, lesser upperwing-coverts mainly black, innermost ones of lowest row white; tail with outer two feather pairs mostly white, adjacent pairs white with blackish tip, amount of black increasing towards central pair, which is wholly black (in flight, looks white with dark central triangle); chin and throat pale creamy; breast, belly and flanks black (rarely, admixed chestnut), lower belly and undertail-coverts whitish; iris brown; bill dark brown to black along culmen and also underside of lower mandible, otherwise pale bluish-grey; legs dull pink to brown. Male non-breeding is like breeding male, but black areas on head and underside and chestnut on neck obscured by brownish or dull buffy feather tips; breeding plumage acquired through wear. Female breeding has crown beige, thinly streaked with brown, supercilium and lores pale buff, side of face brown; nape brown, may be tinged with chestnut; upperparts brown, thinly streaked darker brown; tail pattern as on males, but paler and browner; upperwing brown, greater upperwing-coverts and tertials broadly edged with buff, lesser coverts mainly dark greyish-brown, innermost ones of lowest row white; throat, breast, flanks and belly buffy to buffy grey, thinly streaked with brown, usually with varying amounts of dark brown or blackish feathers; undertail-coverts buffy; bill similar to that of male but generally showing slightly less contrast; legs dull to pale brown, feet darker. Female non-breeding is like breeding female, but feathers tipped with buff. Juvenile resembles non-breeding adult, but may have dark brown back and crown; bill grey-brown, legs and feet flesh-coloured. VOICE. Song, often in flight, a musical warble generally lasting for 2–3 seconds, contains 7–8 phrases, each composed of several notes, and has qualities of Western Meadowlark (*Sturnella neglecta*) song. Flight call a distinctive "til-lip", first syllable accented; call a whistled "wheer" or rattling "trip-ri-rip" or "tzip".

Habitat. Breeds in arid short-grass or mixed-grass prairie that has been recently grazed, burnt or mowed; prefers areas where litter accumulation minimal; dominant plant species include rough fescue (*Festuca scabrella*), blue grama grass (*Bouteloua gracilis*), needlegrass (*Stipa*) and wheatgrass (*Agropyron*), interspersed with sage (*Artemisia*), cactus (*Opuntia*), snowberry (*Symphoricarpos*) and American silverberry (*Eleagnus commutata*). Nests also in pastures with domesticated grasses and mowed areas, such as airstrips, but prefers native prairie. Where sympatric with *Rhynchophanes mccownii*, present species usually occupies more mesic areas with denser and often taller grass. On migration and in winter, generally found in native grasslands, xeric grasslands where most vegetation less than 0·5 m tall, often interspersed with shrubs. In Texas (in winter), often uses cultivated fields, and winter flocks tend to be found around isolated sources of water. Sea-level to 2500 m.

Food and Feeding. Diet in breeding season in Colorado 28% seeds (mainly of grasses), 51% crickets and grasshoppers (Orthoptera), 19% beetles (Coleoptera, especially of families Curculionidae and Chrysomelidae), and small numbers of spiders (Araneae) and leafhoppers (Homoptera). On migration and in winter feeds mainly or entirely on seeds, including those of wheat (*Triticum*), sunflowers (*Helianthus*), *Aristida* and pigweed (*Amaranthus*). Forages principally on or near ground or low in vegetation; generally by walking and picking up insects and seeds, but also gleans insects from vegetation, and rarely makes flycatching sallies. In non-breeding season forms small to medium-sized flocks.

Breeding. Season early May to early Aug; often double-brooded, occasionally three broods. Monogamous; partners sometimes remain together for consecutive breeding seasons. Male–male and female–female aggression common, as are extra-pair copulations. Males arrive on breeding grounds 1–2 weeks earlier than females, at first in small flocks, but soon begin to sing and defend a territory; male sings in flight display, while descending with wings spread. Nest built by female alone, sometimes taking only 4 days, a cup made largely from dry grass, lining may include hair and feathers, placed on ground under grass clump, often adjacent to a pat of cattle dung. Clutch 3–5 eggs, rarely 2–6 (67% of more than 400 nests studied had 4-egg clutches), variably whitish, greyish or pale buffy, marked with scrawls, splotches or spots in brown, purplish or brick-red; incubation by female, period 10–12·5 days (in cold summer can take up to 15 days); chicks fed by both parents, leave nest at 9–14 days (commonly 10 days); unable to fly, but may walk quickly through grass, acquire ability to fly c. 2 days after leaving nest. Nests parasitized rarely by Brown-headed Cowbird (*Molothrus ater*).

Movements. Migratory; moves mainly through W & C Prairies and Great Plains to non-breeding grounds from S USA S to Zacatecas region of Mexico (occasionally S to Puebla, Veracruz and México). Spring migration from Feb through Apr or early May. Vacates wintering areas in Mexico by early Apr, although N-bound migration begins at least by early Mar, if not late Feb; in S Arizona peak N passage in Mar, some remaining into May, and timing similar in New Mexico, but in Texas peak spring movement in mid-Apr; farther N peak through Oklahoma and Kansas in Mar. In Colorado and Wyoming peak arrival in mid-Apr, in Saskatchewan and Manitoba mid-Apr through early May; males migrate earlier than females. Leaves breeding grounds mid-Sept through early Oct, peak passage in Canadian Prairies and in N USA during middle or late Sept, and arrival on wintering ground Oct to early Dec. Rare but regular migrant in California from Aug through mid-Dec, peak late Oct. Migrates singly or in flocks; sometimes during stopover found with Horned Larks (*Eremophila alpestris*) and occasionally with other longspurs. Vagrants recorded NE to Newfoundland, mainly during Apr (perhaps when easiest to detect, in summer plumage); also in Pacific Northwest.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Classified as "Declining" in the USA (Yellow WatchList priority species for conservation). Often common or very common in appropriate habitat. Estimated global population 5,600,000 mature individuals. Has suffered significant decrease since c. 1970, with 68·8% decline over 40 years. Historic breeding range in USA extended S through Kansas, Nebraska and Minnesota, but now only very local in those states; change in distribution appears to reflect destruction of native grasses. This species does not nest in cultivated fields. Breeding densities much higher in grazed pastures than in ungrazed ones, but overgrazing may reduce its numbers. On migration generally found in native grasslands, and contraction of wintering range in Texas may reflect a general decrease in abundance and/or degradation of habitat.

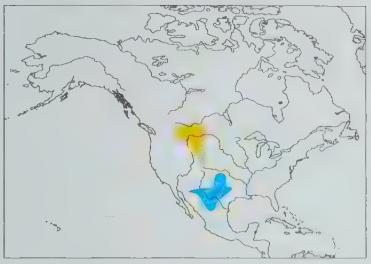
Genus *RHYNCHOPHANES* S. F. Baird, 1858

4. McCown's Longspur

Rhynchophanes mccownii



French: Plectrophane de McCown **Spanish**: Escribano de McCown
German: Schwarzbrust-Spornammer

Taxonomy. *Plectrophanes mccownii* Lawrence, 1851, high prairies of western Texas, USA.

Sometimes placed in genus *Calcarius*, and has hybridized with *Calcarius ornatus*, but apparently is closer in affinities to *Plectrophanax*. Has been suggested that those two genera be placed with present genus in a separate family, Calcariidae. Monotypic.

Distribution. Breeds from S Canada (SE Alberta and SC Saskatchewan) S in USA to C Montana, extreme SE Idaho, E Wyoming, NE Colorado and NW Nebraska. Winters in SE California (rare), C & SE Arizona, C New Mexico, WC Kansas and C Oklahoma and W & SC Texas, and N Mexico (S to N Durango, occasionally Zacatecas).

Descriptive notes. 14–16 cm; male average 26·7 g, female average 24·7 g. Medium-sized short-tailed longspur with extensive white in tail, large conical bill. Male breeding has forehead and anterior part of crown black (depending on wear), face whitish, whitest on eyelids and supercilium, ear-coverts grey, often with some black forming a postocular stripe, black submoustachial stripe; nape grey with some brownish streaks; mantle, scapulars and back brown with pale edges, rump and uppertail-coverts greyish with darker centres, uppertail-coverts long (extending half-way down tail); tail with central feather pair brown, outermost pair white, others white with brown tips; lesser upperwing-coverts grey, median coverts chestnut, greater coverts brown with paler edges and whitish-buff tips, tertials dark brown with pale edges; chin and throat white; breast with crescent-shaped black patch, flanks greyish-white, undertail-coverts white; iris brown or black; bill black; legs grey, light brown or flesh-coloured. Male non-breeding has black areas on head and breast concealed by brown feather tips; breeding plumage acquired by wear. Female breeding has crown greyish-brown with indistinct brown streaks, supercilium whitish-buff, eyestripe and submoustachial

stripe greyish-brown; ear-coverts whitish-buff, becoming brown towards neck; mantle and back brown with dark brown feather centres (giving streaked appearance), rump and uppertail-coverts brown; tail pattern as on male; upperwing brown, varying amounts of cinnamon in lesser and median coverts (apparently varies with age), inner webs of flight-feathers whitish; throat buffy to pale grey, breastband greyish with pale flecking, belly pale; bill horn-yellow to pale, dull pinkish with some dusky, often on tip and culmen. Female non-breeding is similar, but paler. Juvenile is like non-breeding female, but distinctly streaked on breast and flanks. Voice. Male territorial song, generally given in display-flight, sometimes from perch on fence or rock, a distinctive warbling, musical "see see see mee see me hear me hear me see". Flight call a dry rattle, "chip-pur-r-r-r"; call note a distinctive "pink", reminiscent of calls of Bobolink (*Dolichonyx oryzivorus*).

Habitat. Breeds in sparse, arid short-grass prairie, typically in mix of short-grass species (e.g. *Bouteloua*, *Buchloe*) interspersed with cactus (*Opuntia*) and some taller grasses (e.g. *Aristida*, *Agropyron*, *Stipa*) and shrubs; sometimes found in fallow fields. In winter, typically in overgrazed short-grass prairie mixed with other grasses (vegetation height less than 0·5 m). Sea-level to 2500 m.

Food and Feeding. On breeding grounds in Saskatchewan seeds of various sorts (e.g. *Chenopodium*, *Carex*, *Avena* and *Triticum*) make up bulk of diet, augmented with ants (Formicidae) and grasshoppers (Orthoptera), which account for 23% of diet in Aug. Primarily granivorous in winter. Forages principally on or near ground or low in vegetation. Runs and hops; stalks, gleans and occasionally hawks larger insects such as grasshoppers.

Breeding. Season May–Jul; second brood often attempted, may be started as early as late Jun. Monogamous; rarely bigamous. Males arrive on breeding grounds in small flocks, soon begin to display and defend a territory; male has elaborate, stiff-winged song flight during which he parachutes down with wings held up in V-shape (flight display distinctive, even from a distance). Female chooses nest-site, male will work to expand his territory if site slightly outside it; female constructs nest, work may require 2 days, nest cup-shaped, made from dry grass stems, twigs or lichen, lining includes softer grasses, hair and feathers, placed in depression on ground usually adjacent to clump of grass or other vegetation such as cactus (*Opuntia*) or shrub e.g. rabbitbrush (*Chrysothamnus*) or horsebrush (*Tetradymia*). Clutch 2–5 eggs (usually 3 in S part of range, 3–4 in N), whitish to pale olive, marked with brown, chestnut, rust-coloured or purplish scrawls, spots or splotches, sometimes evenly, sometimes concentrated on wide end; incubation by female, period 12 days; nestling period 10 days; young run about through grasses, require further 2–3 days before able to fly a short distance. Nests parasitized very rarely by Brown-headed Cowbird (*Molothrus ater*), and no known case of successful raising of cowbird young.

Movements. Migratory, moving through Great Plains. Spring migration from late Feb through Apr; males migrate up to 2 weeks earlier than females. Departure from wintering grounds begins as early as mid-Feb, with peak in early Mar; timing seems to be relatively constant throughout winter range, although departure may be slightly later in Texas than in New Mexico and Arizona; some may linger in wintering areas into Apr or, exceptionally, early May. Arrival on breeding grounds by late Mar in Colorado, peak in early Apr; in Canadian Prairies later, from mid-Apr, with peak early May. In autumn, leaves Saskatchewan from early Aug through Sept, some remaining into early Oct, and departures farther S (in Colorado) are from early to middle Oct; reach wintering grounds as early as late Sept in New Mexico, early to late Oct in Arizona and Texas, and Nov in N Mexico. Recorded as casual N & W to S British Columbia, Idaho, Nevada, N Arizona and Utah, and E to S Manitoba, Minnesota, Indiana, Missouri and E Texas; accidental in Michigan, New York, Massachusetts and Louisiana. Migrates in flocks, at stopover sites often with Horned Larks (*Eremophila alpestris*) and occasionally with other longspurs.

Status and Conservation. Not globally threatened. Locally common. Has reasonably large range, within which population estimated at 1,100,000 mature individuals. Although locally common in appropriate habitat, this species' range size and population numbers have decreased as a result of habitat destruction. In winter range, has declined in numbers in Arizona, but can still be found in SE part of that state.

Bibliography. Anon. (1998), Armani (1985), Beadle & Rising (2002), DuBois (1923), Hellmayr (1938), Howell & Webb (1995), Hubbard (1972a), Klicka *et al.* (2000), McCarthy (2006), Mickey (1943), Miller *et al.* (1957), Oberholser (1974), Phillips *et al.* (1964), Pyle (1997), Ridgway (1901), Rising & Beadle (1996), Russell & Monson (1998), Salt & Salt (1976), Snyder & Bly (2009), With (1994a, 1994b).

Genus *PLECTROPHENAX* Stejneger, 1882

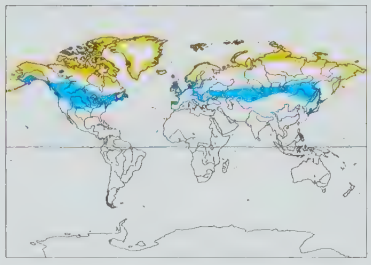
5. Snow Bunting

Plectrophenax nivalis

French: Plectrophane des neiges **German**: Schneeammer **Spanish**: Escribano Nival

Taxonomy. *Emberiza nivalis* Linnaeus, 1758, Lapland.

Molecular studies indicate that genus is closely related to *Calcarius*, and also appears to be a sister-taxon to *Rhynchophanes*; has been suggested that these three genera be placed in a separate family, Calcariidae. Often considered conspecific with *P. hyperboreus*, but juvenile plumages differ; also, interbreeding between the two is minimal, latter arriving on restricted breeding grounds earlier and apparently occupying most/all of suitable breeding sites. Geographical variation not well understood and complicated by high degree of individual variation; ranges listed below tentative, and review desirable. Nominate race intergrades with *townsendi* in E Aleutian Is. Four subspecies recognized.



Subspecies and Distribution.

P. n. nivalis (Linnaeus, 1758) – breeds in N North America from St Lawrence I and coast of Alaska (including E Aleutian Is) E across N Canada (S to N Yukon, NW Mackenzie, C Northwest Territories, C Nunavut, Southampton I, Belcher Is, N Quebec and N Labrador) to coasts of Greenland, and N Scotland, Svalbard, and mountains of W & N Fennoscandia E to Kola Peninsula; non-breeding from SW Alaska and S Canada (NW British Columbia E to Manitoba, Ontario, S Labrador and Newfoundland) S in USA to NW California, Utah, N New Mexico, Kansas, Ohio and Virginia (occasionally farther S on Atlantic coast) and, in Palearctic, British Is and N France E to S Scandinavia, Germany, Poland and S European Russia (occasionally S to Mediterranean and E to Asia Minor).

P. n. insulae Salomonsen, 1931 – Iceland, possibly also N Scotland; non-breeding occasionally S to Faeroe Is and Shetland Is.

P. n. vlasowae Portenko, 1937 – breeds NE European Russia E through Siberia (including Severnaya Zemlya, New Siberian Is and Wrangel I) to Bering Strait and S to N Shelekhova Gulf and E Kamchatka; non-breeding in C & E Asia S to N Caspian region, Altai, Mongolia, Transbaikalia, NE China, Sakhalin I, Kuril Is, occasionally to N Japan (Hokkaido) and Korea.

P. n. townsendi Ridgway, 1887 – Commander Is, Pribilofs, and Aleutian Is.

Descriptive notes. 14–18 cm; 18–56 g. A large emberizid with large conical bill and relatively short, notched tail. Male nominate race breeding has head, neck and entire underparts white, sometimes some black in crown; upperparts black, back sometimes mottled with brown, rump and shorter uppertail-coverts white, central rump sometimes mottled with black; three outer pairs of rectrices white, thinly tipped black on outer web, three central pairs black with pale fringes; most of upperwing white, alula feathers black, primaries black with white bases, tertials black; iris dark brown; bill black; legs dark grey or black. Male non-breeding has white areas washed with rusty brown, particularly on nape, crown, ear-coverts and breast, black feathers on back edged with frosty brown, bill yellowish; breeding plumage acquired mostly through wear (although has limited pre-breeding moult). Female smaller than male; in breeding plumage has crown and rear of head usually more dusky than male, upperparts duller, often brownish, dark feathers of upperparts with pale fringes, and somewhat less white in wing; in very worn plumage resembles male. Female non-breeding is similar to non-breeding male. Juvenile (Jul–Aug) has head and breast greyish-brown, throat sometimes paler, pale eyering and narrow moustachial stripe, upperparts olive-grey, back streaked darker grey, upperwing dark grey to blackish, coverts tipped white (male with white more extensive), inner primaries with white at bases, secondaries white with dark tips (white more extensive on male), lower underparts whitish with pink to greyish-buff wash, bill yellowish; first-winter male like adult, but juvenile wing, greater coverts and tail feathers retained; first-winter female like adult, but with duller secondaries, buffier head and browner underparts. Races vary mainly in coloration of feather fringes (fresh plumage), extent of black, and size, but differences not great: *insulae* is darker than others, has more extensive black in wing; *vlasowae* is somewhat paler than nominate, has more white on rump; *townsendi* is similar to previous, but a little larger and with longer bill. Voice. Song, often in flight display, a short, musical "turee turee turee turiwee". Call notes a descending "cheeew" and "tweet"; buzzing "trr" from flocks; also a soft short rattle.

Habitat. Treeless, uncultivated barren rocky terrain, often near snow, also sea cliffs; often nests near or even in human settlements. In winter found in open fields, shingle beaches, saltmarshes, sand dunes, and stubble fields. Sea-level to 2300 m.

Food and Feeding. Mainly seeds, but in breeding season also small arthropods. Young fed only with invertebrates, including variety of insects e.g. or orders Plecoptera, Orthoptera, Dermaptera, Hemiptera, Lepidoptera, Trichoptera, Diptera (e.g. Tipulidae) Coleoptera and others, also worms (Oligochaeta) and spiders (Araneae). Stomachs of birds from North America (Hudson Bay and Pribilof Is) contained 29·6% animal items and 70·4% vegetable matter. Generally forages on or near ground or low in vegetation. Walks, runs, and occasionally hops; will sally to catch flying insects. Sometimes perches in trees or on fences, and burrows into snow. In non-breeding season in flocks of tens to hundreds of individuals, but also singly and in twos and threes; sometimes associates with other species, e.g. Horned Lark (*Eremophila alpestris*).

Breeding. Pair formation by late May in Greenland, breeds from mid-May through Jul in Iceland, begins breeding in late May in Scotland, and pair formation in early Jun in Canada (Nunavut); timing of arrival, pairing and egg-laying dependent on weather conditions, and sometimes significantly later in years with cold spring; may be double-brooded (varies geographically and from year to year), but mostly single-brooded in Arctic. Monogamous. Males arrive in breeding area as much as 3–4 weeks before females, remain in flocks for two weeks before breaking out into territorial defence. Male has elaborate aerial display during which he rises to 15 m, then glides into wind with wings held in a "V" above body while singing. Both sexes search for nest-site, only female builds nest, a thick cup of dry grass and moss, lined with finer grasses, fur and feathers, commonly those of ptarmigan (*Lagopus*), placed in variety of places, commonly in crevice or crag in rocks, but will also use artificial site such as building, nestbox, tin can, grave, human skull and the like. Clutch 2–8 eggs, most commonly 5, white to pale green or pale blue and marked with brownish, purplish or reddish spots, scrawls and splotches (usually concentrated at large end); incubation by female, often fed on nest by male, period 10–15 days, most commonly 12–13 days; nestling period 13 days.

Movements. Most populations migratory; females move farther S than males. Males move N in spring considerably (3–6 weeks) earlier than females, older males earlier than young males. Much of the migration not well known (occurs far to N, where few observers), although ringing studies reveal that those breeding in W & SE Greenland winter in North America, migrate across Davis Strait, down coast of E North America, and then W along St Lawrence R; in contrast, those breeding in E Greenland winter in Eurasia, and NE Greenland birds winter on steppes in Russia, staging in N Norway. Migration in C North America thought to occur along broad front, with no particular concentration points as birds move N; little known about W coast migrants. Arrival in low Arctic in mid-Mar and high Arctic in early Apr, although great variation from year to year depending on weather conditions; delays in arrival in Greenland as long as one month in particularly cold springs. Departure from breeding grounds in Sept to early Nov, arrival in wintering areas from as early as mid-Oct, while S wintering sites may not be reached until Nov. In Palearctic, most birds move S to winter in coastal areas, some reaching N England, N Germany, etc.; some birds winter in N mountains; some Greenland breeders move to Iceland and N coasts of Ireland. Nominate race recorded as accidental in Hawaiian Is, S USA (NW Arizona, Texas), Bahamas and N Africa. Migrates in loose flocks, sometimes with Horned Larks (*Eremophila alpestris*) and *Calcarius* species.

Status and Conservation. Not globally threatened. Common or very common in appropriate habitat. Has extremely large circumpolar range, within which total population of mature individuals estimated at 40,000,000. Appears to have suffered some decline during last 30–40 years, but still very common. In Europe, noticeable decrease in numbers wintering in coastal areas of S North Sea since c. 1970 believed due to destruction of saltmarshes (preferred foraging habitat of the species) caused by huge embankment projects combined with intensification of grazing; from 1990s onwards, grazing greatly reduced and no further embankment projects planned, and numbers of this and other species in S North Sea have begun to recover.

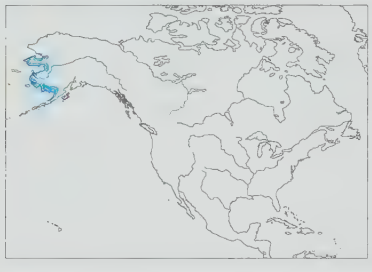
6. McKay's Bunting



Plectrophenax hyperboreus

French: Plectrophane blanc **German**: Beringschneeammer **Spanish**: Escribano de McKay

Taxonomy. *Plectrophenax hyperboreus* Ridgway, 1884, St Michael Island, south shore of Norton Sound, Alaska, USA.

Molecular studies indicate that genus is closely related to *Calcarius*, and also appears to be a sister-taxon to *Rhynchophanes*; has been suggested that these three genera be placed in a separate family, Calcariidae. Often considered conspecific with *P. nivalis*, but juvenile plumages differ; also, inter-breeding between the two is minimal, present species arriving on restricted breeding grounds earlier and apparently occupying most/all of suitable breeding sites. Monotypic.

Distribution. Breeds on islands of Bering Sea, mainly on Hall I and St Matthew I, rarely St Paul (Pribilofs) and St Lawrence I; non-breeding on coast of W & SW Alaska.

Descriptive notes. 15–19 cm; c. 38–62 g. A large bunting with large bill and relatively short, notched tail. Male breeding is entirely white, except for partly black tertials, tips of primaries and tips of central two pairs of rectrices (often centres of some scapulars also black); iris dark brown to black; bill black; legs dark brown or black. Male non-breeding is similar, but slightly washed with rusty brown, especially on crown, ear-coverts and breast. Female is smaller than male; breeding plumage similar, but crown speckled dusky, back streaked with black, alula black, more black on central rectrices (dusky to base), other rectrices sometimes dusky on inner webs. Female non-breeding is like non-breeding male, but perhaps darker. Juvenile (Jul–Aug) has head to breast greyish, paler on throat and moustachial stripe, upperparts blackish with broad buffish feather edges, white in wing and tail as on adult but less extensive, flanks pinkish, belly white, bill yellowish; first-winter male like non-breeding adult, but more rusty on upperparts and tertials, a little more black in wing and tail; first-winter female like adult, but darker and duller, with less white. Voice. Song a low warbling; calls include soft rattle and whistled descending "cheew"; apparently very like voice of *P. nivalis*.

Habitat. Breeds on beaches and rocky talus slopes, and on shores of tundra pools; sea-level to 490 m. In winter primarily on coast.

Food and Feeding. Little known. Probably eats seeds in winter, and insects and other invertebrates when available. Generally forages on or near ground or low in vegetation. In small groups; in flocks of 50–60 individuals in non-breeding season.

Breeding. Little known. Pair formation occurs during May, nest-building and laying by late Jun, young hatch by start of Jul (sometimes end of Jun), and fledglings present by mid-Jul or a little earlier; perhaps double-brooded on occasion. Probably monogamous. Nest usually placed in crevice or space under or between rocks, but sometimes in artificial site, including in whale mandible and even in woodpecker (Picidae) hole in driftwood on beach. Clutch 3–5 eggs, commonly 4, pale greenish with brown spots. No other information.

Movements. Migratory; winters mainly in W & SW Alaska. Leaves breeding grounds by early Oct, heads E and may stop at Nunivak I, before continuing to coast of mainland Alaska; disperses S & E along coast. Some fly through Pribilof Is on passage to and from Alaskan Peninsula. Returns to nesting islands in early Mar (an earlier migrant than *P. nivalis*), but many remain in wintering areas into early Apr; some may make stopover in spring at Hooper Bay, on W Alaskan coast directly E of breeding islands. Recorded casually S to Aleutians and S coastal Alaska; also in Chukotka Peninsula, in extreme NE Russia. Vagrants recorded S to NE USA (Washington and Oregon).

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Classified as "Rare" in the USA (Yellow WatchList priority species for conservation). Restricted-range species: present in Eastern Bering Sea Islands Secondary Area. Abundant within its limited breeding range. Breeding range tiny: St Matthew I is c. 350 km², and Hall I only c. 16 km² in extent; species breeds only rarely on other islands. Global population has been put at c. 6000 mature individuals. In recent careful study, however, combined populations on Hall and St Matthew estimated as totalling more than 31,000 individuals. Could be vulnerable to accidental/deliberate introduction of invasive predators such as rats (*Rattus*), foxes (*Vulpes*) or weasels (*Mustela*), or to deliberate introduction of reindeer (*Rangifer tarandus*); reindeer introduced on St Matthew in 1944 destroyed much of the native vegetation before they died out, and current breeding densities of this bunting still lower on St Matthew than on Hall. Potential threats also include oil development, contaminants, and effects of climate change. Both Hall I and St Matthew I are protected within Alaska Maritime National Wildlife Refuge; the species non-breeding range includes parts of Yukon Delta and Togiak National Wildlife Refuges.

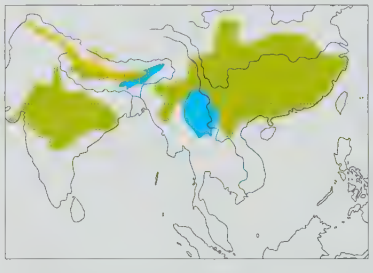
PLATE 40 ➤



Genus *MELOPHUS* Swainson, 1837

7. Crested Bunting

Melophus lathami

French: Bruant huppé **German**: Haubenammer **Spanish**: Escribano Crestado

Taxonomy. *Emberiza lathami* J. E. Gray, 1831, Guangzhou, Guangdong, China.
No obvious affinities. Recent molecular studies suggest that genus is very close to *Emberiza*, and may be better subsumed within it; on the other hand, striking plumage features, especially of male, favour retention of a monotypic genus. Quite marked difference between shiny blue-black and rusty-chestnut males in W part of range (India) and dull brownish-black and orange-rufous males in E China, but extensive intervening areas inhabited by intermediates; Indian populations sometimes separated as race *subcristata* (described from the Deccan, in SC India), but delimitation of any clear races is difficult. Monotypic.
Distribution. S slopes of Himalayas from NE Pakistan (Murree) E to NE India (Assam, Meghalaya and Manipur), also C India (from E Rajasthan, S Gujarat, SW Maharashtra, N Andhra Pradesh and E Madhya Pradesh E to S Bihar), and S China (from Red Basin of Sichuan E, chiefly S of 30° N, to Anhui and Zhejiang, S to Yunnan, Guangxi and Guangdong) S to Myanmar, N & C Laos and N Vietnam (Tonkin). Also W & NW Thailand in non-breeding season.
Descriptive notes. 16 cm; 20–26 g. Distinctive, elongate bunting with prominent crest and plain, almost round-tipped tail; rufous wings in all plumages. Male breeding has elongated forecrown feathers (can be erected into prominent crest); entire head and body shiny black or brownish-black, may have some rusty-rufous on thigh, uppertail- and undertail-coverts; wing and tail bright rusty-rufous, flight-feathers usually with dusky tips; iris dark brown; bill sometimes almost wholly pink in breeding season, but often with grey culmen or upper mandible, or wholly black; legs light pinkish-brown to dark purplish-brown. Male non-breeding (fresh plumage) has buffish-grey fringes on black body feathers. Second-winter male is much as adult, but with black tips on primary coverts. Female has distinctly shorter crest than male, overall body coloration dull buffy-olive, diffusely streaked darker, streaking boldest on breast, mantle and scapulars, finest and most intense on head; pale buffy eyering; rufous in wing and tail (particularly on more exposed outer webs) tends to become faded with wear, but such individuals exhibit brighter rufous in flight (as normally concealed rufous of inner webs revealed). Female non-breeding (fresh plumage) is sandy brown, with streaking bolder and more defined, belly weakly washed with pale yellow, which becomes cinnamon-buff on undertail-coverts. First-winter female resembles adult, but duller, with only weak rufous colour in wing, and more coarsely streaked overall. Juvenile of both sexes resembles adult female, but crest very short and inconspicuous, breast more boldly streaked, and overall colour tones buffer.

Voice. Simple song, from prominent perch such as very top of tree, bush, rock outcrop or roof of building, a repeated series of 2–3 pairs of notes, starting with a couple of subdued grating ones, followed by a pair of lower, mellower notes, with variable finish of 2 or 3 often descending notes, has been transcribed as "tsri-tsri-tsi-tsu-tsu", another version as "which which which-whi-wheee-which" with emphasis on the "wheee"; these variable little phrases can be repeated *ad nauseam*. Typical call a soft, slightly squeaked "tip", "pink" or "tlip", given somewhat more forcefully in flight.
Habitat. Open dry grassy or rocky hillsides and terraced cultivation with scattered bushes and rock outcrops, from foothills to 2440 m in summer. Most descend lower in winter, then favouring grasslands, both in cultivated areas and amid dry scrub-jungle down to edge of plains.
Food and Feeding. Chiefly small grass seeds of various kinds, including fallen grains and some weed seeds. Also, has been observed to practise flycatching during emergences of alate ants (Formicidae). Nestling diet includes insect larvae. Feeds on ground. Particularly fond of feeding at roadsides and in cart tracks through grassland, especially where grassland has been burnt over; flies up when disturbed, perching near top of tall grasses, or bush, dropping back down when potential danger has passed. Carriage on ground normally rather upright, with tail pressed down; male also adopts rather flat-backed, horizontal stance with tail slightly raised and spread at tip. Generally quite confiding. In pairs or in small parties of up to ten individuals; groups may assemble temporarily at drinking locations in dry weather or for winter roosts. Rarely found in large flocks (unlike some other buntings in winter), but flocks of up to 150 individuals reported. Roosts in dense thickets, in hedges, and in stands of "elephant-grass" (collection of several species of tall

grass, rather than a specific one); often shares roost thickets with other small birds such as munias (*Lonchura*) and Olive-backed (*Anthus hogdsoni*) and Tree Pipits (*Anthus trivialis*).
Breeding. Season varies, coinciding with local wet seasons: egg-laying late Apr to Jun in E China, Jul–Aug in Pakistan and NW India and Jun–Jul in W India (Rajasthan); Apr repeatedly quoted for C Nepal, but this seems early for W populations and requires confirmation; single-brooded. Monogamous. Solitary nester. Nest built by female, male bringing some materials, a cup of fine rootlets, animal hair, mosses and dried grasses, placed in hollow on ground, under rock or in crevice near foot of bank or stone wall, typically concealed by clump of ferns or grasses; very rarely low down, not protected by bank, in *Lantana* thicket. Clutch 3–5 eggs (mean 3), white with greenish tinge and with speckles and blotches in red, brown and purple, mainly at broad end; incubation by female, male helps in feeding young; no information on duration of incubation and nestling periods. Nest occasionally parasitized by Common Cuckoo (*Cuculus canorus*).
Movements. Resident and altitudinal migrant. Resident in low-lying hills over much of range, merely withdrawing into sheltered valleys in winter. In Himalayan region (e.g. Nepal) a summer visitor above 1200 m, arriving in breeding areas during Apr and May, returning to lower elevations by Oct. Recorded in Taiwan as vagrant or, possibly, escaped cagebird.
Status and Conservation. Not globally threatened. Common to abundant, though somewhat localized, over most of extensive range. In Pakistan and Kashmir decidedly uncommon; occurrence in Bangladesh remains to be proven; elsewhere it seems reasonably numerous. Benefits from man's activities, finding terraced cultivation and deforested hillsides much to its liking. Unlikely to cause agricultural damage, as not known to strip out ears of corn.
Bibliography. Ali (1949, 1962), Ali & Ripley (1974), Alström *et al.* (2008), Armani (1985), Bates & Lowther (1952), Bhardwaj *et al.* (2008), Byers, Olsson & Curson (1995), Dharmakumarsinhji (1972), Grimmett *et al.* (1998), La Touche (1925–1930), MacKinnon & Phillipps (2000), Roberts (1992), Shivrajkumar (1954), Smythies (1986), Stuart Baker (1926), Tell (1983), Ticehurst (1932).

Genus *LATOUCHEORNIS* Bangs, 1931

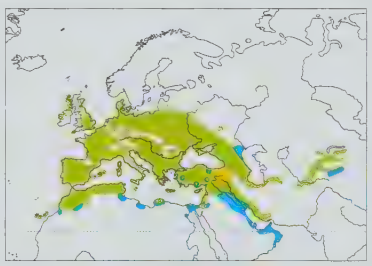
8. **Slaty Bunting**

Latoucheornis siemsseni

French: Bruant bleu **German**: Blauammer **Spanish**: Escribano Azul
Other common names: Fukien Slaty Bunting, Blue Bunting, Chinese/Fukien (Blue) Bunting, La Touche's Bunting

Taxonomy. *Junco siemsseni* G. H. Martens, 1906, Mia River region, Fuzhou, Fujian, China.
Originally described in genus *Junco*, male plumage superficially resembling that of "slate-coloured" populations of *Junco hyemalis*, but was soon placed in a monotypic genus. Recent phylogenetic analyses, however, indicate that this species is, surprisingly, a sister-species of *Emberiza elegans*. Differs from *Emberiza* in unstreaked male plumage and very rufous female plumage, very small bill, and strangely shaped tail feathers, but recent molecular studies indicated that differences from that genus are minor and that present genus could well be merged with *Emberiza*. Monotypic.
Distribution. Breeds in C China in S Gansu and S Shaanxi (from Taibai Shan) S to W Sichuan (Nan Chuan range and valleys at E edge of Tibetan Plateau; probably also in NE Sichuan); probably also farther E, in Anhui (Huang Shan). In non-breeding season widely recorded at lower elevations in Sichuan, W Hubei, Anhui, Yunnan, Guizhou, Fujian and N Guangdong.

Descriptive notes. 13 cm; c. 20 g. Highly distinctive plumages; tail feathers unusual, relatively broad towards tip, but tapering to narrow base, bill comparatively small and neat, and hind claw relatively strongly arched. Male is almost wholly dark slate-blue, with diffuse dusky lores and relatively inconspicuous white centre of belly and undertail-coverts; upperwing darker, having blackish feather centres (most apparent on tertials) and dark blue fringes, bases of inner webs of secondaries white (sometimes visible in flight); tail dark blue, extensive white on inner web of outermost feather; iris dark brown; bill black, in winter often with whiter cutting edges or lower mandible (significance of which unclear); legs flesh-pink. First-winter male is similar to adult, but when plumage fresh body feathers have narrow olive-brown fringes and greater upperwing-coverts white tips (forming narrow bar). Female has whole head and foreparts of body brownish-rufous, brightest rufous on crown, shading into olive-brown on mantle and uppertail-coverts, with rump greyer; breast rufous with inconspicuous fine pale shaft streaks, shading into olive-brown on flanks, becoming white on central belly and undertail-coverts; upperwing dull brown with darker feather centres, tertial centres darkest; fringes and tips of wing-coverts rufous (two inconspicuous wingbars), bases of inner webs of secondaries white; tail dark brown, extensive white on inner web of outermost feather; bare parts as for male. First-winter female is similar to adult, but when plumage fresh has more clearly streaked mantle and scapulars, contrasting with paler rump and darker uppertail-coverts; tips of wing-coverts paler rufous, forming two narrower, paler bars than when adult. Juvenile is similar to first-winter female, but head and throat duller rufous, inconspicuously finely streaked darker, ear-coverts somewhat paler and greyer, outer webs of tertials contrasting buffy white, tips of greater coverts and (less obviously) median coverts pale buff (forming narrow bars), white of central belly and undertail-coverts obscured by greyish mottling. Voice. Song rather high in pitch and variable in content, containing parid-like phrases and snatches recalling song of Tree Pipit (*Anthus trivialis*): most frequent type begins with high-pitched whistled notes, before breaking into a twitter and terminating in another high-pitched note, has been transcribed as "ziii-ziiiu-tzittzittzittzit hee"; another song a less varied "siii tsiu zhiu zhiu zhiu zhiu", and others beginning with a rapid trill have been transcribed as "ze-ze-ze-ze-swee twiitwit" and "tze-tze-tze tze teez, teez, teez". Typical call a sharp "zick" or doubled "zick-zick".
Habitat. Breeds in subtropical valley forests in hills and mountains, chiefly between 1500 m and 2100 m; favours vicinity of bamboo thickets in secondary forest and scrubby cover of degraded forest. Descends to foothills in winter, then found at 500–1700 m, where takes advantage of human activities by foraging about villages, and even city parks.
Food and Feeding. Few data. Seemingly chiefly small invertebrates, certainly so in breeding season, when recorded as taking small beetles (Coleoptera), ants (Formicidae), cicadas (Cicadidae) and their larvae, as well as some small plant seeds. In non-breeding season small parties recorded in vicinity of villages, gathering to feed on kitchen waste. Forages on ground, keeping very much under cover.
Breeding. Virtually undocumented. Nest-building reported in early Jun in Sichuan, but perhaps begins as early as early May in some areas; singing individual in Dabie Shan (NE Hubei/SW Anhui) in mid-Apr was probably on its breeding grounds. Presumed to be monogamous. Observation of pair carrying nesting materials indicated that nest was c. 1·5 m from ground in shrubby riverside bushes.
Movements. Altitudinal and short-distance migrant. Post-breeding descent to much lower elevations than those occupied during breeding season.
Status and Conservation. Not globally threatened. Restricted-range species: present in Central Sichuan Mountains EBA. Despite being relatively little studied, this bunting is not considered to approach thresholds for even threatened status. Has extensive range in Sichuan, and evidently breeds elsewhere (S Shaanxi, and in Huang Shan of Anhui). Preference for degraded secondary forest and no obvious decline in wintering numbers suggest stable population. No doubt easily overlooked because of its relatively skulking habits and high-pitched simple song.
Bibliography. Alström *et al.* (2008), Armani (1985), Bangs (1931), Boyd *et al.* (2008), Byers, Olsson & Curson (1995), Cheng Tsohsin (1987), Cheng Tsohsin & Stresemann (1961), Fu Tongsheng *et al.* (1998), Koblik (1993), La Touche (1925–1930), Lewthwaite *et al.* (1996), Liang Gang *et al.* (2008), MacKinnon & Phillipps (2000).



Genus *EMBERIZA* Linnaeus, 1758

9. **Corn Bunting**

Emberiza calandra

French: Bruant proyer **German**: Grauammer **Spanish**: Escribano Triguero
Other common names: Common Bunting

Taxonomy. *Emberiza calandra* Linnaeus, 1758, Sweden.
Often separated in monotypic genus *Miliaria* on account of lack of sexual dimorphism, different moult strategy (the only bunting to have complete post-juvenile moult), and differences in bill structure and tertial pattern; recent molecular studies, however, suggest that genetic differences are so small that placement in monotypic genus not warranted. Geographical variation complicated by local conditions that affect plumage colour tones and intensity of streaking; *clanceyi* tentatively recognized, as its plumage features seem surprisingly constant. Other named races include *thanneri* (described from Tenerife, in Canary Is), *kleinschmidti* (from Malaga, in E Spain), *algeriensis* (from Bône, in Algeria), *graeca* (from Calamata, in Greece), *volhynica* (from Volodymyr-Volynskyi, in NW Ukraine), *sarmatia* (from Askania-Nova, in Kherson Oblast, in S Ukraine) and *ignobilis* (from near Tbilisi, in Georgia), all synonymized with nominate. Species may be better treated as monotypic. Three subspecies tentatively recognised.
Subspecies and Distribution.
E. c. clanceyi R. Meinertzhagen, 1947 – W Scotland (Hebrides) and W Ireland.
E. c. calandra Linnaeus, 1758 – Britain (NE Scotland and parts of England), Denmark, extreme S Sweden and S Latvia S, somewhat patchily, to Iberia and Mediterranean (including most islands), and E to Belarus, Ukraine and S Russia (S to Caucasus region), NW Caspian Sea, Turkey (except SE) and coastal Lebanon and Israel; also N Africa (Morocco E to NW Libya) and Canary Is.
E. c. buturlini H. E. Johansen, 1907 – SE Turkey S to N Israel, E across Syria, Iraq and W & N Iran to Turkmenistan and N Afghanistan, also N through Tajikistan, SE Uzbekistan and Kyrgystan to S Kazakhstan and extreme NW China (extreme W Xinjiang).

Descriptive notes. 17–19 cm; c. 32–67 g. A heavily built, streaky, dull brownish bunting, distinctive in lacking conspicuous white in outer tail and in having bold dark streaking on both upper and underparts; bill stout, mandibles with curving S-shaped cutting edges, strong pale legs. Nominate race has crown, nape and ear-coverts grey-brown to olive-brown, finely streaked darker, ear-coverts slightly warmer brown, paling towards centre; lores and supercilium indistinctly paler, whitish submoustachial stripe also finely streaked; upperparts grey-brown to warm brown with blackish streaking, streaking on rump and uppertail-coverts diffuse and greyer (in flight, weaker streaking makes rump and tail appear distinctly lighter brown than rest of upperparts); upperwing feathers dark brown, edged and tipped buffy or whitish-grey, tertials evenly edged pale (unlike other members of genus, on which pale edge widens towards tip); tail brown, outermost tail feathers with indistinct whitish tips; chin and throat whitish, bordered by narrow dark malar stripe; lines of bold dusky streaks extend from chest over most of whitish or pale buffish underparts, sometimes including undertail-coverts, streaks often coalescing to form blackish blotch at centre of breast; iris dark brown; bill pale yellowish, grey culmen ridge; legs yellowish-pink to light brown. Sexes similar, male significantly larger than female. Juvenile is very like adult, but warmer buff ground colour overall, crown darker at side and paler at centre, giving surprisingly strong pattern, legs clear pinkish or yellowish-pink; this plumage short-lived. Races differ mainly in general plumage tone and in thickness of streaking: *clanceyi* is warmer brown above and quite noticeably washed yellowish-buff on underparts; *buturlini* is decidedly grey-brown and whitish, with less extensive streaking than nominate. Voice. Song a bouncing jumbled outburst, sometimes likened to sound made by jangling of a bunch of keys, 2 or 3 notes followed by hurried discordant delivery of remainder, "tik tik zreeississ", varying in length. In regions where this species has become rare, isolated individuals may sing perfect renditions of *E. citrinella* and even *E. hortulana* songs. Often flies with fluttering wingbeats, legs dangling, between songposts. Typical call a distinctive, clipped click, "pit", rather subdued, most apparent when rapidly repeated 5–6 times; also a fuller "quip".

On following pages: 10. Yellowhammer (*Emberiza citrinella*); 11. Pine Bunting (*Emberiza leucocephalos*).

Habitat. Open rolling grasslands, both in natural steppe and in agricultural land; tolerates scattered bushes, but avoids extensive bushy cover. Locally, found also in heathland and even, as in Germany, around abandoned sewage works and the like. In non-breeding season, often in fallow fields and stubble fields, and roosts often in *Phragmites* reeds. Chiefly in lowlands; reaches 2600 m in subalpine meadows in parts of C Asia.
Food and Feeding. Omnivorous, but chiefly plant seeds. In breeding season especially, diet includes high percentage of invertebrates, primarily small insects, including butterflies (Lepidoptera), also small spiders (Araneae), millipedes (Diplopoda), slugs, snails (Gastropoda) and earthworms (Oligochaeta). Extensive variety of seeds recorded in diet, from those of weeds and grasses, grains of wheat, barley and oats, to winged sycamore (*Acer*) seeds. Typically, feeds on ground, progressing in short hops; has been reported as picking over animal dung, also clumsily flycatching during emergences of flying ants (Formicidae). Sociable, may form flocks of several hundreds, occasionally more than 1000 individuals, outside breeding season in some parts of range. Tends to avoid close proximity of other bunting species; sometimes with *E. citrinella*, but, unlike that species, usually not closely associated with farming settlements in winter.
Breeding. Season often protracted, laying starting relatively late, from late May or early Jun, in NW of range, earlier in S; lowland populations in Israel commence late Feb, whereas those at higher elevations in same part of world begin laying in mid-Mar; one or two broods over most of range, regularly two or three in S England. Usually polygamous, males having up to as many as 18 females in territory, but often monogamous; bond between sexes not close. Nest built entirely by female, a loose construction of grasses, lined with finer grasses and rootlets, placed on ground amid clump of tangled grasses, brambles and arable weeds, or in depression in soil of arable field. Clutch 1–7 eggs, chiefly 4–6, white with light blue to buffish tinge, with diffuse dark speckling and some prominent blotches and scrawls; incubation by female alone, period 12–14 days; chicks fed by female, though male often in attendance, nestling period 9–13 days; young often leave nest before able to fly.
Movements. N & W populations mainly sedentary, as are those of Mediterranean Basin and Canary Is. Otherwise partially migratory, some of those breeding in C & E Europe moving S or SW to N Italy, S France and Spain, some reaching N Africa (Morocco, Libya and Egypt); farther E, C Asian birds move S, reaching Oman, S Iraq, S Iran and W Afghanistan. Autumn migration protracted, but complicated by wandering flocks which move only when cold weather sets in. In Israel two influxes reported, with through passage late Oct to mid-Nov, and arrivals mid-Nov to early Dec primarily of wintering birds. Vagrants have reached Faeroes, Norway (where last bred 1928), Finland, W Saudi Arabia, Pakistan, NW India, coastal Mauritania and NW Senegal.
Status and Conservation. Not globally threatened. Widespread and abundant in much of range. No longer breeds regularly in Norway, Latvia, Estonia and Lithuania; race *clanceyi* virtually extinct in W Ireland, and survives only on the Hebrides, in W Scotland. Has decreased in most European countries since 1930s, decline most apparent since mid-1960s in many places, late 1970s in others. Decrease considered due to intensification of agriculture, including changes in land use, earlier cutting of hay meadows, loss of hedgerows, more extensive use of pesticides, and climate change. Following estimates for W Palearctic populations (territories or pairs): in British Is 75% drop to 20,000 territories during 20 years to 1991; in Ireland sharp drop to fewer than 30 territories by 1993; in Sweden formerly common in S, but fewer than six territories by 1993; 11,000–120,000 pairs in Denmark in 1987 (decrease since then); 100,000–1,000,000 pairs in France in 1970s, stable but some local decreases; 3000–5500 pairs in Belgium in 1990, and decreasing; 20–200 pairs and decreasing in Luxembourg; in Netherlands long decline to 1100 pairs in 1975, 100–200 by 1989; in Germany 21,000–31,000 pairs in 2005, decrease marked, e.g. in Schleswig-Holstein 3000–4000 pairs in 1955 had dropped to 40 by 1987, but recent recolonization (155 pairs in 2010); 50,000–200,000 pairs in Poland; in Czech Republic marked decrease since 1960s, 700–1400 pairs in late 1980s; in Slovakia 4000–8000 pairs in early 1970s, decrease since; in Hungary 8000–12,000 pairs during 1980s; in Switzerland marked decrease to 200–250 pairs by early 1990s; marked decrease in many areas in Austria; in Italy 200,000–600,000 pairs, slight decrease; 100,000–1,000,000 pairs in Croatia; 1000–2000 pairs in Slovenia; 100,000–1,000,000 pairs in Bulgaria; 50,000–60,000 pairs in late 1980s in Romania; 1000–10,000 pairs in European Russia; 100–1000 pairs, stable, in Belarus; 4000–7000 pairs and decreasing in Ukraine; in Moldova 1500–3000 pairs in 1988, some decrease; in Spain 1,440,00–4,300,000 pairs, slight increase; in Canary Is present on most islands, declining; 100,000–1,000,000 pairs in Portugal; 70,000–100,000 pairs in Albania; in Greece 300,000–500,000 pairs, some decrease; in Malta 400–600 birds, decreasing; in Cyprus 40,000–60,000 pairs, stable; 1,000,000–10,000,000 pairs in Turkey; common locally in Azerbaijan; a few thousand pairs in Israel; very few in Jordan, first bred 1990; in Syria common in NW, fewer in E; in Morocco, Algeria and Tunisia common in N, stable. No indication of a decrease in the C Asian populations, but information sparse.

10. Yellowhammer

Emberiza citrinella

French: Bruant jaune **German**: Goldammer **Spanish**: Escribano Cerillo
Other common names: Yellow Bunting; Eastern Yellowhammer (*erythrogenys*)

Taxonomy. *Emberiza citrinella* Linnaeus, 1758, Sweden.
Most closely related to, and perhaps forming a superspecies with, *E. leucocephalos*; sometimes considered conspecific, but the two differ clearly in plumage, as well as in behaviour and osteology, supporting treatment as separate species. Closest species to this pair are *E. stewarti* and *E. cirlus*. Present species and *E. leucocephalos* hybridize extensively in W & C Siberia (across c. 3000 km in taiga and forest-steppe zone from R Ural E to L Baikal), and intensity of interbreeding is increasing, since each species is expanding its breeding range across/towards that of the other; this type of interbreeding has been described as intermediate between occasional hybridization (not influencing gene pools of parent species) and introgressive hybridization (resulting sometimes in local fusion of species). An independent recent analysis of phylogeny supports recognition of two independent species, although cytochrome *b* sequences are very similar, resulting in a strong indication that they are sister-species; sharing of haplotypes even in very distant locations seems to be result of introgression of mitochondrial DNA. An independent alternative study also argues that both species are older than their closest relatives and that mtDNA has recently introgressed between them, most likely as a result of selective sweep. Has been suggested that race *erythrogenys* is only the result of hybridization with *E. leucocephalos*. Nominate race intergrades with *erythrogenys* in a broad zone extending from Baltic Republics, W European Russia and W Belarus S to E Hungary, E & S Balkans and Greece. Three subspecies recognized.

Subspecies and Distribution.
E. c. caliginosa Clancey, 1940 – Ireland, I of Man and Britain (S to Wales and N & W England).
E. c. citrinella Linnaeus, 1758 – Fennoscandia (S from c. 70° N) and SE England S to N Iberia, S France and Italy and E to extreme NW European Russia, Poland, Czech Republic, Hungary and Balkans.
E. c. erythrogenys C. L. Brehm, 1855 – E Europe (from European Russia, C Ukraine and Balkans) E to SC Siberia (Irkutsk) and NC Mongolia (R Selenge), and to c. 64° N, also isolated population in E Black Sea coast region and Caucasus; some migrate S to Turkey, Levant, Iraq, Iran and C Asia, a few to N Italy.
Introduced in New Zealand region.

Descriptive notes. 16–16·5 cm; 20–36·5 g. Rather large bunting. Male nominate race in fresh plumage (Sept–Nov) has yellow head with broad black and olive lateral crownstripe (most of crown feathers yellow, with relatively well-demarcated tiny dark greyish-green spot on tip), more or less diffuse dark border around ear-coverts (appearing broken at upper rear corner); warm brown upperparts streaked blackish, much less streaked on rufous-chestnut rump and uppertail-coverts; edges of primaries with yellow tones, and white in outer rectrices; throat pale yellowish, streaky dark malar stripe; below, yellowish with blackish streaks, especially on breast and rear flanks, with olive chestband and elements of rufous on side of breast and upper flanks; iris dark brown; bill blue-grey, slightly paler below; legs flesh-brown. Male in worn plumage (May–Aug) has head extensively yellow, dark pattern sometimes restricted to narrow blackish streaks above supercilium, often very faint above eye, sometimes restricted to small dark area at base of bill and at rear, and narrow border around ear-coverts, with breast more prominently rufous; supercilium lemon-yellow behind eye, anteriorly more greenish-yellow (approaching colour of lores), dark greenish eyestripe curving down around rear ear-coverts to lower rear corner, malar stripe usually absent; nape a mixture of yellow and greenish-grey, upperparts more richly coloured than in fresh plumage. Female in fresh plumage is in general more variable than male, with pattern similar, but less prominent and brilliant colours above, and slightly paler yellow below, much broader olive on crown, ear-covert markings, malar stripe and throat marks, olive nape and band around lower neck and shoulder, breaking up on side of breast; in the hand, differs from male in having greyish crown tips usually more extensive, with more and longer prominent dark shaft streak and reduced amount of yellow. Female in worn plumage shows less extensive yellow on head and more streaked crown, also grey-green head side with no yellow, otherwise similar in pattern to male, but in general with rather dull ground colours above and paler yellow below, where greyish-black streaking on breast and flanks more marked, and throat pale yellow; in the hand, crown feathers have the greyish tip usually more extensive, with more and longer prominent dark shaft streak and reduced amount of yellow, compared with male. First winter is rather less distinctive, with less yellow on head, which usually almost wholly brown, lacking obvious supercilium, and with diffuse streaks on crown, and buff-white underparts with only some faint yellow tinge; first-winter male plumage similar to adult female, except for brighter yellow and chestnut tracts and reduced size of marks on head; first-winter female duller than adult in similar plumage, but still lacking olive on crown and nape. Juvenile is variable, but has pattern of more intense streaking on underparts and duller colours than average adult female, with indistinct supercilium, and broader blackish streaks on mantle and scapulars. Race *caliginosa* male is slightly darker, more richly coloured and with more streaks than nominate; *erythrogenys* is paler and less well streaked than male nominate, with hindneck and shoulders greyish (rather than greenish), and with yellow pigments and chestnut on flanks and breast richer. Voice. Song, generally from top of tree, bush or wire, consists usually of a rather constant series of 5–12 similar notes, usually ending in drawn-out descending note of different pitch, e.g. "zi-zi-zi-zi-zi-zi-zi-ziiiiiiii", penultimate note usually a little higher before the descent of lower final note; geographical dialects occur. In analysis of territorial songs of different males four different structures distinguished, with frequency ranges of elements more constant across individuals than were the ranges of the notes, and among the latter the low-frequency element was nearly twice as conserved as the high-frequency element. Call notes characteristic, the commonest a "stif", as well as an array of subtle variations of similar clicking calls, e.g. "pt...pt", also "trp", and a fine "tsii" described as alarm call.
Habitat. Breeds mainly in open woodlands, scrub, heathland, cultivations and similar habitats, also riparian forest and orchards, avoiding dense forest. Most abundant between 600 m and 900 m; in S of range a rather montane species, inhabiting clearings in forest to 2000 m, especially in areas where cereals are cultivated on higher slopes. In Ukraine and Russia extends into steppe oakwood (*Quercus*); at margin of forest tundra and true tundra in N of range in E. In winter mostly in agricultural land, often stubble fields, unharvested cereal fields, pastures, margins of fields (where weed seeds may be found), orchards, edges of forest and on waste ground. Roosts in trees or bushes, sometimes in reeds.
Food and Feeding. Mostly seeds; during breeding season, at least, also invertebrates. Recorded foods include seeds and other parts of spruce (*Picea*), pine (*Pinus*), beech (*Fagus*), grape (*Vitis*), mistletoe (*Viscum*), and several other plant species, such as those of genera *Urtica*, *Rumex*, *Polygonum*, *Chenopodium*, *Stellaria*, *Cerastium*, *Rubus*, *Vicia*, *Trifolium*, *Empetrum*, *Myosotis*, *Coryza*, *Taraxacum*, *Centaurea*, *Sonchus*, *Achillea*, *Helianthus* and *Plantago*, and several grasses (Poaceae), especially cereals. Several studies in UK farmland areas during autumn–winter reveal high consumption of cereal grain (wheat and oats constantly preferred over barley), as well as a few common weed species, taken in proportion to their availability and size. During breeding season, shift towards invertebrates is related to feeding of nestlings. Takes wide array of invertebrates, which include springtails (Collembola), mayflies (Ephemeroptera), grasshoppers and crickets (Orthoptera), cockroaches (Blattodea), earwigs (Dermaptera), bugs (Hemiptera), lacewings (Neuroptera), adult and larval butterflies and moths (Lepidoptera), caddis flies (Trichoptera), flies (Diptera), Hymenoptera, beetles (Coleoptera), spiders (Araneae), woodlice (Isopoda), millipedes (Diplopoda), earthworms (Lumbricidae), and snails (Gastropoda). Forages almost exclusively on ground, but recorded also as clinging from tall herbs, especially during snowfalls. During breeding season, different techniques for catching insects recorded, including brief pursuits of flying insects, also jumping from ground, and even briefly hovering from branches on trees. Outside breeding season, feeds in flocks of variable size, usually of the order of tens of individuals, occasionally hundreds, rarely more (flocks of up to 3000 individuals recorded in Germany); often with mixed-species flocks containing other buntings and finches (Fringillidae). Roosts of variable size, normally of several tens or hundreds of individuals, sometimes up to 1000, usually also with other species such as *E. calandra* and some finches.
Breeding. Normally begins in Apr, later at higher latitudes, with late broods started in Sept; most first broods started May in W & C Europe; normally two broods, sometimes three. Nest built by female, sometimes joined by male on movements to/from site, material gathered from immediate surroundings of (normally within maximum radius of 50 m); composed of dry grass, plant stems, leaves and some moss, lined with rootlets, fine grass and sometimes animal hair, external diameter

11·5–13 cm, internal diameter 5·5–7 cm, depth of cup 4–4·5 cm, placed on or near ground, well hidden among grass or herbage, typically against base of herb, bush or small three, or inside well-protected thorn bush such as *Rubus*. Clutch 3–5 eggs, white, tinged bluish, greyish or purplish, usually some fine faint pale violet or purple spotting, rather variable in colour; incubation usually by female alone, period 12–14 days; chicks brooded entirely by female, male delivers food, nestling period 11–13 days. Breeding success in Britain was 58% of 244 hatched eggs in complete clutches, hatching success increasing from May to later in season; 44% of clutches produced fledged young at a locality in Britain, 52% did so at a German site; nests frequently preyed on by rodents and by corvids including crows (*Corvus*), Eurasian Jay (*Garrulus glandarius*) and Common Magpie (*Pica pica*). Predation accounted for 64% of nest failures; in one UK study examining variation in habitat selection and breeding success, territories found to be associated with hedgerows, vegetated ditches and wide uncultivated grassy margins around fields, avoiding pastures and silage leys, breeding starting slightly earlier on organic farms than on intensively managed ones, but with no differences in breeding success; another study found relationship between mixed farming and improvement of breeding success (abandonment of mixed-farming practice adversely affected success).

Movements. Sedentary and partially migratory. Only extreme N part of range completely vacated during winter. In W part of range autumn movements Sept–Nov, arriving regularly in winter in areas of coastal and inland Spain (where absent as a breeding species), as well as in coastal areas of Italy (where also not breeding), and similar pattern in parts of Balkans, most of Black Sea region and Mediterranean in Turkey, S to N Israel; in severe winters extends S to S Spain, N Africa, Cyprus and United Arab Emirates. E populations dispersive and migratory, wintering S mainly to Transcaucasia, N Iran, S Kazakhstan and N Mongolia, minority resident in W Siberia.

Status and Conservation. Not globally threatened. Locally common to very common; scarce in some areas. Introduced in New Zealand between 1862 and early 1870s, and now widespread and common throughout the islands; has also reached other islands in that region, e.g. Kermadecs, Lord Howe I. In Europe (including European Russia), breeding population estimated to number 18,000,000–31,000,000 breeding pairs, and considered stable during 1970–1990, equating to c. 54,000,000–93,000,000 individuals. Europe forms 50–74% of global range, and a very preliminary estimate of global population is 73,000,000–186,000,000 individuals; further estimates based on more reliable data, especially for Russia, are needed. Although declines recorded in Fennoscandia, Latvia and W Europe (Ireland, UK, Belgium, Netherlands), Austria and Italy during 1990–2000, most C & E European populations (including sizeable ones in Germany, Czech Republic, Poland and Ukraine) were stable; Russian trend not known. Changing land use and farming practices affect populations densities locally.

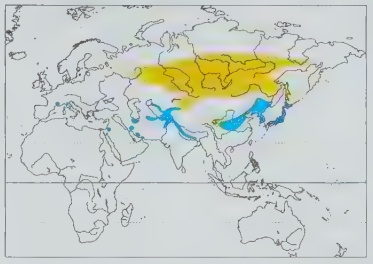
11. Pine Bunting

Emberiza leucocephalos

French: Bruant à calotte blanche **German**: Fichtenammer **Spanish**: Escribano Cabeciblanco

Taxonomy. *Emberiza leucocephalos* S. G. Gmelin, 1771, Astrakhan, Russia.



Most closely related to, and perhaps forming a superspecies with, *E. citrinella*; sometimes considered conspecific, but the two differ clearly in plumage, as well as in behaviour and osteology, supporting treatment as separate species. Closest species to this pair are *E. stewarti* and *E. cirlus*. Present species and *E. citrinella* hybridize extensively in W & C Siberia (across c. 3000 km in taiga and forest-steppe zone from R Ural E to L Baikal), and intensity of interbreeding is increasing, since each species is expanding its breeding range across/towards that of the other; this type of interbreeding has been described as intermediate between occasional hybridization (not influencing gene pools of parent species) and introgressive hybridization (resulting sometimes in local fusion of species). An independent recent analysis of phylogeny supports recognition of two independent species, although cytochrome *b* sequences are very similar, resulting in a strong indication that they are sister-species; sharing of haplotypes even in very distant locations seems to be result of introgression of mitochondrial DNA. An independent alternative study also argues that both species are older than their closest relatives and that mtDNA has recently introgressed between them, most likely as a result of selective sweep. Proposed races of present species *stachanowi* (described from Naryn, in Tien Shan of C Kyrgyzstan) and *karpovi* (from Chita, in Transbaikalia, and Blagoveshchensk, in SE Russian Amurland) are synonymized with nominate. Two subspecies recognized.

Subspecies and Distribution.

E. l. leucocephalos S. G. Gmelin, 1771 – E European Russia from C & S Ural region (Sverdlovsk district and Chelyabinsk) E across Siberia (N to c. 62° in W and 67° in E) to Russian Far East (upper R Kolyma and mountains N of Sea of Okhotsk), S to N Kazakhstan, C & E Tien Shan, NW & NE China, N Mongolia, and lower R Amur and Sakhalin I; bulk of population winters from Afghanistan and N Pakistan E to Nepal, N China, N Mongolia and Japan, and S to S Turkmenistan, N & SW Iran and N Israel (also tiny numbers in NE Italy and SE France).

E. l. fronto Stresemann, 1930 – NE Qinghai (from E border of Zaidam Depression) E to S Gansu, in NC China.

Descriptive notes. 16–17·5 cm; 18·5–37 g. Rather large bunting, similar in size to *E. citrinella*, but slightly larger, with tail 5–10% longer. Male nominate race in worn plumage (Mar–Jul) has distinctive head pattern, with black on forehead and continuing as two black lateral crownstripes bordering white crown to rear nape (sometimes a hint of grey below lateral crownstripe), broad deep brick-red supercilium, white ear-coverts and cheek with often incomplete black borders, deep brick-red lores, chin and throat, brick-red colour extending rearwards as band beneath black ear-covert border; eyering of same colour as supercilium; nape grey-brown with faint darker brown streaks, mantle and back pale reddish-brown with darker brown stripes (no indication of green tones), shoulder shows reddish-brown tones, rump reddish-chestnut and uppertail-coverts slightly darker; scapulars of same colour as mantle, but with

broad bright reddish-chestnut fringe and each feather with conspicuous dark brown streak on shaft; edges of primaries and secondaries white to pinkish-buff (no yellow), pale tips of greater upperwing-coverts forming indistinct whitish wingbar, median upperwing-coverts rufous-buff with whitish fringes (forming additional thin bar), outer rectrices with white shafts; distinct white half-collar between throat and breast (some individuals have fairly distinct greyish additional collar below this), breast and flanks brick-red (paler than same tones on head), flanks with much white admixed, rest of underparts whitish without any yellow tones; iris dark brown; bill blackish-grey on upper mandible, lower mandible horn to grey-horn, often brighter along cutting edge; legs pale and variable, from fleshy-orange to fleshy-brown. Male in fresh plumage (Aug–Nov) has pattern reminiscent of male *E. citrinella*, but with yellow replaced by white; dark streaks on crown created by grey-brown fringes on head feathers (lost when plumage worn), present also on ear-coverts, which have fringes greyish-brown and whitish; streaks on crown slightly more distinct than those of *E. citrinella*. Female in worn plumage is similar to *E. citrinella*, but lacking yellow tones: central crownstripe rather variable individually, but on average is limited to rear crown; whitish spot on nape. Female in fresh plumage (non-breeding) is very similar to worn plumage (in spring–summer), but generally paler, and with rufous tones less marked on supercilium, throat and underparts. First-winter male is similar to fresh-plumaged adult, but general tones darker and brick-reddish tones on throat and supercilium not so well marked; pattern of breast and flanks not so well marked as on adult. First-winter female is like fresh-plumaged adult, but duller. Juvenile is very similar to first-winter female, but in general with even duller tones and more tinged buffy-brown, especially on upperparts. Race *fronto* male differs from nominate in having broader black bands on head, especially on forehead, chestnut tones on average darker, also slightly longer wing. Voice. Calls and song very similar structurally to those of *E. citrinella*, songs being only a little shorter and slower, with fewer, more evenly spaced notes. Detailed analysis in zone of sympatry reveals that song of present species differs from those of *E. citrinella* in having smaller number of notes, lower rate of repetition, and longer pauses between the series of notes; main difference is in frequency of initial notes, either evenly spaced or accelerating, these including a normal song, "zi-zi-zi-zi-zi-zi-ziiiiiiii", in which (according to sonagrams) each "zi" element is composed of two parts, one higher and one louder, the latter more evident than in *E. citrinella*, making song in some ways softer. Also described is a slight difference in pitch of notes, those of present species being higher. Calls "stif" and various clicks, more or less identical to those of *E. citrinella*.

Habitat. Prefers edges of forests and clearings in S taiga, also areas devoid of trees following logging or fires in denser parts of forest. In Kazakhstan breeds in coniferous and mixed forests with shrubs, to 2000 m. Present also in small patches of trees and forest "islands" in the steppe and on outskirts of settlements. During migration and winter found in open landscape with scrub and trees, in forest belts, gardens and tall weedy thickets, normally with arable fields, orchards, gardens or waste ground, often near water and swampy pastures. Tiny population wintering in Italy prefers well-preserved, flat or gently undulating coastal dunes; in Israel, present in badlands and garrigue on mountain slopes and in open hilly areas; in SE France (Camargue) recorded in old sand dunes recolonized by vegetation, with good shrub and tree cover, which occur as isolated islands in cultivated areas.

Food and Feeding. Diet during breeding season mainly invertebrates, such as grasshoppers (Orthoptera), bugs (Hemiptera), beetles (Coleoptera), caterpillars (Lepidoptera), flies (Diptera), spiders (Araneae) and snails (Gastropoda). Nestling diet also invertebrates, including similar array of species to that taken by adults, as well as some seeds. Outside breeding season diet based mainly on seeds of several cereals, e.g. wheat, oats, barley, rye and rice, as well as those of some herbs and grasses. Forages mainly on ground. During migration and winter forages in flocks of variable size, often small groups, but up to 150 individuals in Kyrgyzstan and several hundreds in Mongolia, usually mixed with other seed-eating species such as other buntings and finches (Fringillidae).

Breeding. Season late Apr to end of Jul, usually most pairs starting during May; normally two broods. Nest built by female, a tightly woven cup of grass, rootlets and stalks, lined with soft grass and sometimes hair, placed normally in small depression on ground sheltered by grasses, bush or fallen vegetation. Clutch 4–5 eggs, rarely 6, pale whitish-blue or whitish-green, marked with small dark dots, streaks and a few fine lines; incubation entirely by female, period 13 days; chicks fed by both sexes, nestling period 9 days, young fully fledged 1–3 days later.

Movements. Chinese race *fronto* resident. Nominate race migratory. Autumn migration starts in Aug or Sept, later, in Sept/early Oct, at Chokpak Pass, in W Tien Shan (Kazakhstan), usually in flocks of several tens, and finishing during Nov; regular passage recorded at some places in Japan, such as migration watchpoint of Hegura-jima (off NC Honshu), during Oct. Arrival on wintering grounds in Afghanistan and India during Nov. In W Europe, tiny population wintering in Italy present between mid-Oct and mid-Mar. Return migration at Chokpak recorded from mid-Feb to early May, in flocks of 30–40 birds, finishing during mid-Apr; in N Kazakhstan a little later, from end Mar to early Apr, finishing end Apr. Spring migration seems to be rather quick, since individuals already on breeding grounds in Yakutia, in NE Russia, from second half of Apr, when none present on wintering grounds. Vagrants recorded widely W to NW Europe, S to N Africa and Saudi Arabia, and in Korea and Alaska; small numbers now regular in winter in SE France (Camargue).

Status and Conservation. Not globally threatened. Locally common. No realistic estimates of global population, since bulk of this breeding in Siberia, where surveys needed; European breeding population estimated at 50–100 breeding pairs, but this accounts for less than 5% of global range. Despite lack of detailed information, numbers thought to be stable. Process of interbreeding with *E. citrinella* in areas of contact is producing a zone of local fusion of species in two areas, i.e. SE of W Siberia and adjoining regions of NW Altai; this has led to a sharp decline in numbers of present species in former area (in vicinity of Novosibirsk). This process is still evolving, and long-term outcome requires further study. Wintering presence in Italy discovered in 1994–1995, in Tuscany (L Orbetello); in following winter further individuals discovered elsewhere in W Italy, including flock of 45–50 individuals near mouth of R Serchio in Pisa, and subsequent overwintering recorded also in NE Italy.

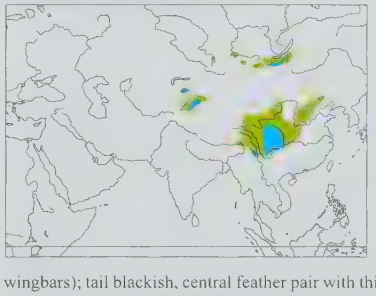
12. Rock Bunting

Emberiza cia

French: Bruant fou **German**: Zippammer **Spanish**: Escribano Montesino
Other common names: Western Rock Bunting, European/Eurasian Rock Bunting, Meadow Bunting(!)

Taxonomy. *Emberiza cia* Linnaeus, 1766, southern Europe = lower Austria.
Forms a superspecies, and previously treated as conspecific, with *E. godlewskii*. Recent phylogenetic analysis indicated that, according to cytochrome *b* tree, interrelationships among present species, *E. godlewskii* and *E. cioides* are unresolved. Similarities in plumage to *E. capensis*, *E. striolata* and *E. tahapisi* seem to be result of parallel evolution, rather than close phylogenetic relationship. Geographical variation mainly clinal, races grading into each other; birds from N Europe tend to be darker than those from S Europe and C Asia, but differences between races generally slight. Other proposed races are *callensis* (from Bom Jesus, Braga, in N Portugal), *africana* (from Spain and Morocco E to Tunisia) and *mokrzechyi* (from extreme W Caucasus), all synonymized with nominate; and *prageri* (from Crimea and Caucasus), *serebrowskii* (from Altai and Tarbagatay) and *lasdini* (from Pamirs), all synonymized with *par*. Four subspecies recognized.
Subspecies and Distribution.
E. c. cia Linnaeus, 1766 – C & S Europe E to Turkey and Levant, and N Africa E to Tunisia.
E. c. par E. J. O. Hartert, 1904 – Crimea and Caucasus and E Turkey E to Iran, and C Asia E to W Mongolian Altai.
E. c. stracheyi F. Moore, 1856 – NW Himalayas from extreme SW China (SW Xizang), Baltistan and Kashmir E to N India (Kumaon) and W Nepal.
E. c. flemingorum J. Martens, 1972 – W & C Nepal.



Descriptive notes. 15–16·5 cm; 17–29 g. Fairly large bunting, with proportionately short wing and long tail. Male nominate race in fresh plumage has pale ash-greyish head, throat and breast, contrasting dark lateral crownstripe, eyestripe and moustachial stripe, latter extended posteriorly to meet rear eyestripe at nape side; upperparts rich chestnut with broad black streaks, rump and uppertail-coverts unstreaked reddish-brown; upperwing mostly blackish, flight-feathers with narrow pale outer edges, tertials with pale rufous outer edges and narrower inner edges, median coverts tipped whitish (forming wingbar), greater coverts tipped buffish-white (second, less obvious wingbar); tail blackish, central pair with thin rufous edges, outer pairs with white on one or both webs, amount of white increasing outwards, outermost rectrix white on outer half of inner web and on most of outer web; underparts below breast rusty brown; tinges of yellowish-brown in this plumage disappear with wear, producing more contrasted pattern in spring; iris dark brown; bill greyish, darker above and light lead-grey below; legs bright orange-flesh or reddish. Female is similar to male, normally somewhat duller, with less extensive grey on breast and with more diffuse head pattern, but sometimes not reliably separable. Juvenile has buff to rufous-buff head streaked dark, dark eyestripe, brownish ear-coverts bordered dark below, upperparts buff to reddish-buff with prominent dark brown streaking, rump somewhat more rufous and also streaked, upperwing-coverts tipped buffish, tertials black with light rufous edgings, underparts buffish, breast streaked dark, flanks less boldly streaked; bare parts much as for adult. First-winter is similar to adult female. Races differ mainly in plumage darkness, but variation largely clinal, becoming paler and greyer from N to S and from W to E: *par* is very similar to nominate, but paler and larger; *stracheyi* is darker and more richly coloured, with tips of median and greater upperwing-coverts rufous-buff (instead of whitish), in size intermediate between previous and nominate; *flemingorum* is smaller and paler than last, with both wingbars buffish. Voice. Song, normally from rock or top of tree, a melodic verse with sudden scale changes, and sometimes as a short high-pitched phrase with last note rising and repeated; reminiscent of song of Dunnock (*Prunella modularis*) and, to lesser extent, a weaker version (though more musical) of *E. schoeniclus*, also in some ways even of song of Eurasian Wren (*Troglodytes troglodytes*) and in some instances part of the phrases normally sung by Common Chaffinch (*Fringilla coelebs*). Calls normally a weak and sharp "tzi" and variants, sometimes a little longer; also "trrr" when disturbed.
Habitat. Sunny places on rocky slopes in hills and high mountains, ravines, and in clearings in conifer forests and, less usually, deciduous forests, as well as in areas with bushes and young trees, cultivated terraces, and vineyards. In general prefers areas where bare soils and rocky areas alternate with sparse vegetation, S-facing when on slopes, and with varied relief and availability of exposed perches. According to one study in S Spain, habitat selection during breeding is determined by need for protection against predators, selecting to place nests under patches of low vegetation (to detect approach of predator), but close to taller vegetation (to provide cover when escaping); in study in Slovakia, for breeding chose patches having relatively lower bush cover, relatively higher rock cover, and higher complexity of horizontal surface. In winter found also in lowland sites, where more common in cultivated areas and wastelands. To c. 4000 m in Asia.
Food and Feeding. Outside breeding season feeds mainly on seeds of herbs and other plants, and during breeding period mostly on invertebrates. Among invertebrates recorded as food are mayflies (Ephemeroptera), grasshoppers (Orthoptera), bugs (Hemiptera), flies (Diptera), adult and larval Lepidoptera, ants (Formicidae), adult and larval beetles (Coleoptera), spiders (Araneae), earthworms (Lumbricidae), snails (Pulmonata). Plant seeds include those of knotgrass (*Polygonum*), chickweed (*Stellaria*), fleabane (*Conyza*), woodrush (*Luzula*), several kind of grasses (Poaceae) and mosses. Nestling diet mostly invertebrates, when older also seeds. Forages mainly on ground, in rocky areas or along scrubby vegetation, also in low herbs and grass in fields and similar places. Recorded also as hanging in herbs to reach seeds at tips of plants, as well as taking insects by flight in manner of flycatchers (Muscicapidae). In post-breeding period, gathers in small loose flocks at or near breeding site. In winter found singly and in parties of up to ten or so individuals, sometimes joining other seed-eating species; during cold-weather movements sometimes in flocks of up to 15–30 individuals, exceptionally 40–70.
Breeding. Season from late Mar or Apr to Jul–Aug, occasionally to mid-Sept, peak of egg-laying in most of range during May; sometimes two broods, regularly so if first one successful, exceptionally three broods. Nest built by female, taking usually 6–8 days, composed of dry herbs and mosses, together with fine grasses and hair, normally placed in sunny site on ground, protected by vegetation, or at base of rock, and exposed to S, but sometimes in shady place, access normally by rocky surface more or less devoid of vegetation; rarely, in crevice in wall or in tree. Clutch 3–6 eggs, pale greyish to purplish-white, heavily and intricately scrawled with long and meandering dark black streaks; incubation by female, period 13–15 days; chicks fed by both parents, nestling period 9–13 days; young leave nest before able to fly, becoming independent three weeks later. In study in Germany, only 47% of nests produced fledged young; losses due mainly to predation by mustelids such as stone marten (*Martes foina*), least weasel (*Mustela nivalis*) and ermine (*Mustela erminea*), also by red fox (*Vulpes vulpes*), several corvids including Eurasian Jay (*Garrulus glandarius*), Common Raven (*Corvus corax*) and Carrion Crow (*Corvus corone*), and smooth snake (*Coronella austriaca*).
Movements. N populations partly migratory, some moving short to medium distance S in cold winters. In S of range mostly resident, performing altitudinal movements, or probably only movements of limited distance. Present in coastal areas of Mediterranean where absent during breeding period, but unknown whether this involves local altitudinal migrants or is due to arrivals of individuals from N areas. Recorded as winter visitor in Cyprus and Iraq. Vagrants have reached Great Britain, Netherlands, Denmark and Sweden.
Status and Conservation. Not globally threatened. Locally common; rather sparsely distributed. European breeding population estimated at c. 1,300,000 pairs. Large decline recorded during 1970–1990; long-term monitoring at locality in Baden-Württemberg, in S Germany, between 1950s and 1970s and in 1988 revealed decline of at least 35–45%. During 1990–2000 considered stable overall in European range; present population probably below previous levels. Abandonment of traditional farming practices, the intensification of agriculture (and spread of monocultures) and extension of urban zones adversely affect the whole population, since these are causes of habitat loss; reforestation of many areas in Europe is also having negative effect. On the other hand, factors such as fires in Mediterranean area, which could help to produce patches of new habitat in the form of open areas, could benefit this species. Little information on status in E of range; thought to be relatively stable and locally common.
Bibliography. 13. Godlewski's Bunting

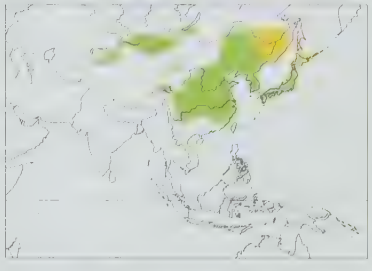
Emberiza godlewskii

French: Bruant de Godlewski **German**: Felsenammer **Spanish**: Escribano de Godlewski
Other common names: Eastern Rock Bunting

Taxonomy. *Emberiza godlewskii* Taczanowski, 1874, southern Dauria and Kultuk, Mongolia [= southern Lake Baikal, Russia].
Forms a superspecies, and previously treated as conspecific, with *E. cia*. Recent phylogenetic analysis indicated that, according to cytochrome *b* tree, interrelationships among present species, *E. cia* and *E. cioides* are unresolved. Similarities in plumage to *E. capensis*, *E. striolata* and *E. tahapisi* seem to be result of parallel evolution, rather than close phylogenetic relationship. Proposed races *nanshanica*, described from C China (R Churmyk, basin of upper Hwang-he, in E Qinghai), and *gobica*, from WC Mongolia (S slope of Khangai Mts), synonymized with nominate, and, also in C China, *styani* (from Songpan, in W Sichuan) and *bangsi* (from Pashui, in Shaanxi) are treated as synonyms of *omissa*. Five subspecies recognized.
Subspecies and Distribution.
E. g. decolorata Sushkin, 1925 – NW China (foothills of S & E Tien Shan, in W Xinjiang); in winter also in valley of upper Syr Darya.
E. g. godlewskii Taczanowski, 1874 – Russian Altai E through Sayans to S end of L Baikal and W Transbaikalia, Mongolia, and N China (S to N & E Qinghai and Gansu).
E. g. khamensis Sushkin, 1925 – SC China from S Qinghai S to S & SE Tibetan Plateau (to Lhasa and Gyantse regions) and W Sichuan (to c. 29° N).
E. g. omissa Rothschild, 1921 – E China from S Heilongjiang S to N & E Sichuan.
E. g. yunnanensis Sharpe, 1902 – S China in extreme SE Tibetan Plateau and N Yunnan E to C Sichuan; also NE Myanmar in winter.

Descriptive notes. 17 cm; 14–23 g. A fairly large bunting, superficially similar to *E. cia*. Male nominate race has grey head, throat and breast, broad chestnut lateral crownstripe and posterior eyestripe, black loral stripe and moustachial stripe, and chestnut border of rear and lower ear-coverts; upperparts pale rufous with broad black streaks, rump and uppertail-coverts unstreaked reddish-brown, bright chestnut scapulars contrasting with mantle; upperwing blackish, flight-feathers with narrow pale edges, tertials with pale rufous outer edges and narrower inner edges, median and greater coverts tipped white (forming two wingbars); tail blackish, central feather pair with thin rufous edges, outer pairs with white on one or both webs, amount of white increasing outwards; underparts below breast pale ochraceous; when fresh (after moult), plumage duller-looking and slightly paler; iris dark brown; upper mandible blackish, lower mandible bluish-grey with blackish tip; legs pinkish-brown. Differs from *E. cia* mainly in less striking head pattern, paler upperparts with brighter chestnut scapulars, more marked wingbars, paler underparts. Female is very like male, perhaps slightly duller and with slightly darker crownstripes. Juvenile has buff to rufous-buff head streaked dark, dark eyestripe, brownish

On following pages: 14. Meadow Bunting (*Emberiza cioides*); 15. White-capped Bunting (*Emberiza stewarti*); 16. Jankowski's Bunting (*Emberiza jankowskii*); 17. Grey-necked Bunting (*Emberiza buchanani*); 18. Cinereous Bunting (*Emberiza cineracea*); 19. Ortolan Bunting (*Emberiza hortulana*); 20. Cretzschmar's Bunting (*Emberiza caesia*); 21. Cirl Bunting (*Emberiza cirlus*).



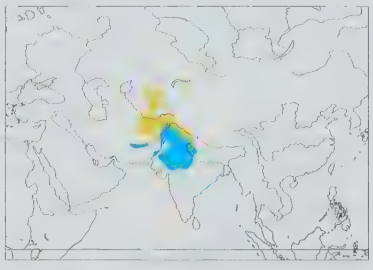
ear-coverts bordered dark below, upperparts buffish with prominent dark brown streaking, somewhat more rufous rump also streaked, upperwing-coverts tipped buffish, underparts buffish, breast with dark streaking, flanks less boldly streaked; bare parts much as for adult. Race *decolorata* is palest, with mantle, edges of greater upperwing-coverts and underparts paler sandy rufous, female may be even more pale and nondescript; *khamensis* is darker than nominate and more heavily streaked on mantle; *omissa* is rather more richly coloured than previous; *yunnanensis* is darkest, with the most saturated plumage tones. Voice. Song, usually from top of rock or tree, quite variable, apparently begins with much higher-pitched "tziit" notes than song of *E. cia*, and consists of a series of twittering notes, less varied and musical than those of latter, repeated several times. Calls include "tzii", similar to but slightly higher pitched than that of *E. cia*, also a harder "pett pett".
Habitat. Bushy and rocky slopes in mountains and hills, also in ravines, often near forest; avoids higher mountains. Common also in montane steppe zones in C Siberia, as well as on rocky meadow-steppes, where present also during winter; less numerous in larch (*Larix*) forests on slopes and in valley pine (*Pinus*) forests in rocky regions. Outside breeding season found in lowland areas, where it visits farmland and cultivated fields.
Food and Feeding. Diet outside breeding season consists mostly of seeds, especially of grasses (Poaceae); during breeding period a variety of invertebrates. Forages mostly on ground. In non-breeding season usually in small flocks, sometimes up to 35 individuals, and sometimes mixed with *E. spodocephala* and rosefinches (*Carpodacus*).
Breeding. In N of range most start to breed from mid-May, a proportion not before end Jun. Nest cup-shaped, with loose structure made from withered grasses and plant stems, lined with fine rootlets and hair, placed on ground under overhanging rock, or sheltered by stones. Clutch 3–5 eggs, very similar to those of *E. cia*; incubation c. 13–14 days; nestling period 10–14 days.
Movements. Resident, with local dispersive movements. Apparently makes altitudinal movements, which could be reason for presence in non-breeding season in areas such as N Myanmar.
Status and Conservation. Not globally threatened. Locally common to fairly common. Global population size not quantified, but numbers thought to be stable in absence of evidence of declines or reported threats. Reaches densities of 40 birds/km² in areas of montane steppe, being the most numerous species in R Bolshiye Ury basin, in Altai region of Russia; in lower densities of 2 birds/km² in larch forests on slopes and in valley pine forests in rocky regions.
Bibliography. Alström *et al.* (2008), Armani (1985), Byers, Olsson & Curson (1995), Dementiev *et al.* (1954, 1970), Dornberger (1981), Dorzhiev & Jumov (1991a, 1991b), Flint *et al.* (1984), Gavrilov & Gavrilov (2005), Harrison (1934), Hesse (1913), Johansen (1905, 1944), Mauersberger (1972), Mauersberger & Portenko (1971), Rasmussen & Anderton (2005a, 2005b), Sushkin (1925), Tsybulin (1988).

14. **Meadow Bunting**

Emberiza cioides

French: Bruant à longue queue **German**: Wiesenammer **Spanish**: Escribano de Brandt
Other common names: Siberian Meadow Bunting, Long-tailed/Red-eared Bunting; Japanese Meadow Bunting (*ciopsis*)

Taxonomy. *Emberiza cioides* J. F. Brandt, 1843, Siberia.
Japanese race *ciopsis* differs quite strongly from others both in head colour and in vocalizations, and could be worthy of species status; further study needed. Geographical variation somewhat clinal, involving size and colour saturation: other proposed races include *shiretokoensis* (described from E Hokkaido, in N Japan), synonymized with *ciopsis*; in SE Russia, *ussuriensis* (from Ussuri) and *vagans* (from mouth of Sidemi, in Amur Bay and mid-Ussuri), both subsumed in *weigoldi*; and, in China, *tangutorum* (from near Xining, in W Qinghai), treated as synonym of nominate. Five subspecies recognized.
Subspecies and Distribution.
E. c. tarbagataica Sushkin, 1925 – NW China from SW Altai S to C & E Tien Shan (in N Xinjiang).
E. c. cioides J. F. Brandt, 1843 – SC Siberia from E Altai E to Mongolia and adjacent Transbaikalia (Buryatia) in EC Russia.
E. c. weigoldi Jacobi, 1923 – E of Transbaikalia in SE Russia (Amurland and Ussuriland), S to NE China (S to Hebei) and N Korea.
E. c. castaneiceps F. Moore, 1856 – E China (S of Hebei) and S Korea.
E. c. ciopsis Bonaparte, 1850 – S Sakhalin I and Kuril Is S through Japanese islands to Yakushima (S of Kyushu).



Descriptive notes. 17 cm; 17–26 g. Relatively large and long-tailed bunting. Male nominate race breeding (plumage worn) has crown chestnut, relatively broad white supercilium, chestnut ear-coverts, contrasting white moustachial stripe and black submoustachial stripe; nape pinkish-buff, side of neck grey, upperparts rufous-brown, streaked dark brown, rump and uppertail-coverts unstreaked chestnut; wing feathers brownish-black, edged reddish or dull brown, median and greater upperwing-coverts narrowly tipped white; tail dark, with extensive white mostly on outermost pair; throat off-white, bordered below by broad chestnut breastband; side of breast and flanks rufous, paling to pinkish-buff on belly and off-white on undertail-coverts; iris brown; upper mandible and bill tip blackish, lower mandible grey; legs greyish-pink. Differs from similar *E. jankowskii* in having ear-coverts chestnut (rather than grey), less obvious wingbars, unmarked rufous underparts without dark belly patch, and less bold black streaking on mantle. Male non-breeding (plumage fresh) has colours dulled by buffy-grey feather tips, often completely obscuring chestnut breastband, and buffy edges of crown feathers giving impression of narrow central crownstripe; streaking on mantle less well defined owing to pale feather edges. Female resembles male in plumage colour, but somewhat duller, usually with weaker facial pattern, but many are superficially very similar. Juvenile resembles female, but paler buffy brown overall, with head very finely streaked, and breast speckled, rather than streaked; extremely similar to juveniles of *E. godlewskii* and *E. cia*. Race *tarbagataica* is palest, being sandy brown above, streaked darker on mantle, only a little rufous on rump, and with narrow breastband; *weigoldi* is brighter and more chestnut overall and a little smaller than nominate; *castaneiceps* is smallest and darkest race, only sparsely streaked above and with brownish lower underparts; *ciopsis* is distinctive, has slimmer bill, blackish ear-coverts, less contrast between breastband and lower underparts, and some have dusky blotches on breast. Voice. Song, from top of small bush or tall tree, a short, simple phrase very similar to that of *E. godlewskii*, has been transcribed as "chi-hu chee-tsweet-tsweet-tuee"; song of race *ciopsis* is rather different, having a twittering rhythm, can be transcribed as "ziu-chuhu tsitsirri tsetziz". Typical call a short, thin, repeated "zit zit zit".
Habitat. Found in all manner of lightly wooded rolling hills and mountain foothills; rocky areas of steppe and forest-steppe, also *Caragana* shelterbelts, and sometimes open larch (*Larix*) and pine (*Pinus*) forest on hill slopes; also found in shrub thickets. In Japan, breeds at forest edge and in cultivated fields with thickets. Up to 1700 m. Visits areas around human habitations.
Food and Feeding. Diet chiefly grass and weed seeds, augmented by invertebrates during summer. Feeds mostly on ground, hopping with hunched posture. In winter forages in small to medium-sized flocks of c. 30–40 individuals, exceptionally several hundred individuals; mixes freely with finches (Fringillidae) and other buntings, especially at favoured drinking locations, which it visits first thing in morning and again in late afternoon.
Breeding. Season Apr–Aug; two and often three broods. Monogamous. Nest built by female alone, a cup of rootlets and grasses, lined with finer materials such as horsehair, placed on or just above ground, usually concealed by small bush or clump of grass. Clutch 3–6 eggs, mean 4, whitish or pale grey, marked with patches, fine lines and scribbles, incubation period 11 days, fledging after a further 11 days.
Movements. Mostly sedentary or, at most, a short-distance migrant. Remains close to breeding areas in winter, some descending to valley bottoms and gathering into small flocks; more severe weather conditions result in population shifts, but unlikely that any move far from native range. In W Mongolia, present at foot of Mongolian Altai from late Sept to early Apr, with clear maximum in Oct. In Japan a breeding summer visitor to N island of Hokkaido and to nearby Sakhalin I, where arrives in Apr and leaves in Oct; race *castaneiceps* is rare visitor to Japan. Vagrants reported on some S Japanese islands and on Taiwan.
Status and Conservation. Not globally threatened. Common locally over most of its breeding range; little evidence of any marked decreases in recent decades. Densities of up to 80 birds/km² reported from parts of China; likewise, up to 80 birds/km² in *Caragana* shelterbelts with scattered trees, in C Siberian forest-steppe. Records in but in view of this species' generally sedentary nature, all European records almost certainly involve escaped cagebirds.

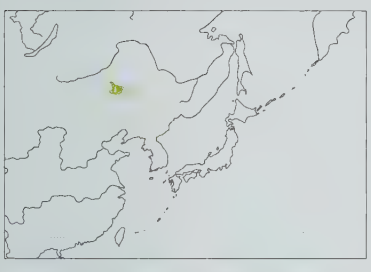
15. **White-capped Bunting**

Emberiza stewarti

French: Bruant de Stewart **German**: Silberkopfammer **Spanish**: Escribano de Stewart
Other common names: Chestnut-breasted/Stewart's Bunting

Taxonomy. *Euspiza stewarti* Blyth, 1854, Landour and Dehra Dun, Uttarakhand, India.
Monotypic.
Distribution. Breeds in mountains from S Kazakhstan (Karatau Range), S Uzbekistan, Tajikistan and W, N & S Kyrgyzstan S to extreme SE Turkmenistan (Kugitang Range), Afghanistan, W & N Pakistan, Kashmir and N India (NW Himachal Pradesh); winter range includes S Afghanistan and the N Punjab of Pakistan, but most move farther S into N Indian states (S to Gujarat, W Uttar Pradesh, Madhya Pradesh and NE Maharashtra).



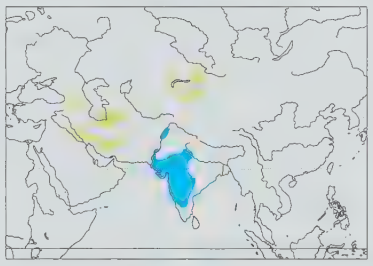
Descriptive notes. 15 cm; 13–21 g. Distinctive bunting with comparatively small bill. Male breeding (worn plumage) has crown and nape, side of head and upper breast light buffy grey, becoming whitish with wear and contrasting with blackish bib extending from throat to submoustachial area and back beneath ear-coverts, and prominent blackish eyestripe; upperparts chestnut, upperwing-coverts brown with paler edgings, tail dark with extensive white in outermost two feather pairs; sides (and narrowly centre) of breast and flanks chestnut, lower underparts off-white, washed pinkish-buff; iris dark brown; bill dark grey; legs greyish-pink. Male non-breeding (fresh plumage) is duller, buff-grey feather tips making black of throat and eyestripe sullied dark brown, and grey of head and breast washed sandy; upperparts duller and browner, with some streaking on mantle. Female has rufous rump, in contrast to overall dull brown and narrowly streaked remainder of plumage; head pattern relatively plain, with slightly darker border of ear-coverts, highlighted by pale spot in lower rear corner; has more white in outermost two pairs of tail feathers than most buntings; some, perhaps older, females show indications of male-like plumage, such as dusky throat or chestnut patches at sides of breast, or chestnut scapulars, and in extreme cases these can be very difficult to age or sex. Juvenile resembles female, but paler buffy brown overall, with head very finely streaked and breast speckled, rather than streaked. Voice. Song, from top of small bush or crag, usually a simple phrase, rather variable, can be a buzzy, metallic rattle finishing with single high-pitched note, or can recall that of *E. citrinella* or *E. leucocephalos*, or even *E. hortulana*, but is slower in delivery and lacks protracted rising terminal note ("cheese"). Calls include high-pitched "tit" and squeaky, staccato "tchirit".
Habitat. Favours rocky gulleys in dry, lightly wooded hills and mountains; associated especially with juniper (*Juniperus*) scrub and stands of chilgoza pine (*Pinus gerardiana*) between 1200 m and 2500 m, but reported as high as 3600 m. Where range overlaps with that of *E. cia*, latter replaces present species at higher elevations. In winter descends to dry foothills, scrub-jungle, poor agricultural land and edges of plains with scattered bushes.
Food and Feeding. Feeds chiefly on grass seeds, augmented by berries in autumn and winter. Young fed with variety of invertebrates, mostly insects and spiders (Araneae). Forages in bushes, as well as on ground, hopping with flat-backed, hunched posture. In winter mixes freely with other buntings and finches (Fringillidae), especially at favoured drinking locations, which it visits first thing in morning and again in late afternoon. In heat of day takes shelter in bushes, sitting quietly with ruffled "crest" of raised crown feathers.
Breeding. Nest-building begins immediately on arrival on breeding grounds, in Apr, and eggs reported from very end of Apr, but mostly from mid-May to early Jun in S of range (Kashmir) and to early Jun in N; many pairs apparently double-brooded. Probably monogamous. Nest built by female alone, a cup of rootlets and grasses, lined with finer materials, placed on ground, usually concealed by small bush or overhanging rock on steep dry slope. Clutch 3–5 eggs (mean 4), white with blue or grey tinge, mottled purplish-grey and with dark red-brown spots and blotches; incuba-

tion probably by female only, period 11–14 days; young leave nest after 8 or 9 days, but unable to fly until c. 14 days old.
Movements. Migratory. Begins to arrive on breeding grounds in Apr. Post-breeding departure through first half of Aug, with stragglers in Sept and early Oct. Reported abundance on passage through Kashmir E to Simla need confirmation, as this species is unrecorded in Tibetan region to N, suggesting that passage birds enter N Pakistan and disperse E along Himalayan foothills. Vagrant in Nepal and SE Iran; recently recorded in United Arab Emirates.
Status and Conservation. Not globally threatened. Common in appropriate habitat over most of C Asian breeding range. Little evidence of any marked decreases in recent decades. This species' preference for rocky ravines renders it relatively safe from indiscriminate forest clearance.
Bibliography. Ali & Ripley (1974), Armani (1985), Bannon & Richardson (1993), Bates & Lowther (1952), Busuttil & Ayé (2009), Byers, Olsson & Curson (1995), Castell & Castell (2009), Dementiev *et al.* (1954, 1970), Grimmett *et al.* (1998), Gubin (1982), Paludan (1959), Portenko & Stübs (1971b), Rasmussen & Anderton (2005a, 2005b), Roberts (1992), Stuart Baker (1926), Wallschläger (1983).

16. Jankowski's Bunting
Emberiza jankowskii

French: Bruant de Jankowski **German**: Jankowskiammer **Spanish**: Escribano de Jankowski
Other common names: Rufous-backed Bunting

Taxonomy. *Emberiza jankowskii* Taczanowski, 1888, near Sidemi, south Ussuriland, south-east Russian Far East.
Monotypic.
Distribution. Breeds NE China (E Inner Mongolia and adjacent W Jilin).



Descriptive notes. 16 cm; c. 20 g. Relatively small-headed and long-tailed bunting. Male breeding (worn plumage) has rufous crown, contrasting whitish supercilium, black stripe from base of bill to eye; lower ear-coverts very pale grey, bordered by black submoustachial stripe, upper ear-coverts darker grey; upperparts mostly reddish-chestnut, mantle duller and paler brown with broad blackish streaks; two white wingbars formed by tips of greater and median upperwing-coverts; tail with white towards tips of outermost two feather pairs, otherwise rectrices dusky with pale fringes, outer webs becoming light reddish towards base; throat and underparts whitish, washed pale grey on centre of breast and light rufous on side of breast and flanks, with dusky-chestnut patch on central belly; iris dark brown; bill grey, darker tip and paler lower mandible; legs greyish-pink. Male non-breeding (fresh plumage) is duller in colour owing to pale feather tips; dark belly patch obscured or smaller. Female resembles non-breeding male, but often has weak speckles across breast and lacks belly patch. Juvenile is duller and colder brown above, with dusky crown centre and weakly streaked flanks. Voice. Song, from top of small bush, usually a simple phrase, has been transcribed as "chu-chu cha-cha cheee" and has been likened to start of an accentor (*Prunella*) song, but finishing with rising "eeee" (like end of *E. citrinella* or *E. leucocephalos* song); a longer, more varied song sometimes recorded, particularly in Jilin. Calls include single or double "tsit", probably as contact; louder, almost explosive "sstillit" serves as alarm call, as probably does a thin penetrating "hsiu".
Habitat. Open grassy habitats, mainly steppes or low hills dominated by the grasses *Filifolium sibiricum*, *Stipa baicalensis* and *Spodiopogon sibiricus*, interspersed with Siberian apricot (*Armeniaca sibirica*) up to 3 m tall. Former Russian populations favoured low rounded hills with stunted scrubby oaks (*Quercus*) within boggy meadows of coastal plain.
Food and Feeding. Little known. Diet quite varied, adults feeding on fallen grain, weed seeds, grasshoppers (Orthoptera) and larval cicadas (Cicadidae). Young fed primarily with invertebrates, recorded items being grasshoppers, caterpillars, and spiders (Araneae) with their cocoons. Forages chiefly on ground; spends more time on ground than most other buntings. On the whole seems to be remarkably confiding, allowing close approach by humans.
Breeding. Little studied. Season in W Jilin late Apr to late Jul; extinct E populations bred later, commencing mid-May and sometimes not until mid-Jun; possibly double-brooded. In scattered colonies within bushy grassland. Nest built by both sexes, from dry grasses, lined with horsehair, placed on ground among sparse grasses, sometimes at base of small tree. Clutch 4–7 eggs (mean 5·26), off-white with faint brownish marks, some dark brown spots and lines; incubation by female alone, period 11–14 days; chicks fed by both sexes, nestling period 10–13 days. Nests parasitized by Common Cuckoo (*Cuculus canorus*). Breeding success low; main causes of failure include nest predation by snakes, ants (Formicidae), possibly also by European suslik (*Citellus citellus*) and Amur Falcon (*Falco amurensis*), also grazing by livestock and nest-robbing by humans.
Movements. Appears to be resident at most sites where breeding has been recorded, perhaps dispersing over relatively short distances after breeding. Occasional short-distance movements in non-breeding season, and, at least formerly, sporadic presence of wintering individuals or small numbers recorded in a few places in Inner Mongolia, S Heilongjiang, Liaoning, Hebei, Beijing and N Korea. In the past possibly a more regular migrant; Russian breeders were said to migrate to nearby N Korea to overwinter there.
Status and Conservation. ENDANGERED. Very rare and local; has declined drastically, and decline continuing. Status altered from Vulnerable as recently as 2010; rate of decline suggests that Critically Endangered might be appropriate. Currently known to breed at only five sites in NE China (four in Inner Mongolia and one in W Jilin), with maximum known total population c. 100 mature individuals. Range formerly extended into extreme SE Russia (along coastal plain of S Ussuriland) and in adjacent extreme NE Korea, but no recent reports from either country; Chinese range formerly more extensive, covering wider parts of W Jilin and breeding also in E Jilin and S Heilongjiang. In first half of 20th century described as locally common in Heilongjiang, but no longer exists at its former sites in that province, nor at those in Russia and N Korea; extinct in E Jilin. In W Jilin, 350 breeding pairs in 1994 (none in 2005) at Huichin, 100 birds in 2001 but only two in 2008 (now extinct) at Baicheng; at Dagang Forest Farm, population dropped from 60 pairs in 1999 to ten in 2010. In Inner Mongolia, habitat destruction at Tumiji grassland had brought numbers down from c. 50 birds to only seven by 2010; two recently discovered sites in this province held, respectively, 53 individuals (29 males) and 13 individuals (nine males) in 2010. No doubt the specialized habitat requirements of this bunting have contributed significantly to its sudden demise. Dry grasslands have been largely destroyed by cutting for winter animal fodder, and extensive accidental or intentional burning, as well as conversion to agriculture and forestry, have also been blamed as main causes. This species, being a ground-nesting bird, must also be vulnerable to predation and trampling by domestic animals and humans. Another factor could be its semi-colonial nesting habits, with successful breeding dependent on close proximity of other pairs. Although protected both in Russia and in N Korea, it no longer occurs there. In China, some protection is afforded by the Xianghai Nature Reserve, but grassland destruction has occurred even inside reserve areas. Clearly, this is one of Asia's most threatened avian species; its only chance for survival depends on creation of a network of surviving grassland patches and much stricter protection from human activities.
Bibliography. Anon. 17. Grey-necked Bunting
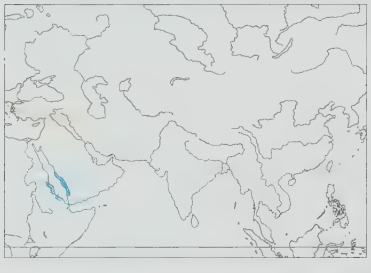
Emberiza buchanani

French: Bruant à cou gris **German**: Steinortolan **Spanish**: Escribano Cabecigrís
Other common names: Grey-hooded Bunting, Buchanan's Bunting

Taxonomy. *Emberiza buchanani* Blyth, 1845, peninsular India.
Forms a species group with *E. cineracea*, *E. hortulana* and *E. caesia*. Proposed race *huttoni* (described from Afghanistan) has features considered to lie within range of variation of nominate, with which it is synonymized. Geographical variation somewhat clinal and variable; species sometimes treated as monotypic. Three subspecies recognized.
Subspecies and Distribution.
E. b. cerrutii De Filippi, 1863 – breeds from SE Turkey, Armenia and Azerbaijan E to W & N Iran and S Turkmenistan; assumed to winter in India.
E. b. neobscura Paynter, 1970 – breeds NE Kazakhstan, Uzbekistan and Kyrgyzstan E to Altai ranges, SW Mongolia and NW China (NW Xinjiang); assumed to winter in India.
E. b. buchanani Blyth, 1845 – breeds from S Uzbekistan and Pamirs of Tajikistan S to N & C Afghanistan and SW Pakistan (Baluchistan); winters over most of W India (S to Hyderabad).

Descriptive notes. 16 cm; 17·2–26 g. Hooded bunting with rather long pale pinkish bill and prominent whitish eyering. Male nominate race breeding (worn plumage) has crown to nape, sides of head and neck, malar stripe and side of breast grey, giving hooded effect; upperparts rufous-tinged grey-brown, finely streaked darker brown, scapulars broadly bordered rufous-cinnamon, upperwing similarly rufous-grey with darker feather centres and paler fringes; tail feathers black, central pair greyish, outermost pair with extensive white over distal portion of inner webs; submoustachial stripe, chin and upper throat whitish, shading to deep cinnamon on breast and remaining underparts, becoming paler on lower underparts; iris dark brown, clearly defined narrow white eyering; bill very pale pink, yellowish or brownish-yellow, somewhat longer and slimmer than that of *E. hortulana*; legs pinkish-orange. Differs from *E. hortulana* mainly in grey (not olive) hood reaching breast sides but not extending over breast, in whitish (not yellowish) chin and submoustachial stripe, also in generally smaller size, relatively longer-tailed appearance in flight, and somewhat longer and slimmer bill. Male non-breeding (fresh autumn plumage) is similar to breeding, but all colours subdued by whitish feather fringes and tips, dulling rufous of underparts, but making white of throat and submoustachial stripe cleaner; upperparts appear paler because of wide sandy-grey feather fringes, tail browner and worn. Female is similar to dullest non-breeding male, but often with some fine streaking on crown and nape, duller pale rufous scapulars and fine streaking across breast. Juvenile plumage is short-lived, similar to female, but nape virtually unstreaked, giving slight contrast with diffusely streaked crown and streaked mantle, scapulars less rufous, and has more extensive rufous and brown streaking on underparts; first-winter similar to adult female, but no rufous visible below. Races differ chiefly in degree of colour saturation in breeding plumage, complicated by extent of wear of pale feather fringes of non-breeding plumage: *cerrutii* is somewhat paler than nominate, more sandy grey (less extensively rufous) above, and less deep cinnamon below; *neobscura* is relatively darker grey above, with bolder blackish streaking on mantle and scapulars, also has more richly coloured underparts. Voice. Song, usually from top of large boulder, a simple phrase of c. 4 rising notes followed by lower-pitched terminal flourish, "tsee-tsee-tsee-tsee-dew-dedew", resembles that of *E. hortulana*; some individual variation, and also recalls high-pitched version of first part of song of *E. citrinella* or *E. leucocephalos*. Calls a soft, short "tsip" or "tsik" and sweeter "seeop" or "choup", all of which may be given in flight; similar to those of *E. hortulana*.
Habitat. Dry, rocky mountainsides, ravines and upland plateaux, with grassy clumps and weedy vegetation; tends to avoid trees, but tolerates broken bushy cover. Breeds chiefly at 900–1400 m, but in some places reaches upper limit of 2400 m, and reported at 3200 m in Afghanistan. In winter found in stony, dry cultivation and *Euphorbia*-covered dry slopes.
Food and Feeding. Wide variety of seeds, and shoots of dry-country plants, including those of bistorts (*Polygonum*), spurge (*Euphorbia*), sea-buckthorn (*Hippophae*) and salt tree (*Halimodendron*), and various grasses. In breeding season young fed almost entirely with invertebrates, especially both larval and adult stages of weevils (Curculionidae) and other beetles (Coleoptera), grasshoppers (Orthoptera), bugs (Hemiptera), ants (Formicidae) and snails (Pulmonata). Forages quietly on ground in pairs and small parties among sparse vegetation; feeds from early morning until 10:00–11:00 hours, before flying to water source, resuming feeding in early evening. Small parties amalgamate in late Jul and Aug prior to migration, but groups rarely exceed 20 individuals, largest recorded flock being of more than 50 (in Pakistan). Flocking not reported on spring passage. On migration in Kazakhstan reported as forming mixed flocks with *E. hortulana*, and in N Pakistan mixed with *E. cia* and *E. stewarti*.
Breeding. Males arrive at breeding sites a few days ahead of females. Eggs reported from late Apr to Jul in Iran, early May in S Turkmenistan, late May to early Jul in Kazakhstan, and late May in Afghanistan; single-brooded, but two broods suspected at times. Probably monogamous; more study required. Nest built by female only, a scrape lined with coarse grass stems, wool and hair, on ground and well hidden under shelter of boulder, grass tuft or small shrub, rarely up to 30 cm above ground in small shrub. Clutch 3–6 eggs, variably bluish to pinkish, with sparse brownish spots, streaks and blotches concentrated at large end; incubation by female alone, male possibly helps (male with brood patch reported); both sexes feed young; no information available on duration of incubation and nestling periods; family breaks up c. 7–8 days after young leave nest.



Movements. Migratory. Departure from breeding grounds from late Aug through Sept, a little earlier in Kazakhstan, where many leave during first half Aug. In Tajikistan migration peak in first half Sept; arrives in Pakistan in Sept, and can be abundant there. Although a few winter in Sind (S Pakistan) in years with good monsoon, great majority move E through Kutch into NW India, where they winter from N Gujarat E to C Uttar Pradesh and E Maharashtra, S to N Andhra Pradesh and C Karnataka; as races not separable in non-breeding plumage, assumed that all winter together in W India, although likely discrete areas exist where each race predominates. Return passage evident through Mar in Kutch, with birds back on breeding sites by end Mar in S Baluchistan, late Apr in E Turkey, Iran and C Afghanistan. Passage throughout Apr and May through Kazakhstan. Vagrants recorded in Sri Lanka, the UAE, Kuwait, W Siberia, Finland, Sweden, Norway, Germany (Heligoland), Netherlands and Cyprus; also (race *cerrutii*) in Dagestan and Stavropol Krai; one in Vietnam in 2006, the first record for SE Asia.
Status and Conservation. Not globally threatened. Abundant in many areas; somewhat localized over extensive range. Migration studies at Chokpak Pass, in W Tien Shan of Kazakhstan, indicate considerable drop in numbers passing through since 1940s. Reasons for this unclear, but overgrazing of sparse vegetation of its semi-arid habitats by domestic animals may be a contributing factor.

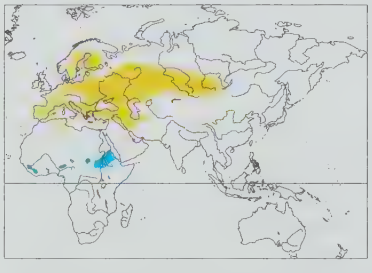
18. Cinereous Bunting

Emberiza cineracea

French: Bruant cendré **German**: Türkenammer **Spanish**: Escribano Cinéreo
Other common names: Grey-headed/Ashy-headed Bunting

Taxonomy. *Emberiza cineracea* C. L. Brehm, 1855, Izmir, Turkey.
Forms a species group with *E. buchanani*, *E. hortulana* and *E. caesia*. Observations of apparent intermediate individuals on passage indicates that races intergrade in some unknown part of range. Two subspecies recognized.
Subspecies and Distribution.
E. c. cineracea C. L. Brehm, 1855 – breeds SW Turkey and adjacent E Greek islands of Skyros, Lesbos and Chios; winters in Sudan, Eritrea and S Saudi Arabia.
E. c. semenowi Zarudny, 1904 – breeds SE Turkey and SW Iran; probably winters SW Arabia.



Descriptive notes. 16·5–18 cm; 21–29·7 g. Relatively large, long-bodied, but rather featureless bunting with fairly long bill. Male nominate race has forehead, crown, ear-coverts, side of head and nape yellowish-grey, forming ill-defined hood; chin and throat clear light yellow, pale yellow eyering; lores indistinctly paler and malar stripe ill defined, giving otherwise plain-faced appearance; upperparts medium grey, weakly streaked darker on mantle, with rump and uppertail-coverts virtually unstreaked purer grey; upperwing browner grey, each feather with blackish centre and light buff border, creating indistinct pale wingbars at tips of median and greater coverts (in fresh, non-breeding plumage wings cleaner and more boldly patterned); tail blackish-brown, white over distal portion of inner webs of two outermost pairs of feathers; breast brownish-grey, colour extending onto upper flanks, sometimes washed pale greenish-yellow; remainder of underparts, including undertail-coverts, off-white; iris dark brown, narrow but clear light yellow eyering; bill pale grey; legs flesh-pink. Female is duller than male, with dull brownish-grey hood and pale buff-yellow (rather than clear yellow) on lores and throat, but malar stripe more conspicuous than on male. Juvenile is similar to non-breeding female, but crown and upperparts more strongly speckled and streaked; bill pale grey, as on adult, not pale pink. Race *semenowi* has entire head and underparts washed with brighter yellow. Voice. Song, from prominent boulder, treetop or bush, an insignificant little phrase consisting of 4–6 notes, first few notes increasing in volume, last two longer, weaker and descending in pitch, "drip-drip-drip-drieeh-drieeh"; reminiscent of rapid abbreviated song of *E. citrinella* or *E. hortulana*, but sharper in tone than either. Calls include weak, but rather harsh, "tsik", short "quip" like that of *E. hortulana*, and descending "tieu", the last recalling one of the calls of *E. citrinella*.
Habitat. Breeds in dry, hilly country with scattered rocks and shrubby cover. In winter in open country and coastal lowlands, as well as rocky foothills of desert and semi-desert with sparse grasses and other scant vegetation, including fringes of dry cultivation.
Food and Feeding. Poorly studied. Feeds chiefly on invertebrates during breeding season, otherwise primarily on seeds. In late May stomach contents of three specimens composed of caterpillars (Lepidoptera), flies (Diptera), small beetles (Coleoptera) and small snails (Pulmonata); Apr specimens contained mixture of seeds and invertebrates, contents of three out of eight stomachs being entirely seeds. Forages on ground, often loosely associating with parties of *E. hortulana* and *E. caesia* when on passage. Otherwise solitary or in small family parties of 4–5, rarely as many as ten together, and once (exceptionally) 40 in Israel.
Breeding. Little information. Eggs reported late Apr in SW Iran and W Turkey and late May in E Turkey, where recently fledged young noted as late as mid-Aug. Probably monogamous. Nest construction probably by female only, though male often in attendance; nest a foundation of grass seedheads, stalks and thistle leaves, lined with hair and rootlets, placed on ground against rock or concealed by tuft of vegetation. Clutch 4–6 eggs, light bluish with small speckles and scrawls. No other information.
Movements. Migratory. All breeding areas vacated from late Aug onwards. The two races differ somewhat in their migration routes and winter ranges, although a certain amount of intermingling takes place at passage stopovers. At well-studied locations in Israel, through passage from mid-Mar to mid-May and again in first half Sept; both races much more evident in spring than in autumn. Nominate race arrives on breeding grounds in early Apr, having taken a route from its winter quarters in coastal Eritrea and adjacent NE Sudan (perhaps this race also in NE Ethiopia); moves N along shores of Red Sea, through Levant and into S Turkey, then W to SW Turkey; seems to avoid migrating across E Mediterranean, as indicated by scarcity of records from Cyprus. E race *semenowi* reported on breeding grounds as early as late Feb, probably having travelled along Persian Gulf from winter quarters in SW Saudi Arabia and Yemen. Unclear whether mixed-race flocks form in winter or only on passage, but in N & C Israel *semenowi* extremely rare; in S Israel its occurrence varies from year to year, e.g. at Eilat as many as 30–40% are *semenowi* in some springs, whereas in other years this race absent. Considering the species' limited range, a remarkable number of vagrants reported: individuals recorded Tunisia, Denmark, Heligoland (Germany), Oman and Samarkand (Uzbekistan); report from E Afghanistan requires adequate documentation, as it concerns two individuals in mid-winter (other documented vagrants seem to have involved overshooting on spring migration).
Status and Conservation. Not globally threatened. Currently considered Near-threatened. A little-known, unobtrusive species with low population density and fragmented range. Generally uncommon or rare, even in core of range. Density of 8 pairs/20 ha estimated in study area in Turkey. In Greece c. 115–305 pairs breed on three Aegean islands (Skyros, Lesbos and Chios) close to Turkish mainland. Turkish breeding population, estimated as between 2500 and 7500 pairs, thought to have declined by as much as 19% during 1990–2000. Presence as a breeding species in N Syria and Iraq requires confirmation. In Zagros Mts, in SW Iran, population could be as low as 100 pairs. Winter distribution poorly known, but includes Eritrea and Yemen, and potentially also NE Ethiopia, NE Sudan and SW Saudi Arabia (where records may relate solely to individuals on migration). In Turkey, continuing loss of habitat through development for tourism has had considerable impact over W of its range, and suitable habitats in SE Turkey have been lost through dam construction, not only because of subsequent flooding of the land, but also because of resettlement of displaced villagers and their livestock to previously under-populated areas. Resulting grazing levels should be monitored, as high grazing pressure could result in trampling of nests, whereas insufficient grazing promotes lusher vegetation, thus reducing availability of open feeding sites. The species is legally protected under Greek and Turkish laws, and one of its breeding sites on Lesbos is partially protected as a Natural Monument and Wildlife Refuge.
Bibliography. Anon. (2010c), Bruun (1984), Butchart & Stattersfield (2004), Byers, Olsson & Curson (1995), Castell & Castell (2009), Chappuis *et al.* (1973), Cramp & Perrins (1994), Fry & Keith (2004), Glutz von Blotzheim & Bauer (1997), Hagemeijer & Blair (1997), Hölzinger (1995), Kirwan *et al.* (2008), de Knijff (1991), Mauersberger (1956), Möller & Richardson (1994), Onmus *et al.* (2009), Rosetaar (1995), Shirihai (1996), Stattersfield & Capper (2000), Tucker & Heath (1994), Wallschläger (1983), Walther (2006), Walther *et al.* (2004).

19. Ortolan Bunting

Emberiza hortulana

French: Bruant ortolan **German**: Ortolan **Spanish**: Escribano Hortelano

Taxonomy. *Emberiza hortulana* Linnaeus, 1758, Sweden.
Forms a species group with *E. buchanani*, *E. cineracea* and *E. caesia*. Proposed race *elisabethae* (Uliastai, in NW Mongolia) claimed to differ in colour intensity, but these differences seem to be due to individual variability. Monotypic.
Distribution. Breeds in Europe from N Fennoscandia (almost reaching Arctic Circle) S, very patchily, to N Portugal, C Spain (including Balearic Is), S France, N Italy, Greece, Crete, Turkey and N Israel, extending E across European Russia, Ukraine and N Caspian region to N Kazakhstan and Altai and Khangai Ranges in NW & WC Mongolia and, in S, through Caucasus, N Iraq and N Iran to borders of Turkmenistan; also N Africa (coastal Algeria). Non-breeding range not well known, probably mountains along S fringes of Sahara, where recorded Sierra Leone, Guinea, Ghana and Nigeria in W, and E Chad and SE Sudan E to Ethiopia and Eritrea in E, and probably includes Yemen and Oman.

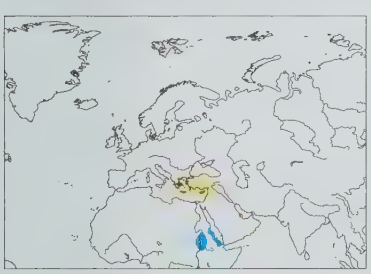
Descriptive notes. 16–17 cm; 17–28·1 g. Relatively stocky bunting with comparatively short tail. Male in spring (plumage worn) has olive or greyish-olive head and breast, contrasting with light yellow throat and submoustachial stripe, and unstreaked rufous lower underparts; some (especially in N Turkey and Armenia) are distinctly grey on head and may have whitish throat; upperparts, including wing, dull brown, quite strongly streaked with black; tail blackish, white areas towards tip of outermost three feather pairs; iris dark brown, narrow but clear pale yellow eyering; bill pale pink; legs flesh-pink. Differs from *E. caesia* in having yellow (rather than orange) throat and submoustachial stripe, dull brown (not rusty) rump, also usually olive-toned (not blue-grey) head and breast. Female in spring is similar to male, but less bright, with some streaking on crown and nape and dark malar stripe; may lack olive breastband, latter being obscured by diffuse streaking. Male in fresh non-breeding plumage (autumn) has dusky malar stripe and dark streaking on crown and nape; resembles female, but underparts more colourful (though sexing of many autumn birds often tricky). Juvenile is very dull, with rufous-buff ground colour of lower underparts, boldly streaked across breast, more finely so on flanks, bill greyish at first but soon becoming pinkish; first-autumn bird similar to adult female but tends to be more heavily streaked, although variation makes ageing difficult. Voice. Song, from prominent treetop or bush, rarely in short song flight, a short phrase of 5–6 notes, with ringing quality in first 2–3 notes, dropping in pitch with final two, can be transcribed as "swee-swee-swee, dee-dee"; varies individually and geographically, but basically recalls an abbreviated version of *E. citrinella* song. Calls include clear, ringing disyllabic "tsleeu" (the principal flight call), short incisive "quip" or "pwit" (generally given by flushed migrants) and short "chu" (often accompanies "tsleeu" call).
Habitat. Breeds in lightly wooded dry, open country, both in plains and on hill and mountain slopes, reaching elevations of up to 2500 m; breeding range lies within Jul isotherms of 15–30°C. Habitats vary over extensive range: in many parts of Europe favours open cultivation, with scattered trees and bushes, and unmade farm tracks between small weedy fields; more locally found in forest clearings, but in general avoids extensive forests and coastal areas. On migration, in Mongolia, can be found resting in open desert-steppe. In winter found in semi-arid cultivation, especially in open upland habitats between 1000 m and 3000 m.
Food and Feeding. During breeding season feeds chiefly on wide variety of invertebrates, including ants (Formicidae), beetles (Coleoptera) and grasshoppers (Orthoptera); otherwise primarily on seeds. Typically, forages both on ground and among foliage of bushes, and even in canopy of trees, notably oaks (*Quercus*), which are particularly rich in variety and abundance of caterpillars (Lepidoptera), an important food source for rearing young. Also, often makes flycatching sallies from bushes or trees. Often solitary, but even in breeding season small parties may gather at important feeding spots. In late summer forms small groups, by early autumn these merging to create larger flocks of up to several hundred individuals, remaining together through winter. On migration sometimes in larger gatherings, in Israel e.g. roosts of up to 800 birds in Sept and occasionally thousands together at stopover sites (such as oases) in spring; associates with *E. caesia* on passage.
Breeding. Eggs reported from mid-Apr in S of range, until early Jun in N. Monogamous, rarely polygamous; pair-bond lasts for one season only. Nest construction by female only, male often in

attendance, nest a cup of rootlets and grasses, lined with finer materials, placed in relatively deep depression on ground, often in field of growing crops. Clutch 4–5 eggs, pale blue to pink or greyish, with dark spots scrawls and speckles sometimes forming ring around large end; incubation by female, period 11–12 days; chicks tended by both parents, nestling period 12–13 days.

Movements. Migratory; after breeding, moves to N part of sub-Saharan Africa. Breeding areas vacated from mid-Jul onwards, most leaving from mid-Aug to mid-Sept. W populations move through coastal Morocco from late Sept to mid-Oct, and farther S passage through Mauritania, Senegambia and Mali reported up to late Nov, rarely into Dec; these seem to winter in mountain ranges of Sierra Leone and Guinea, with a handful of reports from Nigeria. On the whole little is known of range across C Africa. E populations winter in highlands of Ethiopia, Eritrea and probably adjacent S Sudan and N Yemen, but relatively little known: arrive in C Ethiopia early Oct, having left breeding sites in W Siberia from late Jul onwards; studies at Chokpak Pass (SE Kazakhstan) determined that first-year individuals move through before adults, with peak passage in early Sept; passage continues SW on relatively broad front over Iran, Iraq and Arabia. Spring migration of W populations more conspicuous than that in autumn, moving through W Mediterranean region late Mar to mid-May, peak first half of Apr; arrival in extreme N breeding areas (N Sweden) from mid-May, some not until early Jun. Regular scarce migrant in British Is (chiefly in Sept). Vagrants have reached Faeroe Is, Iceland, Canary Is, Irkutsk (vicinity of L Baikal), Japan, Hong Kong, N Pakistan, N India, Seychelles and Kenya.

Status and Conservation. Not globally threatened. Widespread and abundant. Following estimates for W Palearctic populations (numbers of pairs) based mostly on surveys in late 1980s: Norway 100–300, Sweden 25,000–100,000, Finland 150,000–200,000, Estonia 5000–10,000, Latvia 500–2000, France 10,000–23,000, Belgium 2–3 pairs (1994), Germany 4000–5000 (but 10,000–14,000 pairs estimated in 2005), Poland 10,000–100,000, Czech Republic 200–300, Hungary 10–30, Switzerland 200–250, Austria up to 50, Italy 4000–8000, Croatia 1500–2500, Slovenia 300–500, Bulgaria 10,000–100,000, Romania 15,000–25,000, European Russia 10,000–100,000, Belarus 1000–3000, Ukraine 800–2500, Moldova 6000–8000, Spain 200,000–250,000, Portugal 1000–10,000, Albania 1000–10,000, Greece 20,000–30,000, Turkey 1,000,000–10,000,000; in addition, reported as common in Lithuania, common locally in Azerbaijan, fewer than five pairs in Slovakia, and 6–8 pairs in Israel. No longer breeds in Denmark and Netherlands, and now merely a sporadic breeder in SE Norway and Belgium. Very local in Germany, Switzerland and Austria; localized but increasing in Gulf of Bothnia (Sweden); more widespread over E Europe E from Poland. Considered to have decreased in most W & C European countries since 1930s, especially since mid-1960s; decrease believed due to intensification of agriculture, including changes in land use, less crop diversity, the loss of hedgerows (making larger fields), and extensive use of pesticides. No indication of a decrease in C Asian populations, but few data.

Åstrom & Stolt (1993), Berg (2008), Bernardy *et al.* (2008), Bezzel (1993), Brokhovich (1990), Brotons *et al.* (2008), Busche (2005), Byers, Olsson & Curson (1995), Castell & Castell (2009), Claessens (1992), Conrads (1976), Conrads & Conrads (1971), Conrads & Quelle (1986), Cramp & Perrins (1994), Dale (2009, 2010, 2011), Dale & Christiansen (2010), Dale & Hagen (1997), Dale & Olsen (2002), Dale *et al.* (2005), Dementiev *et al.* (1954, 1970), Eber & Szijj (1960), Fonderflick & Thévenot (2002), Fonderflick *et al.* (2005), Fry & Keith (2004), Glutz von Blotzheim & Bauer (1997), Grimm (2008), de Groot *et al.* (2010), Grützmann *et al.* (2002), Guerrieri *et al.* (2006), Haffer (1989), Hagemeijer & Blair (1997), Hänel (2004), Kirwan *et al.* (2008), Kuzniak *et al.* (1997), Lanz (2009), Lister (2007), Mascher & Stolt (1961), McGregor (2004), Menz, Brotons & Arlettaz (2009), Menz, Mosimann-Kampe & Arlettaz (2009), van Noorden (1999), Osiejuk, Ratynska, Cygan & Dale (2003a, 2003b, 2005), Osiejuk, Ratynska, Dale *et al.* (2004), Ottvall *et al.* (2008), Revaz *et al.* (2005), Roselaar (1995), Skierczynski & Osiejuk (2010), Small (1992), Stolt (1977, 1987, 1993), Stolt & Fransson (1995), Tucker & Heath (1994), Vepsalainen *et al.* (2005), Welch (2010), Yamada (2006), Yosef & Tryjanowski (2002a).



20. Cretzschmar's Bunting

Emberiza caesia

French: Bruant cendrillard **German**: Grauortolan **Spanish**: Escribano Ceniciento

Taxonomy. *Emberiza caesia* Cretzschmar, 1827, Kurgos Island, c. 17° N, River Nile, Sudan.
Forms a species group with *E. buchanani*, *E. cineracea* and *E. hortulana*. Monotypic.

Distribution. Breeds SW Albania, most of Greece, Crete, much of coastal W & S Turkey, Cyprus, W Syria, Lebanon, W Jordan, N Israel and Palestine; possibly also NW Iraq. Winters in Sudan both on coast and along Nile Valley; some reported S Egypt, NW & SW Saudi Arabia and Eritrea.

Descriptive notes. 16 cm; 18·5–23·5 g. Male breeding has grey-blue hood, breast and malar stripe, contrasting orange-rufous lores, chin, throat and submoustachial stripe, remaining underparts orange-rufous; upperparts warm rufous to buffy brown with blackish feather centres (streaked appearance), brightest rufous on unmarked rump and weakly marked uppertail-coverts; wing feathers blackish with pale fringes (indistinct wingbars); tail blackish, white areas towards tip of outermost three feather pairs; iris dark brown, narrow but clear pale eyering; bill light pink, culmen and tip usually greyer and often darker; legs flesh-pink. Differs from *E. hortulana* mainly in more richly coloured plumage, slightly longer tail, shorter wing and smaller bill. Male non-breeding is very like breeding, but somewhat duller, rump and belly a little paler, crown often streaked (variable). Female breeding is less bright than male, with sandy-brown wash as well as fine streaking on crown and breastband; grey of nape diffuses into rufous-brown on mantle (division being sharper on male). Female non-breeding is very like breeding, but duller, paler and more streaked. Juvenile plumage is short-lived, dull buff overall, streaked dark brown on both upperparts and underparts. Voice. Song, from prominent rock, tree or bush, a short phrase of 3 or 4 notes, "dziree-dziree-dzireee", similar to that of *E. hortulana* but somewhat lower in pitch, a little harsher and with a buzzing (rather than ringing) quality. Main call a sharp "tchipp", harder and sharper and less metallic in tone than that of *E. hortulana*; other calls include hard and sharp "tchu" and hard "plet", latter like that of *E. hortulana*.

Habitat. For breeding favours coastal habitats, including small islands, with boulder-strewn hillsides, usually with sparse vegetation, below 1300 m; in drier, more stony country than that preferred by *E. hortulana*. Successfully competes with *E. hortulana* where ranges meet, latter being forced to breed at higher elevations. In winter found in dry open country such as grassy plains and savanna, semi-arid cultivation and wadis.

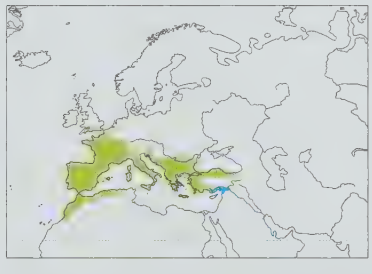
Food and Feeding. Diet little studied, but known to consist of wide variety of small seeds, especially of grasses (Poaceae); some invertebrates also taken, notably ants (Formicidae) at times of emergence of alate swarms. Forages almost entirely on ground; unlike *E. hortulana*, does not forage in foliage or perform aerial flycatching. Small parties merge to form quite substantial gatherings (up to several hundred individuals) in autumn and winter, when mixed flocks with *E. hortulana* occur.

Breeding. Eggs reported from mid-Apr to mid-Jun in Greece and Cyprus; in N Israel, eggs reported as early as late Mar and as late as mid-Jul, with two broods regularly reared. Nest built by female, a cup of dried grasses and rootlets, thickly lined with finer materials, placed on ground in relatively deep depression against rock or among roots of shrubby plant. Clutch 4–5 eggs, sometimes 6, off-white with variable yellow to pinkish tinge, with dark spots, lines and small blotches and faint greyish underlying smears; incubation mainly by female, period 12–14 days; male helps to tend young, nestling period 12–13 days.

Movements. Migratory; post-breeding movement chiefly to Nile Valley and Red Sea coast of Sudan. Breeding areas vacated in Jul and Aug, some juveniles leaving as early as mid-Jun in Israel, with late birds in S Egypt until early Nov; migrates on broad front both over and around E Mediterranean. Arrives in Sudan winter quarters in Sept. Spring migration chiefly Mar and Apr in E Mediterranean region in general. For a species with such a restricted breeding range, surprisingly prone to vagrancy: reported from British Is, France, Netherlands, Germany, Sweden, Finland, Poland, Austria, Bulgaria, Malta, Algeria, Libya, Chad, Kuwait, UAE, Iran, Oman, Georgia, Canary Is, possibly also Kenya; also S Russia (Caucasian shore of Black Sea). Some W European records, at least, may refer to escaped cagebirds.

Status and Conservation. Not globally threatened. Locally common, and comparatively numerous throughout much of range; uncommon in Jordan. Global population has been tentatively estimated at between 447,000 and 920,000 individuals. Following country estimates have been made: Albania fewer than 500 pairs, Greece 5000–15,000 pairs, Turkey 10,000–100,000 pairs, Cyprus 10,000–20,000 pairs, Israel a few thousand pairs. No figures available for Syria and Lebanon. No obvious threats.

Bibliography. van den Berg & Damhuis (1981), Byers, Olsson & Curson (1995), Castell (1997), Castell & Castell (2009), Cichocki (1988), Cramp & Perrins (1994), Daskaleva (2007), Dementiev *et al.* (1954, 1970), Dennis (1969), Donnelly (2008), Fry & Keith (2004), Glutz von Blotzheim & Bauer (1997), Haffer (1989), Hagemeijer & Blair (1997), Holloway (1998), Kirwan *et al.* (2008), Klinge *et al.* (1997), Koblik *et al.* (2006), Mauersberger (1960c), Oddie (1981), Robel (1997), Roselaar (1995), Shirihai (1996), Small (1992), Tucker & Heath (1994), Yosef & Tryjanowski (2002b).



21. Cirl Bunting

Emberiza cirlus

French: Bruant zizi **German**: Zaunammer **Spanish**: Escribano Soteño

Taxonomy. *Emberiza cirlus* Linnaeus, 1766, southern Europe.
Recent phylogenetic analysis suggests that this species may form an independent subclade within a clade shared with *E. citrinella*, *E. leucocephalos* and *E. stewarti*, but with weak support under different analytic approaches. Proposed races *nigrostriata* (described from Ghisonaccia, in Corsica) and *portucaliae* (from Oporto region, in Portugal) considered to exhibit only very slight differences from birds in rest of range, and not sufficient to merit naming of geographical races. Treated as monotypic.

Distribution. Temperate areas of W & S Europe, NW Africa and Turkey: SW England and NW & C France E to Romania and coastal W & N Turkey, S to Morocco, coastal Algeria and NW Tunisia, and to Mediterranean islands of Balearics, Corsica, Sardinia, Sicily and Crete.
Introduced to New Zealand (South Island).

Descriptive notes. 15–16·5 cm; 20–29 g. Medium-sized slim bunting, slightly smaller than *E. citrinella* and with proportionately shorter tail. Male breeding (worn plumage) has distinctive head pattern of greyish-green crown to nape with fine black streaking, black eyestripe enclosed by long yellow supercilium and long yellow stripe from bill back to rear ear-coverts, and black chin and throat; upperparts chestnut with black feather centres and light olive edges, rump is greyish-olive or pale brownish-grey and unstreaked or very lightly streaked; upperwing feathers with paler edges, tertials black with broad rufous fringes; tail brownish-black with whitish edges, outer two feather pairs with white on inner webs; upper breast yellow, bordered below by broad olive-green band, side of breast chestnut, lower breast and belly pale yellow, becoming whitish on undertail-coverts, flanks streaked brown; iris dark brown; bill blackish-grey above, lower mandible pale bluish-grey with some blackish-grey on underside; legs brownish-pink. Male non-breeding (fresh plumage) has pattern somewhat obscured by pale feather tips, especially on head, where black feathering tipped buffish. Female is superficially similar to male, but with head and breast patterns far less distinctive: supercilium paler, eyestripe greyish-brown, ear-coverts pale yellow, chin and throat yellowish and bordered by narrow malar stripe; upperparts as on male, but paler, uppertail-coverts with dark shaft streaks; underparts pale olive-grey, side of breast light rufous, lower underparts pale yellowish, all except belly with dark streaks. Typical female is rather similar to female *E. citrinella*, but ground colour appears more buffish than yellow and streaking below is sharper. Juvenile is similar to female, but generally paler and greyer above, and already has well-developed dark eyestripe and dark moustachial stripe (distinguishing it from rather similar juvenile of *E. citrinella*), hint of rufous on scapulars, and paler brown rump and edges of tertials (chestnut on *E. citrinella*); first-winter male is very like adult female, but with more rich colour on flanks and breast, and greener lesser upperwing-coverts. Voice. Song, usually from bush, tree or wire, consists of a long trilling rattle, "sre-sre-sre-sre-sre-sre-sre-sre-sre-sre", rather metallic and at constant pitch, repeated typically in series of 10–20, at a distance reminiscent to some extent of song of Arctic Warbler (*Phylloscopus borealis*) or Western Bonelli's Warbler (*Phylloscopus bonelli*). Call a fine clicking "ziit", and sometimes a "siiuu" like that of *E. schoeniclus*.

Habitat. Usually linked to areas of bushes and small woodlands surrounded by open landscape, and edges of forest and various types of farmland such as vineyards, fruit trees and others, where scrub and herbs present at borders of fields, and on roadside verges; often in hilly areas, but also on flat ground. In N of range generally in places more exposed to S, as well as with more sheltered areas and tree cover, than sites favoured by *E. citrinella*. In S reaches 1500 m in montane habitats, and occupies more diverse array of habitats. In winter shows preference for fallow fields or stubble. Detailed analysis of habitat preferences in Italy revealed that distribution was positively influenced by extent of arable land, grassland and mixed woodland, and negatively by urbanized land and orchards, indicating importance of low-intensity farming.

Food and Feeding. Adults take invertebrates during breeding season, but for most of year feed on seeds of herbs and grasses, preferably couch (*Elymus*), rye-grass (*Lolium*), meadow-grass (*Poa*), and several types of cereal grains. Nestling diet mostly invertebrates, including mayflies (Ephemeroptera), grasshoppers (Orthoptera), earwigs (Dermaptera), bugs (Hemiptera), lacewings (Neuroptera), several types of Lepidoptera, flies (Diptera), ants, wasps and sawflies (Hymenoptera), spiders (Araneae), earthworms (Lumbricidae) and snails (Pulmonata). Plant material identified includes, among others, seeds or fruits of olive (*Olea*), nettle (*Urtica*), knotgrass (*Polygonum*), bindweed (*Fallopia*), chickweed (*Stellaria*), bittersweet (*Solanum*), groundsel (*Senecio*), several kind of grasses and mosses. Forages mostly on ground, generally near cover of bush or hedge; sometimes climbs on stems of cereals or herbs to reach tips of plants (where seeds available). In non-breeding season usually in small flocks, generally of fewer than ten individuals, very occasionally up to c. 50; often mixed with other buntings and finches (Fringillidae).

Breeding. Season long, first nests started from mid-Apr and last ones during Aug, exceptionally beginning Sept; usually two broods, sometimes three. Nest probably built entirely by female, taking 4–6 days, a bulky cup of stalks, grasses, dry roots and moss, lined with fine grass and hair, placed low down, usually below 2 m (but not normally on ground), in dense thorny shrub, conifer or behind similar kind of concealing vegetation on wall, or sometimes in deciduous tree. Clutch 2–5 eggs, most commonly 3–4, greyish-white with many sepia spots and streaks; incubation by female, period 12–13 days; chicks fed by both sexes, nestling period 11–13 days. Of 86 eggs in study in E Spain (Valencia), 65% hatched and 31% produced fledged young; of 73 nests in German study 37% failed, losses due mainly to predation by domestic cats, Eurasian Jay (*Garrulus glandarius*) and Red-backed Shrike (*Lanius collurio*), also inclement weather and disturbance from farming activities.

Movements. Those breeding in N part of range partially migratory; resident in S. Ringing studies have provided a number of long-distance recoveries, mainly of birds moving S or W for winter; longest movement recorded 725 km, from Belgium to SW France. Colour-ringing studies in small British population (in Devon) reveal that, in general, birds winter within a few kilometres of breeding sites. Some altitudinal movement, with post-breeding descent from montane areas to lowlands. Also, some arrive in winter in coastal areas in milder parts of Mediterranean Basin; origin of these not known, but possibly related to altitudinal movements or involve partial migrants. Migrants noted at Strait of Gibraltar (in S Spain) and in Col de Bretolet (Switzerland), and vagrants recorded S to Canary Is, Malta and Egypt; elsewhere recorded as vagrant E to Denmark, Poland, Russia, Czech Republic and Crimea, and in Tula Oblast (W Russia).

Status and Conservation. Not globally threatened. Locally common; scarce and very local in NW of range. Estimated population in Europe (more than 95% of global range) c. 2,000,000–5,200,000 pairs. Introduced in New Zealand in late 1800s; now successfully established, mainly in South I. Breeding densities during five-year study in orange groves in E Spain varied from 0·6 to 10·1 pairs/ha, being positively correlated with rainfall (but not to temperatures) during previous Dec–Mar period (rainfall leading to increase in food supply). Despite moderate increase in numbers in several countries during 1970–1990, present data suggest that population is stable, as apparently was the case in Spain and Italy during first years of 21st century. Since 1960s a decline was evident in, especially, N of range; in Britain, where the species bred widely in S England and Wales, its range contracted greatly, until it was finally confined to a handful of pairs in a small area in SW (S Devon); conservation work, principally in the form of habitat management, has succeeded in raising the population to more than 849–862 "territories" in 2009, although little evidence of range expansion has been recorded. Throughout its range, some factors, such as loss of traditional farming, the intensification of agriculture and an increase in forest cover, could have adverse effects in the future.

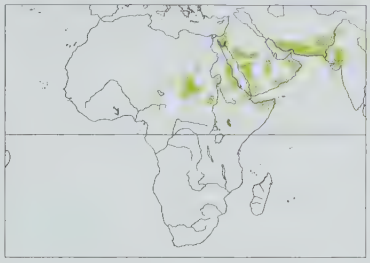
22. House Bunting

Emberiza sahari

French: Bruant du Sahara **German**: Hausammer **Spanish**: Escribano Sahariano

Taxonomy. *Emberiza sahari* J. Levaillant, 1850, near Ghelma, between Ghardaïa and Ouargla, southern Algeria.
Often treated as conspecific with *E. striolata*, but constant differences in plumage and behaviour. Exhibits some variation in plumage tone: more richly coloured birds from SW Morocco sometimes treated as race *theresae* (described from Anja, in SW Morocco) and darker ones from S Mali as *sanghae* (from Sangha, near Bandiagara, in Mopti, in S Mali), but differences considered minimal. Treated as monotypic.
Distribution. NW Africa from Morocco and Mauritania patchily E to NW Chad.



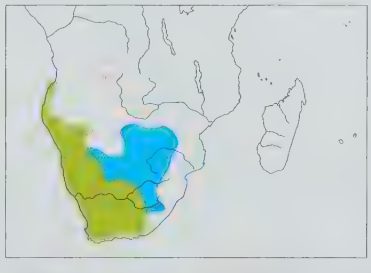
Descriptive notes. 13–14 cm; 12–18 g. A rather small, slender bunting, smaller than *E. cia* and with rather plain face, rufous upperwing-coverts and secondaries lacking blackish feather centres; outer tail edged rufous (not white). Male has head, neck, throat and upper breast grey, finely streaked blackish, slightly paler supercilium, cheek stripe and submoustachial stripe all contrasting little with darker side of crown, eyestripe, moustache and malar; whitish spot on rear ear-coverts; upperparts rich cinnamon-rufous, diffuse grey-brown mottling on mantle; flight-feathers dark brown with cinnamon margins; lower breast and belly rich cinnamon; iris dark reddish-brown; bill blackish above, yellow or pinkish below; legs pale pinkish-brown. Differs from *E. striolata* in much plainer plumage and less strikingly patterned head. Female is duller, with dull brownish head, streaked darker on crown; supercilium buffy. Juvenile is slightly duller than female, has bill uniformly coloured. Voice. Male song, throughout year but most intense prior to breeding, a series of simple notes, similar to that of *E. striolata* but tends to be more varied, with 2–3 repeated elements, and often slightly lower-pitched. Call "dzwii".
Habitat. Rocky areas, usually near water. Closely associated with human dwellings in much of its range, but occurs also around natural rock outcrops and wadis. At up to 2300 m in Atlas Mts in Morocco.
Food and Feeding. Diet mainly seeds, also occasional flowers, berries, insects and spiders (Araneae). Frequently scavenges food around human dwellings and markets; also associated with livestock, gleaning among their feed. Forages mainly on ground.
Breeding. Late Jan to late Oct, mainly late Feb to late Jul, in Morocco; frequently multiple broods, up to four per season. Monogamous; usually retains same mate throughout a breeding season, but considerable turnover of mates between years. Territorial; male advertises territory by singing from exposed perches. Nest built by female, male may assist with collecting of material, a small cup of twigs, roots and grass stems, lined with finer material, including plant fibres, hair and wool, placed 1–3 m up in hole in old wall or cliff face; rarely on ground; often uses same nest for subsequent broods. Clutch 2–4 eggs (rarely 1–5), whitish, tinged pale green or blue, with dark brown or purple markings; no information on incubation period; chicks fed by both parents, nestling period 17–19 days; young remain on territory and fed by parents for up to 2–3 weeks after fledging. Average breeding success in Morocco 1·3–1·7 fledglings per nest (58–66% of eggs hatch, and 50–57% of hatchlings fledge); main cause of failure human disturbance. Probably starts breeding at 1 year of age.
Movements. Mostly resident; some move to lower elevations in winter in Morocco. Occasional vagrants wander well outside normal range, reaching Canary Is, S Spain and Gambia.
Status and Conservation. Not globally threatened. Locally common. Range has expanded N in previous century, up to 200 km in Morocco, with similar expansions in Algeria and Tunisia. Regarded as sacred in Morocco, and allowed to enter dwellings without hindrance.
Bibliography. Bannerman (1953), Bannerman & Priestly (1952), Barlow *et al.* (1997), Byers, Olsson & Curson (1995), Castell (2000), Castell & Castell (2009), Cave & MacDonald (1955), Collinson (2006), Courteille & Thévenot (1988), Cramp & Perrins (1994), Étchécopar & Hüe (1967), Fry & Keith (2004), Goodman & Meininger (1989), Hemetsberger (2005), Hollom *et al.* (1988), Isenmann & Moali (2000), Kirwan & Shirihai (2007), Roux *et al.* (1990), Schneider (1998, 2005), Thévenot *et al.* (2003), Traylor (1960), Uhlig (1993), Vaurie (1956), Wallis (1912).

23. Striolated Bunting

Emberiza striolata

French: Bruant striolé **German**: Wüstenammer **Spanish**: Escribano Estriado
Other common names: Striped Bunting

Taxonomy. *Fringilla striolata* M. H. C. Lichtenstein, 1823, Ambukol, Nubia, Berber, Sudan.
Often treated as conspecific with *E. sahari*, but constant differences in plumage and behaviour. Race *jebelmarrae* interpreted as an intergrade between nominate and *saturatior* by some workers, but others consider it synonymous with latter; situation complicated by considerable individual variation in plumage. Three subspecies recognized.
Subspecies and Distribution.
E. s. striolata (M. H. C. Lichtenstein, 1823) – Israel and Sinai Peninsula, Arabian Peninsula, S Iran, Pakistan and NW India, and NE Sudan, Eritrea and N Somalia.
E. s. jebelmarrae (Lynes, 1920) – NE Chad and W Sudan.
E. s. saturatior (Sharpe, 1901) – C Sudan, SW Ethiopia and NW Kenya.
Descriptive notes. 12–13 cm; 12–16 g. A small, slender bunting, smaller than *E. cia* and with more "scruffily" striped face; outer tail edged rufous (not white). Male nominate race has head, neck, throat and upper breast grey, streaked blackish, whitish supercilium, cheekstripe, submoustachial stripe and central throat (contrast of head stripes varies with feather wear; greatest in worn plumage in spring); upperparts cinnamon-rufous, heavily streaked dark grey-brown; flight-feathers dark brown with cinnamon margins; lower breast and belly washed cinnamon (typically, paler than *E. sahari*); iris brown; bill blackish above, lower mandible yellow, sometimes with dark tip; legs pale pinkish-brown. Differs from *E. sahari* in having more heavily streaked plumage and more strikingly patterned head, also on average slightly smaller, with shorter bill and tail. Female is duller than male, has sandy-brown



head streaked darker on crown, buffy supercilium; told from female *E. sahari* by more heavily streaked plumage. Juvenile is duller than female, has uniform bill. Race *saturatior* slightly larger than nominate, has darker and more heavily streaked head; *jebelmarrae* is even darker, with richer underparts, male's white head stripes are less prominent. Voice. Male song, from low bush or rock, mainly in period before and during breeding, a short, stereotyped "trip trip te-tree-cha, tre-tree-cha", lasting 1·5–2 seconds. Flight call "chielp" like that of a sparrow (*Passer*), unlike twittering flight call of *E. cia*.
Habitat. Rocky areas with arid scrub, usually near water. Typically less closely associated with human settlements than *E. sahari*, but occurs in towns and villages in Somalia and locally in Oman; occasionally breeds in ruined buildings in Asia. Habitat less restricted in winter, when may occur around cultivation.
Food and Feeding. Diet mainly seeds of grasses and herbs (e.g. *Heliotropium*), also occasional flowers, berries (*Ziziphus*) and insects. Forages mainly on ground; also takes seeds directly from grass-heads. Sometimes flutters into air to grab a stem with seedhead, pulls it to ground, and then stands on it while taking seeds. Frequently visits water to drink. Forms small flocks after breeding and in winter, often with *E. tahapisi* in S Arabia and *E. cia* in Pakistan; flock size in Israel up to 47 individuals (average eight); average 6–7 in Pakistan.
Breeding. Season Mar–Jun, sometimes to Nov, timing and extent of breeding linked to local rainfall; frequently two broods per season in Israel and up to three broods in Pakistan. Monogamous. Breeds singly; but occasionally in loose colonies with nests 10–30 m apart. Usually territorial; male advertises by singing from elevated perch, occasionally from ground. Nest built by female, although male reportedly assists in E of range, a neat cup of grass and fine plant stems, placed on ground or in crevice on rock face, site usually sheltered from sun by overhanging rock. Clutch 2–4 eggs, whitish with reddish-brown markings; incubation by female, period 12–14 days; both parents feed chicks, nestling period 12–14 days.
Movements. Resident and nomadic; subject to local movements after breeding, when small flocks wander outside breeding range. Those breeding at higher elevations often descend to lower elevations in winter (e.g. Oman, Pakistan, India). May irrupt into some areas to breed after good rains. Vagrants reach S Europe.
Status and Conservation. Not globally threatened. Fairly common; often unobtrusive and easily overlooked. Annual numbers fluctuate in Israel; this linked to rainfall, numbers falling during droughts, and increasing rapidly through combination of immigration and reproduction following good rains.
Bibliography. Ali & Ripley (1974), Archer & Godman (1961), Armani (1985), Ash & Miskell (1998), Aspinall (1996), Byers, Olsson & Curson (1995), Cave & MacDonald (1955), Collinson (2006), Cramp & Perrins (1994), Étchécopar & Hüe (1967), Fry & Eriksen (1984), Fry & Keith (2004), Goodman & Meininger (1989), Hollom *et al.* (1988), Jennings (2010), Kirwan & Shirihai (2007), Lewis & Pomeroy (1989), Pande *et al.* (2006), Roberts (1992), Shirihai (1996), Vaurie (1956).

24. Lark-like Bunting

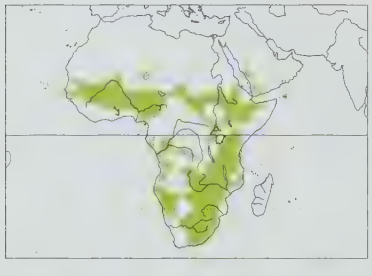
Emberiza impetuani

French: Bruant des rochers **German**: Lerchenammer **Spanish**: Escribano Alaudino

Taxonomy. *Emberiza impetuani* A. Smith, 1836, "country between Nu. Gariep and Tropic" = east Botswana.
Proposed race *eremica* (described from near Otjiwarongo, NC Namibia) subsumed into nominate. Two subspecies recognized.
Subspecies and Distribution.
E. i. impetuani A. Smith, 1836 – Angola (coastal plain S of Luanda, also locally in Moxico), Namibia, NW South Africa and W Botswana, occasionally irrupting E to Zimbabwe and N South Africa (Limpopo Province).
E. i. sloggetti (Macdonald, 1957) – W South Africa, occasionally irrupting E to Mpumalanga, Swaziland, Lesotho and S KwaZulu-Natal.

Descriptive notes. 12–14 cm; 13–19 g. A rather plain, nondescript bunting. Nominate race has head sandy brown with darker brown streaking on crown, distinctive broad buffy supercilium extending well onto nape; lower cheek also paler sandy buff; mantle and back grey-brown, streaked dark brown; upperwing-coverts dark brown with broad cinnamon margins, flight-feathers dark brown with narrow cinnamon margins; throat creamy buff, merging into sandy-buff breast and belly, breast with sparse and very narrow brown streaks; iris brown; bill dark grey above, paler blue-grey or yellowish below; legs pinkish-brown. Sexes alike. Juvenile is slightly duller than adult, with more diffuse streaking and browner breast. Race *sloggetti* is paler that nominate, with broader pale margins on upper contour feathers. Voice. Male song a fairly long series of twittering and buzzy notes lasting 2–4 seconds. Contact call a soft "chip"; alarm call a deeper "chut".
Habitat. Semi-arid grasslands and shrublands, in both rocky and sandy areas. Typically associated with the Karoo system, both W succulent Karoo and E grassy Nama-Karoo, but irrupts into more mesic habitats during droughts. Occasionally visits gardens in Karoo villages.
Food and Feeding. Diet mainly grass seeds; also some forb seeds, soft green leaves and wide diversity of invertebrates, including hairless caterpillars, termites (Isoptera), small beetles and their larvae (Coleoptera), flies (Diptera), millipedes (Diplopoda) and spiders (Araneae). Forages on ground, favouring open areas; also jumps up to pull down grass-heads. Frequently visits water to drink. Average flock size in S Karoo 31 individuals.
Breeding. Season linked to rainfall; moves into areas after rains, but breeds only if sufficient rain. Monogamous. Solitary, but nests often closely spaced (less than 20 m apart) in favourable conditions.

On following pages: 25. Cinnamon-breasted Bunting (*Emberiza tahapisi*); 26. Socotra Bunting (*Emberiza socotrana*); 27. Cape Bunting (*Emberiza capensis*); 28. Tristram's Bunting (*Emberiza tristrami*); 29. Chestnut-eared Bunting (*Emberiza fucata*); 30. Little Bunting (*Emberiza pusilla*); 31. Yellow-browed Bunting (*Emberiza chrysophrys*); 32. Rustic Bunting (*Emberiza rustica*).



Territorial; male displays by singing from prominent perch, as well as in aerial display with slow, deep wingbeats. Nest built by female, often accompanied by male, a loose cup of twigs, lined with grass seeds and rootlets, placed on ground among rocks or under small bush or grass tuft, usually on SE side shaded from sun. Clutch 2–4 eggs, rarely 5 (mean clutch size greater following good rains), whitish to pale green or pale blue, variably spotted reddish-brown and grey; incubation by female only, lasting 11–13 days; both parents feed chicks, nestling period 12–14 days. Hatching success 76%; successful nests fledge average of 2·8 chicks, but predation rates extraordinarily high (96%, over two separate studies); average breeding success only 0·08–0·1 fledglings per nest.
Movements. Nomadic, following rainfall events; small numbers resident in some areas. Migrates into more mesic areas of Western Cape in summer to breed, arriving after winter rains cease. Some irrupt well E and N of normal range during droughts. Vagrants of nominate race reach Gabon, DRCongo and W Zambia.
Status and Conservation. Not globally threatened. One of most abundant nomadic birds in the Karoo. This species' nomadic behaviour makes it hard to protect within traditional nature reserves, but it remains abundant in much of its range. Historically was caught for the cagebird trade in Namibia, where it adapted quite well to captivity.
Bibliography. Benson (1982), Bowen (1983), Boyer & Bridgeford (1988), Brewster (1997), Brickell & Arnold (1990), Brickell & Konigkramer (1997), Byers, Olsson & Curson (1995), Chapin (1954), Clancey (1989), Collett (1982), Day (1987), Dean (1997, 2000), Dean & Milton (2001), Dean & Siegfried (1997), Friedmann & Northern (1975), Fry & Keith (2004), Harrap (1970), Harrison *et al.* (1997), Hockey *et al.* (2005), Irwin (1981), Jones (1994), Kieser & Kieser (1978), Lloyd (1998, 1999), Panagis & Stutterheim (1985), Ryan *et al.* (1984), Schwarzenberger & Dean (2003), Skead, C.J. (1995), Skead, D.M. (1960, 1975), Tarboton (2001), Tyler & Tyler (2001), Vincent (1949), Winterbottom (1972).

25. Cinnamon-breasted Bunting

Emberiza tahapisi

French: Bruant cannelle **German**: Bergammer **Spanish**: Escribano Canelo
Other common names: Cinnamon-breasted Rock Bunting, African Rock Bunting

Taxonomy. *Emberiza tahapisi* A. Smith, 1836, "country towards the sources of the Vaal River", Mpumalanga, South Africa.
Race *septemstriata* sometimes thought to be a hybrid between nominate and *goslingi*. Six subspecies recognized.
Subspecies and Distribution.
E. t. goslingi (Alexander, 1906) – Mauritania and Senegal E to Cameroon, NE DRCongo and SW Sudan.
E. t. septemstriata Rüppell, 1837 – E Sudan and N & C Ethiopia E to Eritrea and NW Somalia.
E. t. arabica (Lorenz von Liburnau & Hellmayr, 1902) – S Arabia.
E. t. insularis (Ogilvie-Grant & H. O. Forbes, 1899) – Socotra I.
E. t. tahapisi A. Smith, 1836 – S Ethiopia S through E Africa to SE South Africa; also locally in Angola, and S Gabon E to S DRCongo.
E. t. nivenorum (Winterbottom, 1965) – S Angola S to C Namibia.

Descriptive notes. 13–15 cm; 11·6–21 g. A widespread Afrotropical bunting with cinnamon-washed underparts. Male nominate race has striking head pattern of black and white stripes (pattern darker and cleaner than that of either *E. sahari* or *E. striolata*); upperparts buffy brown, streaked blackish-brown, rump plainer and only lightly mottled dark brown; flight-feathers and greater uppering-coverts blackish with cinnamon-buff outer margins; throat to upper chest black, rest of underparts rich cinnamon; iris dark brown; bill dark brown or blackish-grey above, pale pink or yellowish below; legs yellowish or pinkish-brown. Female is duller and paler than male, has grey-brown head and throat streaked blackish-brown, facial stripes washed buff. Juvenile is similar to female, but even duller, with paler underparts. Race *nivenorum* is paler than nominate; *goslingi* has plain grey throat (both sexes), wing-coverts rich rufous-brown and flight-feathers with rufous bases; *septemstriata* is intermediate between *goslingi* and nominate, with some rufous in wing, male's throat mottled grey and black; *insularis* has darker lateral head stripes, smaller black throat patch, less rufous in wing, whitish underwing-coverts; *arabica* is slightly paler below than nominate. Voice. Male song a short, fast series of notes, ascending in pitch, "chip-chip-ip-ereee" or "cha-cha-cha chip", sometimes ending with buzzy trill, "chip-chip-ipereeezzzzz". Call a nasal "dwe-wer-errr" or "fair-air"; soft "twee" in flight.
Habitat. Mainly rocky hillsides, stony areas and erosion gulleys in wide range of habitats, from arid and semi-arid scrub to mesic woodland, provided adequate open ground present. Found also in sandy areas with no rocks, so long as there is adequate bare ground. Favours degraded areas, including old fields; often seen also along paths and road verges. Usually near water in arid areas.
Food and Feeding. Diet mainly grass seeds; also some soft green leaves, nectar and a wide diversity of insects, including termites (Isoptera), hairless caterpillars, beetle (Coleoptera) and wasp (Vespidae) larvae, grasshoppers (Orthoptera), adult and larval flies (Diptera), and occasional small adult beetles. Captives also ate spiders (Araneae), millipedes (Diplopoda) and small slugs (Gastropoda). Forages mainly on ground; sometimes jumps up to pull seeds from grass-heads, or clings to millet heads to strip seeds. Moves into recently burnt areas within hours of a fire. Regularly visits water to drink, especially in arid areas; has been recorded as sun-bathing, and regularly visited a salt lick.
Breeding. Season Jul–Jan (mainly Sept–Dec) in W Africa, Jan–Jun in E Africa, Apr–Jul in Malawi, Nov–Jun (mainly Jan–Feb) in Zimbabwe, Oct–Apr (mainly Dec–Jan) in South Africa, Dec–Feb on Socotra and Oct–May in S Arabia. Monogamous. Solitary, but neighbouring nests may be only 20–30 m apart in areas of high density. Territorial; male sings from prominent perch. Nest built by female, taking 4–13 days, a cup of vegetation, including grasses, twigs, dead leaves, rootlets and bark, lined with finer material, placed on ground against rock or at base of small bush or grass tuft or in rock face or earth bank; built in natural depression or excavates a shallow scrape with its body, and may use mud to cement material to ground. Clutch 2–4 eggs (rarely 5), varies regionally, e.g. 2–3 (average 2·6) in Nigeria, 2–4 (average 2·9) in Malawi and 3–4 (average 3·3) in Zimbabwe, eggs pale greenish with dark brown spots; will lay replacement clutch if first one lost; incubation usually by female only, but male of nominate race may assist, period 12–14 days; chicks fed by both parents, nestling period 13–16 days; juveniles beg from adults on natal territory for 2–3 weeks after fledging, may remain nearby for at least 2 months. Average breeding success 42% in Nigeria (mean 1·1 fledglings/nest); in Zimbabwe hatching success 66%, but only 31% of chicks fledged, losses due mainly to predation, possibly linked to nest visits by observers.
Movements. Resident, local nomad and partial migrant. In W Africa, moves N in rainy season and S in dry season. Similar movements in SC Africa, with populations breeding in both areas: mainly a summer visitor (Dec–Mar) in Botswana and Zimbabwe, but numbers peak in Zambia and Malawi after rains (Apr–Sept). Evidence of movements to lower elevations in winter in Swaziland. One bird ringed in Northern Cape (South Africa) in Jul recovered 10 months later in Zimbabwe. Report of vagrant (of race *septemstriata*) in NE Egypt (Sinai) disputed.
Status and Conservation. Not globally threatened. Uncommon to locally common. Density 0·1–0·3 pairs/ha in Eastern Cape and Nigeria, up to 3 pairs/ha in C Zimbabwe; even greater densities locally in N Nigeria. Very common on Socotra I. Range extended c. 290 km S in Ivory Coast since 1985, a result of climate change and/or habitat alteration. Persists on recently isolated habitat islands, suggesting that it is tolerant of habitat fragmentation. Caught for cagebird trade in some countries; adapts quite well to captivity. Adults occasionally caught in spider webs.
Bibliography. Anon. (2002), Archer & Godman (1961), Ash & Miskell (1998), Aspinwall (1981), Bannerman (1953), Barlow *et al.* (1997), Benson (1941, 1982), Borrow & Demey (2001), Brickell & Arnold (1990), Brickell & Konigkramer (1997), Brooks (1987), Byers, Olsson & Curson (1995), Castell & Castell (2009), Chapin (1954), Cheke & Walsh (1996), Cumming & Steyn (1966), Dean (1987, 1997, 2000), Dean & Bond (1994), Dobson (1988), Elgood, Fry & Dowsett (1973), Elgood, Heigham *et al.* (1994), Friedmann & Northern (1975), Fry (1971), Fry & Keith (2004), Gartshore (1975), Goodman & Meininger (1989), Grimes (1987), Harrison *et al.* (1997), Haydock (1949), Hockey *et al.* (2005), Hollom *et al.* (1988), Irwin (1981), Jennings (2010), Kennedy (1969), Lawson & Edmonds (1983), Lewis & Pomeroy (1989), McGregor *et al.* (2007), Oatley (1996), Osiejuk (2011), Panagis & Stutterheim (1985), Pettet (1977), Read (1982), Salewski *et al.* (2001), Scholte (1994), Serle (1940), Skead, C.J. 26. Socotra Bunting

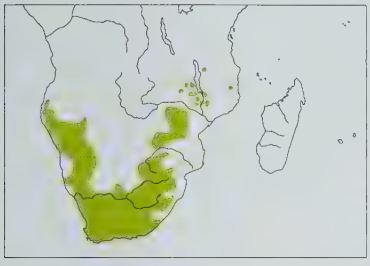
Emberiza socotrana

French: Bruant de Socotra **German**: Sokotraammer **Spanish**: Escribano de Socotora
Other common names: Socotra Mountain Bunting

Taxonomy. *Fringillaria socotrana* Ogilvie-Grant and H. O. Forbes, 1899, Adho Dimellus, 4000 feet [c. 1220 m], Socotra.
Monotypic.
Distribution. Socotra I.

Descriptive notes. 13–14 cm; 13–16 g. Male has striking head pattern of black and white stripes; grey-brown mantle streaked blackish-brown, back pale grey with blackish chevrons, rump pale grey with diffuse dark streaks; upperwing-coverts chestnut-brown, greater coverts with dark brown inner webs; flight-feathers dark brown with rufous outer margins; throat whitish, contrasting with rich cinnamon breast, which grades into whitish on belly; iris dark brown; upper mandible dark brown, lower mandible horn-yellow; legs yellowish-horn. Distinguished from *E. tahapisi* by rich chestnut wing-coverts, whitish throat, rather pale (not cinnamon-washed) belly, and pale grey rump band, with black head stripes typically narrower, and a narrow black malar stripe. Female is slightly duller than male, with dark head stripes brownish-black, but often indistinguishable in field. Juvenile is much duller than adult, with grey-brown head stripes with darker streaks, cheekstripe washed brown, throat off-white, merging into warm buff-brown breast with faint darker streaking, belly creamy with buff wash on flanks; lower mandible pale horn, legs pinkish-brown. Voice. Male song a clear "tseeto tee too" or "tseit tsoo tsee tsoo". Juvenile gives high-pitched "tseeep".
Habitat. Favours rocky hill slopes with relatively dense grass and shrub vegetation; sometimes found close to stock posts, but this may be result of similar habitat preferences by herdsmen in the region. Breeds from 600 m to above 1200 m, mainly in Hajhir (Hagghier) Range and Ma'lih Plateau. Moves to lower elevations in non-breeding season, when may occur on coastal plain.
Food and Feeding. Diet mainly grass seeds. Forages on ground; also takes seeds direct from grass-heads. In small flocks in non-breeding season.
Breeding. Little known; nest undescribed. Breeds during winter rains: males singing in late Nov through to Feb, female with brood patch in Feb, and recently fledged young observed in Feb and early Apr. Singing males are clustered, and pairs are often close together during breeding season, suggesting that breeding is semi-colonial.
Movements. Resident, with some movement to lower elevations outside the breeding season.
Status and Conservation. VULNERABLE. Restricted-range species: present in Socotra EBA. Rare and local. Considered at risk because of its tiny global range (c. 310 km²), low density and patchy distribution within its range. Total population estimated to be 1400 birds (c. 300 pairs) and thought to be stable, but may face threats from increasing grazing pressure and introduced alien predators, including feral cats, black rats (*Rattus rattus*) and small Indian civets (*Viverricula indica*).
Bibliography. Anon. (2010c), Butchart & Stattersfield (2004), Byers, Olsson & Curson (1995), Clouet *et al.* (1998), Collar *et al.* (1994), Fry & Keith (2004), Jennings (2010), Kirwan *et al.* (1996), Morton (1996), Ogilvie-Grant & Forbes (1903), Porter & Suleiman (2011), Ripley & Bond (1966), Ryan *et al.* (2009), Stattersfield & Capper (2000).



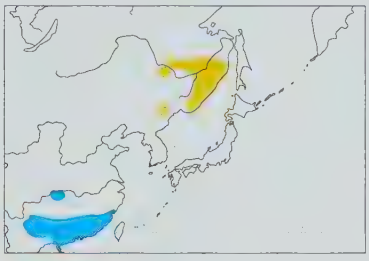
27. Cape Bunting

Emberiza capensis

French: Bruant du Cap **German**: Kapammer **Spanish**: Escribano de El Cabo
Other common names: Southern Rock Bunting; Vincent's Bunting (*vincenti*)

Taxonomy. *Emberiza capensis* Linnaeus, 1766, Cape of Good Hope, South Africa.
Distinctive NE race *vincenti* sometimes treated as a separate species. Considerable geographical variation in plumage tone, but validity of large number of subspecies questionable; proposed race *media* (described from Deelfontein, in Northern Cape) is synonymized with *cinnamomea*. Eleven subspecies recognized.
Subspecies and Distribution.
E. c. nebularum (Rudebeck, 1958) – SW Angola.
E. c. bradfieldi (Roberts, 1928) – N & C Namibia.
E. c. capensis Linnaeus, 1766 – S Namibia S to SW South Africa (Western Cape).
E. c. vinacea Clancey, 1963 – NE Northern Cape (South Africa).
E. c. cinnamomea (M. H. C. Lichtenstein, 1842) – S Northern Cape and Eastern Cape E to W Free State (South Africa).

E. c. vincenti (P. R. Lowe, 1932) – locally in highlands of SE Zambia, S Malawi, adjacent Mozambique and extreme SW Tanzania.
E. c. plowesi (Vincent, 1950) – NE Botswana and Zimbabwe (E to Nyange, in E highlands).
E. c. smithersii (Plowes, 1951) – Chimanimani Mts, in E Zimbabwe and adjacent Mozambique.
E. c. limpopoensis (Roberts, 1924) – SE Botswana and adjacent South Africa (North West and Limpopo Provinces).
E. c. basutoensis (Vincent, 1950) – breeds Lesotho highlands and adjacent E South Africa (W KwaZulu-Natal); post-breeding movement to lower elevations.
E. c. reidi (Shelley, 1902) – lowlands of Lesotho and E Free State E to W Swaziland and interior of KwaZulu-Natal.



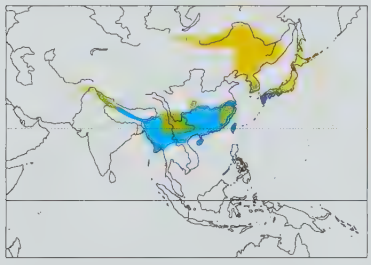
Descriptive notes. 15–16 cm; 17–27 g. Male nominate race has head striped black and white, with narrow white median crownstripe; mantle and back grey-brown with prominent dark streaking, merging into plainer rump; upperwing-coverts rich chestnut (forming distinct shoulder patch), greater coverts with blackish-brown inner webs; flight-feathers blackish-brown with rufous outer margins; throat off-white, underparts pale grey, undertail-coverts whitish; iris dark brown; bill dark grey, paler lower mandible; legs dark grey to pinkish-grey. Female is slightly smaller than male, very similar in plumage, but may appear duller with brown tinge in head stripes (often indistinguishable in the field). Juvenile is similar to female, sometimes with diffuse streaking on breast. Race *nebularum* is palest, whitish below and rather plain sand-grey above; *bradfieldi* is slightly richer in tone than previous; *cinnamomea* is richer above than nominate, washed yellow-buff below; *vinacea* is paler than nominate, with redder upperparts and buff-washed underparts; *reidi* has warmer colouring than nominate, with pale areas of head tinged rich buff, underparts washed cinnamon; *basutoensis* is darker and greyer than most other races, with heavy streaking above and a grey-washed throat; *limpopoensis* is even richer above than *reidi*, with extensive rufous in wing; *plowesi* is pale, with pale grey underparts and buff-washed upperparts, recalling *bradfieldi* but more heavily streaked above; *smithersii* is dark olive-grey above, heavily streaked, and darker olive-grey below than *basutoensis*; *vincenti* is the most distinctive, has upperparts dark grey, chestnut shoulder largely confined to lesser and median upperwing-coverts, greater coverts blackish, edged chestnut, throat whitish, underparts dark slate-grey with almost blackish belly. Voice. Male song an accelerating series of cheerful notes, "chip chup chip chup chit-it wit-wee", often repeated monotonously from elevated perch. Typical call, by both sexes, a nasal "wer-wi-wer" or "wee-ti-pee-yer", ascending in pitch.
Habitat. Shrubland and grassland, usually in rocky areas. Favours dry habitats and well-drained areas in more mesic habitats where there are openings on ground between vegetation. Visits gardens close to natural vegetation.
Food and Feeding. Diet includes grass and forb seeds, soft green leaves, fallen fruits, arils of *Acacia cyclops*, and wide diversity of invertebrates, including termites (Isoptera), hairless caterpillars, grasshoppers (Orthoptera), moths (Lepidoptera), ants (Formicidae), spiders (Araneae) and larvae of beetles (Coleoptera), flies (Diptera) and wasps (Vespidae). Forages mainly on ground, hopping in open areas among vegetation. Also takes some seeds from low plants, and scavenges among detritus heaps at harvester ant (*Messor capensis*) nests. Occurs singly and in pairs. Can become tame and confiding, entering buildings and scavenging scraps at picnic sites. Visits water to drink in more arid areas, and bathes frequently in warm weather.
Breeding. Season May–Jan (mainly Sep–Oct) in winter-rainfall area of Western Cape; elsewhere Oct–Jun (peak Nov–Jan in most areas, Apr–May in Malawi). Monogamous. Nests solitarily. Male displays by singing from prominent perch, as well as in aerial display with slow, deep wingbeats. Nest built by female, often accompanied by male, a neat cup of grass, plant stems and roots, lined with finer material, sometimes including animal hair, placed on ground near rock, at base of grass tuft or in sheltered spot on hillside, or low down in bush. Clutch 2–5 eggs (usually 2–3), white or washed greenish-blue, with blackish and brown markings; incubation period 13–14 days; chicks fed by both sexes, nestling period 10–13 days in wild, up to 18 days in captivity.
Movements. Largely resident; subject to local influxes in some areas. In highlands of Lesotho, race *basutoensis* descends in winter to lower elevations in adjacent South Africa (KwaZulu-Natal and Eastern Cape), but is resident in alpine belt of KwaZulu-Natal.
Status and Conservation. Not globally threatened. Fairly common to common throughout much of its range; generally scarce in extreme NE, where absent from much seemingly suitable habitat. Density in fynbos 8–15 birds/km². Persists in recently isolated habitat islands, suggesting that it is tolerant of habitat fragmentation, and inhabits fynbos areas invaded by *Acacia cyclops*.
Bibliography. Armani (1985), Benson (1941, 1982), Benson & Benson (1977), Brickell & Arnold (1990), Brickell & Konigkramer (1997), Brown & Barnes (1984), Byers, Olsson & Curson (1995), Dean (1997, 2000), Dean & Bond (1994), Dean & Milton (2001), Fraser & Crowe (1990), Friedmann & Northern (1975), Fry & Keith (2004), Harrison *et al.* (1997), Hockey *et al.* (2005), Irwin (1981), Johnson (1998), Kieser & Kieser (1978), Medland (1996), Oatley (2005), Rudebeck (1958), Skead, C.J. (1995), Skead, D.M. (1960, 1966a, 1966b), Tarboton (2001), Vincent, A.W. (1949), Vincent, J. (1936), Winterbottom (1970), Woodall (1971).

28. Tristram's Bunting

Emberiza tristrami

French: Bruant de Tristram **German**: Tristramammer **Spanish**: Escribano de Tristram

Taxonomy. *Emberiza tristrami* Swinhoe, 1870, Amoy [= Hsiamen], Fujian, China.
Sometimes placed in a separate genus, *Ocyris*. Recent phylogenetic study suggests that this species may form part of a clade with *E. chrysophrys*, with *E. variabilis* as sister-species. Monotypic.
Distribution. Breeds NE China (from Lesser Khingan Mts and R Zeja, in Heilongjiang) E to SE Russian Far East (Amurland and Ussuri regions, including Sikhote Alin Mts). Winters in SE China (SE Yunnan E to Fujian, also Hunan and E Sichuan); very rare winter visitor also N Thailand and N Laos, probably also N Vietnam (Tonkin).
Descriptive notes. 15 cm; 14–21 g. Distinctive, small and compact bunting with striped head. Male is unmistakable, has black head and throat with white central crownstripe, broad white supercilium (tends to be buffish in front of eye) extending a little behind ear-coverts, white spot on upper rear corner of ear-coverts, sharp white submoustachial stripe extending back to side of neck; hindneck and mantle dull buffy brown with diffuse black streaking, becoming rufous-brown to chestnut on lower back, unstreaked rump and uppertail-coverts; tail brown, central feather pair rufous-brown, outer two pairs with some white at edges; median and greater upperwing-coverts with buff to whitish tips (two distinct wingbars), rufous edges of primaries forming patch on folded wing; underparts



white, extensive rufous-brown wash with some dark streaking on breast and flanks; iris dark chestnut-brown; bill rather pointed, grey above and at tip, pinkish lower mandible; legs light fleshy-pink with whitish claws. Female is duller than male, less contrasting, with dark parts of head greyish-brown (instead of black), but same pattern of stripes, buff supercilium and ear-coverts, with buffish-white chin and throat, dark malar stripe. In fresh non-breeding plumage in autumn, buffish fringes makes white parts buffier and black parts browner, and partly concealing dark colour of throat. Juvenile resembles female, but somewhat duller; first-winter male similar to male non-breeding, but lores and ear-coverts noticeably browner with contrasting dark border, iris dark grey-brown; first-winter female generally very similar to non-breeding female, but crownstripe, supercilium and submoustachial stripe more buffish. Voice. Song, from inconspicuous perch in tree, a high-pitched unit followed by a drawn-out one, one or two units given 1–4 times in rapid succession, often with final "chit", one such phrase could be "hsiee swee-swee swee-tsirririri"; rather similar to song of *E. chrysophrys*. Call an explosive "tzick", irregularly repeated.
Habitat. Forested areas with good presence of undergrowth bushes, especially on hills, in Ussuriland also occupying flat areas. Seems to prefer mixed forests, but found also in understorey of conifers, in tall pine (*Pinus*) forests as well in spruce (*Picea*) in taiga. In winter in forest in wooded hills.
Food and Feeding. Diet consists of both vegetable and animal matter. During migration recorded as taking beetles (Coleoptera), flies (Diptera) and other insects, as well as seeds. Forages on ground. In small flocks outside breeding season.
Breeding. Laying at end of May or beginning of Jun; two broods in a season. Nest made from dry grass blades, often lined with horsehair, built near ground, often among grasses or on lower branches of bush; in one study, important factor for nest-site selection was presence of herbs and bushes, with 80% of nests built in false spiraea (*Sorbaria sorbifolia*); second nests found 50–120 m from first ones. Clutch 4–5 eggs, pinkish with greenish tinge, marked with sparse blackish patches and streaks; incubation entirely by female, period 12–14 days; no information on nestling period; starts to build nest for second brood 1–1·5 weeks after fledging of first brood. Average success 3·7 fledglings.
Movements. Autumn migration starts in Sept, most having departed from breeding areas during Oct, with last stragglers recorded Dec. Main passage during Sept in Korea, and Oct in Beidaihe (NE China). Normally stays in winter quarters Nov–Mar. Main spring passage in NE China and Korea between end of Apr and beginning of Jun; arrival on breeding grounds in Ussuriland from end Apr to beginning May, when snow still lying. Regular on passage in E Mongolia. Annual in autumn and spring passage on islands in Sea of Japan and Korea Strait; regular in E Mongolia. Vagrant to main islands of Japan.
Status and Conservation. Not globally threatened. Common to fairly common locally in appropriate habitat over most of its breeding range; little evidence of any marked decreases in recent decades. Local study in Ussuriland (Kedrovaya Pad Reserve) revealed 18 pairs/km² as highest breeding density, in riparian mixed forest.
Bibliography. Alström *et al.* (2008), Armani (1985), Brazil (1991, 2009), Byers, Olsson & Curson (1995), Cheng Tsohsin (1987), Dementiev *et al.* (1954, 1970), Flint *et al.* (1984), Gamova (2002a), Ilinskii (1976, 1981), Kanouchi *et al.* (1998), Knystautas & Liutkus (1984), Knystautas & Sibnev (1987), Koblik *et al.* (2006), Kuleshovar (1970), MacKinnon & Phillipps (2000), Maki & Onishi (2000), Nam Hyun-Young *et al.* (2011), Rasmussen & Anderton (2005a, 2005b), Robson (2000).

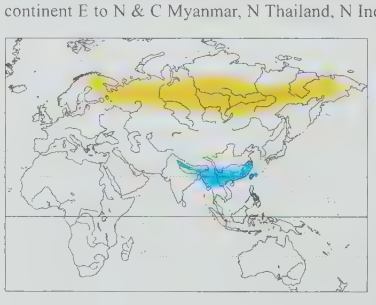
29. Chestnut-eared Bunting

Emberiza fucata

French: Bruant à oreillons **German**: Bandammer **Spanish**: Escribano Orejudo
Other common names: Grey-headed/Grey-hooded Bunting

Taxonomy. *Emberiza fucata* Pallas, 1776, at Onon and Ingoda Rivers, near Chilka, Chita, southeastern Siberia, Russia. Recent phylogenetic analyses indicating that this species is sister of *E. calandra* considered unreliable, and not well supported in different analytical approaches in same study. Proposed race *fluviatilis* (described from Zhenjiang, in Jiangsu, in E China) treated as synonymous with *kuatunensis*. Three subspecies recognized.
Subspecies and Distribution.
E. f. fucata Pallas, 1776 – breeds E Mongolia (including Khentii) and SE Transbaikalia E to SE Russia (Amurland, S Khabarovsk, S Ussuriland), NE China (Heilongjiang), Sakhalin I, Korea and Japan (S Kurils, and Hokkaido S to C Honshu); winters in S Japan (C Honshu S to Ryukyu Is), S Korea, S China, including Hainan, and Taiwan.
E. f. kuatunensis La Touche, 1925 – breeds E China (Zhejiang and Fujian); winters to SE China, Bangladesh, N & C Myanmar and N Indochina.
E. f. arcuata Sharpe, 1888 – breeds in Himalayas from N Pakistan E to W Nepal and S China (N Yunnan); winters lower in W Himalayas.

Descriptive notes. 16 cm; 14–21 g. Medium-sized bunting, adult with distinctive facial pattern and double breastband. Male nominate race breeding (worn plumage) has dark-streaked grey crown and nape, bright chestnut ear-coverts, prominent white eyering, narrow black moustachial stripe, white submoustachial stripe, chin and throat, and black malar stripe, malar expanding on breast side and breaking up into black streaks and spots that extend as broad necklace across breast; mantle and upper back grey-brown with black streaking, scapulars, lower back, rump and uppertail-coverts rufous-brown, feathers with dark centres; tail blackish-brown, rectrices with narrow pointed tips, long narrow white wedge on outer pair, small white spot on tip of next pair; upperwing blackish-brown, primaries with brown fringes; black necklace bordered below by white breastband, rest of underparts whitish, chestnut band on side of lower breast (sometimes forming complete band), warm orange-brown wash on sides gradually fading on belly, flanks narrowly streaked dark; iris dark reddish-brown; bill blackish above, lower mandible blue-grey to pale pinkish-horn; legs pinkish. Male non-breeding (fresh plumage) is similar to breeding, but head and breast patterns slightly obscured by pale feather fringes. Female has pattern like that of male, including breastbands, but with duller tones and less well marked, and



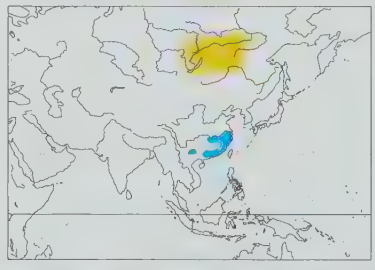
when fresh, with buffier tones. Juvenile has dull brown ear-coverts heavily edged dark and with small pale spot on rear corner, upperparts plain brown and heavily streaked, rump, scapulars and shoulders duller chestnut than adult pattern, underparts buff, fine streaks on breast and sides, pale chestnut flanks; first-winter resembles non-breeding adult of respective sex, but with even duller tones, worn flight-feathers and pinker lower mandible. Races differ mainly in levels of colour saturation and amount of chestnut on breast: *kuatunensis* is slightly smaller than nominate, darker and more reddish on upperparts, breastband similar, about intermediate in coloration and size between nominate and next; *arcuata* is slighly smaller than nominate, darker above and below, with richer tones and more rufous on back and flanks, whiter throat, broader black gorget, less prominent wingbars, female has breastband more marked than on nominate. Voice. Song, from top of shrub or weed, is twittering and more rapid than that of sympatric buntings, starts with a few staccato "zwee" or "zip" notes, accelerates into variable twitter and ends in three-part phrase, "chip chip chil-ri-wit chi chi tsiririri" or "zip zizewüziwiziriri chüpee chürüpp", reminiscent of song of *E. cioides*, but shorter and weaker; can be given also at slower tempo, with different units more clearly discernible, "zip chup chup cheechewee (tziri)". Call an explosive "pzick", similar to that of *E. rustica*.
Habitat. Scrubby hillsides, open areas near marshy fields and wetland fringes, rich floodplain meadows with bushes, and open grassy areas with thickets; in winter also in cultivated areas, including rice stubbles, and scrubby grassy fields. Often seen in low bushes and tall grasses adjoining fields and marshes. Occurs also in young secondary growth.
Food and Feeding. Diet consists of grass seeds and some insects. Forages on ground. Usually singly or in small parties of up to five individuals. In non-breeding season sometimes in larger flocks; also joins mixed flocks with *E. rustica* and *E. variabilis* and Brambling (*Fringilla montifringilla*).
Breeding. Start of breeding May or early Jun, with late broods during Aug in N of range; two broods in a season. Nest built from dry grass blades, weed stems, rootlets and twigs, lined with animal hair, fine roots and grass, placed in depression on ground in dry patch of soil in marsh, well concealed inside vegetation, or among low branches in bush. Clutch 3–6 eggs, usually 4, glossy white to yellowish-white or pale greenish-grey with sparse brown marks or sometimes darker spots and fine lines; incubation period c. 12 days. No further information.
Movements. Migratory. N populations (nominate race) winter in S Korea, S Japan, Taiwan and S China, including Hainan, between Nov and Apr; spring migration in NE China during Apr–May. Migrants recorded at Beidaihe (NE China) in variable numbers, mainly in Sept–Oct and in Apr–May; maximum single-day count 2100 individuals (21st Sept), but such numbers exceptional. Populations from E China (*kuatunensis*) apparently winter in S parts of range, reaching NE Indian Subcontinent and E to N half of Myanmar, N Thailand, N Laos and N Vietnam. Himalayan populations (*arcuata*) make post-breeding descent to lower elevations in foothills and adjacent plains; one record from NW Afghanistan considered doubtful, requiring re-evaluation.
Status and Conservation. Not globally threatened. Widespread, but rather uncommon. Global population not quantified; believed to be stable, as no local declines or substantial threats reported. Overgrazing possibly a threat locally in Mongolia and China.
Bibliography. Alström *et al.* (2008), Armani (1985), Bibikov (1960), Busching (2002), Byers, Olsson & Curson (1995), Eda (1996), Flint (1979), Fu Tongsheng *et al.* (1998), Fujimaki (1989), Gao Wei (1983), Golub (1983), Hwang Bo-Yeon & Park Shi-Ryong (1996), Ilinskii (1981), Kanouchi *et al.* (1998), Kim Kil-Won & Park Shi-Ryong (1993), La Touche (1906), Li Dehao *et al.* (1978), MacKinnon & Phillipps (2000), Maki & Onishi (2000), Nakamura & Iijima (1977), Nishi (2004), Nishide (1987), Rasmussen & Anderton (2005a, 2005b), Robson (2000), Ryabitsev (1997), Shaw (2004, 2008), Slack (2009), Sodhi *et al.* (1999), Sokolov & Sokolov (1986, 1987), Sora (1976), Sung Ha-Cheol & Park Shi-Ryong (1994), Uemura (1989), Yamagishi *et al.* (1973).

30. Little Bunting

Emberiza pusilla

French: Bruant nain **German**: Zwergammer **Spanish**: Escribano Pigmeo

Taxonomy. *Emberiza pusilla* Pallas, 1776, Daurian Range, southern Chita, south-eastern Siberia, Russia.
Sometimes placed in a separate genus, *Ocyris*. Recent phylogenetic study suggests that this species is closely related to *E. rustica*, *E. aureola*, *E. rutila*, *E. sulphurata* and *E. spodocephala*, forming a subclade with them; it has been suggested that they form a polytomous group of species, probably the result of a rapid, "simultaneous" radiation. Monotypic.
Distribution. Breeds from NE Norway, N Sweden, NE Finland and N Russia E across Siberia and Russian Far East (N to mouth of Ob and Gydan Peninsula, to c. 75° on R Yenisey, and mouths of Indigirka, Kolyma and Anadyr) to Pacific, S to c. 60° N in W and to middle R Yenisey, N of L Baikal, S Yakutia and near R Arka on Okhotsk Sea coast. Winters in region from N Indian Subcontinent E to N & C Myanmar, N Thailand, N Indochina and S China (S of R Yangtze).



Descriptive notes. 12–13·5 cm; 12–19·3 g. Small bunting, c. 10% smaller than otherwise somewhat similar *E. schoeniclus*; small bill with straight culmen. In breeding plumage (worn) has much of head, including chin and upper throat, deep chestnut, prominent pale eyering, very dark broad lateral crownstripe, narrow dark line behind eye and around rear and lower edges of ear-coverts, latter with small light buff spot in rear corner; some variation, some individuals with less extensive chestnut, having rear supercilium and rear crown more creamy and chin buffish; upperparts greyish-buff, heavily streaked dark brown, rump less clearly streaked; lesser upperwing-coverts grey-brown, median and greater coverts dark brown with narrow pale tips (forming wingbars), flight-feathers dark brown with narrow pale reddish-brownish edges; tail brown, outermost feather with white outer web and white wedge on inner web, next feather with smaller pale wedge; lower throat and underparts whitish-buff, prominent streaks on breast and flanks; iris dark red-brown; bill dark grey, cutting edges and base of lower mandible pale pinkish-grey; legs pinkish. Non-breeding (fresh) plumage is similar, but head pattern somewhat obscured by paler feather fringes, has light red-brown lores and anterior supercilium, pale reddish-brown median crownstripe between dark crown sides, red-brown to orange-tinged yellow-brown ear-coverts with narrow dark border at rear and small pale spot in rear corner; upperparts with broader pale feather fringes than in breeding plumage, and underparts buffier, with whitish belly, and slightly more diffuse streaking. Sexes very similar. Juvenile is like adult, but plumage with less rich tones, supercilium sandy buff, ear-coverts rufescent brown, submoustachial stripe and throat pale sandy buff, nape olive-brown but less streaked than crown, mantle sandy buff with some rufous-brown and heavily streaked black, breast yellowish-buff and rather heavily streaked, iris dark grey-brown; first-winter much as adult winter. Voice. Song, from top of tree or bush, rather variable, consisting usually of two or three parts each of which composed of a number of similar units, with last part more variable, e.g. "zree zree zree tsütsütsütsü tzriiitu" or "tzrü tzrü tzrü zee zee zee zriiiiru"; some parts reminiscent of song of *E. schoeniclus*. Call a hard "pwick" or "zick", very like that of *E. rustica*, similar to call of Hawfinch (*Coccothraustes coccothraustes*) but weaker.
Habitat. Breeds in moist open taiga, or partly flooded forests, with dwarf birch (*Betula nana*) and willow (*Salix*) and alder (*Alnus*), as well as in more open tundra, from bushy areas to areas with only low, sparse shrubs; tends to concentrate along river valleys where willow stands present. Occupies less wooded and less flooded areas than those preferred by *E. rustica*, and wetter and less open areas than those used by *Calcarius lapponicus*. In winter uses variety of open and semi-open habitats, from edges of forest to scrubby hillsides, crop fields, stubble and paddyfields, also edges of roads and paths and areas of bushes near marshes; also visits gardens and orchards.
Food and Feeding. Diet during breeding includes seeds and invertebrates. Recorded items include mayflies (Ephemeroptera), stoneflies (Plecoptera), bugs (Hemiptera), adult and larval Lepidoptera, caddis flies (Trichoptera), adult and larval flies (Diptera), Hymenoptera, beetles (Coleoptera), spiders (Araneae), earthworms (Lumbricidae), also seeds of cowberry (*Vaccinium*), crowberry (*Empetrum*), grasses (Poaceae) and sedges (Cyperaceae). Nestlings fed mostly with invertebrates; fledglings fed mainly with defoliating caterpillars, craneflies (Tipulidae), midges (Diptera), beetles and spiders. Diet during winter mostly seeds, such as those of sedges, grasses and cereals, but invertebrates still form a significant percentage of items. Forages on ground and at low levels in bushes and trees. In N Scandinavia actively seeks caterpillars (of family Geometridae) a few metres above ground in birches, bilberry (*Vaccinium*) and other kinds of low vegetation. Solitary and in pairs and small groups. Outside breeding season usually in small flocks of up to a dozen or so individuals, occasionally more; mixes with other seed-eaters, also roosts with *E. schoeniclus*.
Breeding. Season begins relatively late, between early Jun and Jul, some pairs still nesting during Aug; single-brooded. Nest built entirely by female, composed of grass, twigs, stalks, moss and hair, lined with fine grass, lichens and hair, placed on ground and concealed in grass tussock, occasionally on tree stump or low down in tree. Clutch 4–6 eggs, colour variable from pale lavender-grey, pale ashy blue or pale green to pale pinkish-buff, pale chestnut or dark brown, with blotches of lilac-grey and marked with sparse dark reddish-brown spots, streaks and lines; incubation by both sexes, period 11–12 days; chicks fed by both sexes, leave nest 6–8 days after hatching, still unable to fly, fully fledged 3–5 days later; fed by both parents.
Movements. Migratory; winters mainly in region from NE Indian Subcontinent E to SE China and S to N Indochina. Normally migrates singly or in small loose flocks, very occasionally in flocks of 100 or more individuals. Autumn migration begins final third of Jul, increasing during Aug, most having left breeding areas by mid-Sept; those from W range initially head directly E, then turn SE in W Siberia; passage in Mongolia and N China during Sept and early Oct, and in NE China lasts a little longer, birds still passing during early Nov. During autumn regular in small numbers in NW Europe, Israel and Japan. Spring migration starts in Mar, last birds leaving wintering grounds early May; in NE China main period of spring migration between last third of Apr and first half of May. Vagrant in most W European countries, also Canary Is, N Africa, Turkey and Middle East, Afghanistan, Pakistan, Borneo, Philippines, W USA (Alaska and California) and NW Mexico (S Baja California); regular in some places, e.g. average of c. 30–35 each year in Britain, mainly Sept–Oct, and overwintering not uncommon.
Status and Conservation. Not globally threatened. Common to locally very common. One of the most numerous bird species in parts of the extreme N taiga. Estimated European population in range 5,000,000–8,000,000 breeding pairs, and considered secure. In favoured areas can reach very high densities, of more than 100 pairs/km². Annual fluctuations in occupation of some areas in C Siberia, with no pairs at all in some years and two years earlier 2 birds/km² or 48 birds/km² in preferred sites; in other study areas in Siberia dramatic fluctuations, between five and 30 breeding pairs in different years. Although no reliable estimates for Asian part of range, population assumed to be stable as no evidence of declines or potential threats. Reported decline in Finland during 1990–2000, however, and further estimates needed in order to determine whether similar pattern may emerge in European Russia and in E parts of global range.

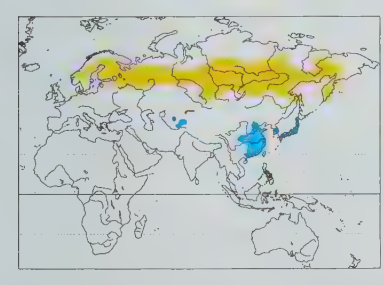
31. Yellow-browed Bunting

Emberiza chrysophrys

French: Bruant à sourcils jaunes **German**: Gelbbrauenammer **Spanish**: Escribano Cejigualdo

Taxonomy. *Emberiza chrysophrys* Pallas, 1776, Daurian Range, southern Chita, south-eastern Siberia, Russia.
Sometimes placed in a separate genus, *Ocyris*. Recent phylogenetic study suggests that this species may form part of a clade with *E. tristrami*, with *E. variabilis* as sister-species. Monotypic.
Distribution. Breeds in E Siberia from Irkutsk, R Nizhnyaya Tunguska and Bratsk E to R Vilyuy and Yakutsk, S to Chamar Daban range (S of L Baikal) and Stanovoy Mts. Winters in S & E China.

Descriptive notes. 13–15 cm; 15–24 g. Medium-sized bunting, similar in size to *E. rustica*, but with somewhat bigger head and stouter bill. Male breeding has striking head pattern, with bright yellow eyebrow starting just in front of eye and becoming white posteriorly, black crown with narrow white median crownstripe, and blackish lores, eyestripe and ear-coverts with distinct small white spot on rear ear-coverts; mantle grey-brown with blackish streaks, central mantle and scapulars rufous, rump chestnut; tail brown-black, rufous edges on central rectrices and white on outer ones; lesser upperwing-coverts grey, median coverts blackish with white tips (forming distinct wingbar), greater coverts with pale buff tips (less prominent wingbar), strong chestnut edges on tertials and inner secondaries; submoustachial stripe and throat white, prominent sharp blackish malar stripe; underparts white, blackish streaking on breast and flanks,



these also tinged pale rufous-brown; iris dark chestnut-brown; upper mandible dark grey, with pinkish along cutting edge, lower mandible pinkish-flesh, with dusky line running from tip along underside; legs pinkish-flesh. Female is broadly similar to male, but black areas on head partly concealed by brown fringes (fringes can wear away during breeding season, producing blackish pattern as on male), median crownstripe less pure white, tinged buffish, supercilium rather variable, from white to pale or deep yellow (independent of age), dark eyestripe extends down around rear ear-coverts, moustachial stripe ill-defined or lacking, malar stripe not so black and sharp as on male; chestnut stripe on centre of mantle slightly paler. Male and female non-breeding are both very similar to breeding female. Adult male and female non-breeding are rather similar, most cannot be sexed by plumage after complete moult in autumn. Juvenile is rather similar to female breeding, has lateral crownstripe dark brown, median crownstripe and supercilium pale buff or buff-white, side of neck and nape whitish with dark spots, lores buff, upper cheek and ear-coverts buff-brown, mantle tawny-buff and rump more rufous, all with distinct black streaks (more than on adult female breeding), lesser upperwing-coverts greyish-brown, streaking on breast narrow and more distinct than on adult; first-winter male similar to adult non-breeding, with rectrices more pointed, tail and wing feathers relatively more worn, some with streaked rump and uppertail-coverts, iris dark greyish-brown. Voice. Song, from perch in tree in dense forest, short, often starts with characteristic clear drawn-out note, usually followed by 2 high-pitched notes, and ends more rapidly, "chueee swii-swii chew chew chew" or "chueee tsriii tzriii wee-wee-wee tzitzi-tueei". Call a sharp "zick!", similar to that of *E. pusilla*, or "ziit", similar to that of *E. spodocephala*.
Habitat. In area of middle R Yenisey, inhabits open taiga on slopes of river valleys and on overgrowing vegetation, mainly where clusters of low conifers are regrowing and with rich ground cover; also mixed forest. In C Siberia favours well-drained mixed forests in region of Mirnoye, and in upper R Kamenka numerous in open mixed taiga with separate blocks of spruce (*Picea*) and fir (*Abies*) regrowth. Usually in clearings or edges of forest, but also interior of dense forest. In winter in scrubby and weedy areas, frequently near edges of forested areas.
Food and Feeding. Diet during breeding little known, presumably composed of an array of different flying insects and spiders (Araneae); these make up nestling diet. Outside breeding season diet dominated by seeds of grasses and herbs. Forages mostly on ground. During migration and in winter usually in mixed flocks with other buntings.
Breeding. Season begins late, usually during mid-Jun (some from beginning of Jun), dates of first clutches extending to mid-Jul, and recently fledged young recorded from beginning to third week of Jul. Nest messy-looking, with dry straw sometimes sticking out of sides of main section of cup, inner section made from fine straws, lined with finer straws and animal hair, mostly from horses (*Equus*) or moose (*Alces alces*), sometimes also moss, placed 1–2 m above ground and close to main trunk of bush or tree, normally conifer e.g. pine (*Pinus*) or spruce, exceptionally as much as 44 m up in tall tree. Clutch 3–5 eggs, greyish-white or cream-grey, with some lilac-grey shades, and irregular brown lines and dark streaks; incubation by both sexes, period 11–12 days; no information on nestling period.
Movements. Migratory; winters S & E China, accidentally S to Hong Kong. Breeding areas mostly deserted by mid-Aug, some late individuals present until mid-Sept; migration developing through Sept, when main passage noted NE China and Korea, reaching winter quarters in Nov–Dec. Main spring passage through NE China during Apr–May. Vagrants recorded W to Ukraine and W Europe (Britain, Netherlands, Belgium, France, Sweden).
Status and Conservation. Not globally threatened. Uncommon to rare in most of range; locally common in area of middle Yenisey. Reports of this species during breeding period in areas E of known range, such as in Magadan Oblast, may represent extreme limit of range or vagrancy. In middle Yenisey region found at higher densities in well-drained mixed forests in area of Mirnoye, up to 18 birds/km² (mean density in area 2 birds/km²); in another area, in upper R Kamenka, densities of 10–30 birds/km². No evidence of decline in population.
Bibliography. Alström *et al.* (2008), Brazil (1991, 2009), Byers, Olsson & Curson (1995), Cheng Tsohsin (1987), Cramp & Perrins (1994), Davydovich & Gorban (1990), Dementiev *et al.* (1954, 1970), Donnelly (1993), Elkins (1985), Flint *et al.* (1984), Glutz von Blotzheim & Bauer (1997), Holman (1990), Jiguet (2007), Kanouchi *et al.* (1998), Kapanen (1995), Kitson & Robertson (1983), Larionov & Germogenov (1980), Lewington *et al.* (1991), MacKinnon & Phillipps (2000), Maki & Onishi (2000), Nam Hyun-Young *et al.* (2011), Rogacheva (1992), Slack (2009), de Smet (1996), Snow & Perrins (1998), Svensson (1992), Svensson *et al.* (2009), Takano *et al.* (2001), Tebb & Ranner (2002), Ullman (2009), Vonk & van Ijzendoorn (1988), Wright (1994), Wunsch (1976).

32. Rustic Bunting

Emberiza rustica

French: Bruant rustique **German**: Waldammer **Spanish**: Escribano Rústico

Taxonomy. *Emberiza rustica* Pallas, 1776, Dauria = Transbaikalia.
Sometimes placed in a separate genus, *Ocyris*. Recent phylogenetic study suggests that this species is closely related to *E. aureola*, *E. pusilla*, *E. rutila*, *E. sulphurata* and *E. spodocephala*, all together forming a subclade. Geographical variation of present species weakly defined; sometimes treated as monotypic. Two subspecies currently recognized.
Subspecies and Distribution.
E. r. rustica Pallas, 1776 – breeds in C & N Fennoscandia E to EC Siberia (L Baikal); winters in C & E Asia.
E. r. latifascia Portenko, 1930 – breeds in E Siberia from L Baikal E to Anadyrland and Kamchatka, S to R Amur mouth and N Sakhalin I, possibly also in Greater Khingan Mts (NE China); winters in C & E Asia.

Descriptive notes. 13–14·5 cm; 15·5–24·3 g. Medium-sized bunting with indication of crest (erectile), and longish bill with straight culmen. Male nominate race breeding has black crown with distinct white spot on rear centre and hint of white median crownstripe, sharp white supercilium less well defined anteriorly and often starting just in front of eye, black lores and ear-coverts with distinct white spot on upper rear corner of ear-coverts, broad white submoustachial stripe continuing below lower edge of ear-coverts, poorly defined black malar stripe; nape and side of neck reddish, mantle and upperparts in general reddish-brown with black streaks; tail dark brown, two outermost feather pairs with white on inner webs; lesser upperwing-coverts reddish-brown, median and greater coverts dark brown with white tips (forming two distinct wingbars), tertials largely blackish on inner web and proximally on outer web, the central blackish area much narrower at mid-length of outer web, rest of outer web and rather broad tip reddish-brown with pale buff edging; primaries dark brown with pale edges, secondaries similar to primaries in pattern but with more rufous-brown edges; throat and underparts white, well-marked reddish breastband, variable reddish streaking on flanks; iris dark chestnut-brown; bill dark grey, pinkish-grey base of lower mandible; legs pinkish-flesh. Male non-breeding (fresh plumage) is similar in pattern, but black areas of head mostly concealed by brown feather fringes, and white areas of head, including supercilium, submoustachial stripe and throat, more buffish-tinged, lores and ear-coverts buffy brown. Female breeding is similar to breeding male, but colours duller, malar stripe more marked, and chestnut of breast and flanks tinged with dark brown; rump also more mottled and tips of median upperwing-coverts (wingbar) not so white as on male. First-winter male and female resemble non-breeding adult in pattern, only clear differences being duller iris colour and pointed shape of rectrices. Juvenile is similar to first-winter female, but breast more clearly streaked and iris dark grey-brown. Race *latifascia* differs from nominate only in having darker and more richly coloured plumage, with heavier streaks, purer black on crown, and bill on average larger. Voice. Song, usually from top of tree, consists of some melodious notes reminiscent of those of e.g. Garden Warbler (*Sylvia borin*), or parts of song of Dunnock (*Prunella modularis*), "duuu-dele-duudo-deluu-delu" or "dudeleu-dewee-deweea-weeu". Normal call a sharp "tzik", not unlike flight call of Song Thrush (*Turdus philomelos*), but often repeated several times at short intervals.
Habitat. Breeds in swampy lowland spruce (*Picea*) or pine (*Pinus*) forest with some birches (*Betula*), willows (*Salix*) or other deciduous trees, also scrub along riverbanks and around *Sphagnum* bogs; in flooded pine forests frequently found where pines stunted and dead trees covered with moss. Undergrowth usually present, usually consisting of horsetail (*Equisetum*) and bushes such as *Rubus*. In C Siberian taiga in boggy forest or sparse pine forest with undergrowth of *Alnaster*, *Ledum* and dwarf birches, and ground vegetation of sedges (*Carex*) and bog-moss (*Sphagnum*). Some reported differences between years according to mean temperature of spring: when spring cold apparently prefers open habitats, readily selecting burnt or other dry areas, and in years with warmer springs favours humid floodplains. In non-breeding season found also in dry lowland forest and woodland, riverine scrub, and various open areas, including rank vegetation at edges of agricultural land.
Food and Feeding. Diet during breeding season mostly seeds and invertebrates associated with swampy areas, e.g. damselflies and dragonflies (Odonata), stoneflies (Plecoptera), caddis flies (Trichoptera), flies (Diptera, including craneflies and mosquitoes), also any other available invertebrates e.g. beetles (Coleoptera), caterpillars and adult Lepidoptera, larval and adult Hymenoptera, spiders (Araneae), aphids (Aphidoidea) and grasshoppers (Orthoptera). Among plant items recorded as eaten are seeds of weeds and grasses (Poaceae), including several cereals e.g. barley (*Hordeum*) and oats (*Avena*), cloudberry (*Rubus chamaemorus*) and sedge; also seeds of conifers. Forages mostly on ground and in low vegetation. During winter especially in rice stubble, in reedbeds, and in open spaces of different kinds, including urban parks. Outside breeding season found in small groups, especially during migration; in winter often in bigger flocks, sometimes as many as 400 individuals.
Breeding. Season starts May or early Jun, e.g. in Finland average date of first egg 6th Jun, in Kamchatka nest-building through Jun; usually one brood, but two recorded in some places, such as St Petersburg region of extreme W Russia. Nest apparently built entirely by female, male observed to collect material (not yet confirmed whether he also helps with building work), composed of grasses, sedges, horsetail, mosses, lichens, leaves and conifer needles, lined with fine grasses and plant material, hair and sometimes feathers, placed normally on ground near water, hidden among grass tussocks, among thick roots, under bush or tree or overhanging grass, sedges or similar plants, sometimes up to 4·5 m above ground in tree or stump. Clutch 4–6 eggs, pale bluish-green to grey-green, greenish-blue or pale blue, densely covered with variable olive-brown or greyish spots, blotches and scrawls; incubation by both sexes, male (does not develop brood patch) tending to sit for shorter stints, period 11–13 days; chicks fed by both parents, leave nest at 7–10 days, before able to fly; young fed by both adults for further c. 15 days. In Finnish Lapland, c. 82% of laid eggs survived, from which 67% nestlings fledged, giving average of 55% of nests successful, with 1·7 fledged young per nest when failed attempts included, or 3·5 young per successful nest; recorded high annual variation in hatching success, from 20% to 68%, probably related to changes in weather during brooding stage.
Movements. Migratory. Winters mainly in Japan from S Hokkaido S to Kyushu (rarely farther S), Korea, and E China from Hebei and Shangdong S to Fujian and W to E Sichuan and S Shaanxi; small wintering population around Tien Shan in S Kazakhstan and NW China (W Xinjiang). Autumn migration begins early, from late Jul and Aug, and by mid-Sept breeding grounds in N part of range mostly vacated; W populations initially head E, following taiga habitats, until arrival in E Siberia, when they turn S, passing through E Mongolia; individual ringed in Sweden was recovered in NE China at L Songhua (Jilin). Departs from wintering grounds in China from Feb, passing through N China during Mar, with late migrants through Apr; in Japan leaves wintering areas during Apr; males usually arrive back on breeding grounds before females. Recorded as accidental in Svalbard, Iceland and many W European countries (regular in Britain), also in most Middle East countries, Egypt, Afghanistan, NW India, Nepal, and Hong Kong; in E Pacific recorded Alaska, SW Canada (British Columbia) and W USA (Washington, Oregon, California).
Status and Conservation. Not globally threatened. Common and widespread; locally abundant. Estimated European population (including European Russia) c. 6,100,000–10,000,000 pairs; no corresponding data for Asian part of range, but seems to be common. Recorded densities in Finland of 3·6 pairs/km² in peatlands, but only 0·9 pairs/km² in spruce forest and 2 pairs/km² in pine forest; in Sweden average 1 pair/km²; in European Russia up to 166 birds/km² recorded in pine forests in Vologda region and up to 167 pairs/km² in damp forests in St Petersburg region. Variable densities recorded in different areas of C Siberia, with average 8 birds/km², but in one year reaching maximum of 42 birds/km² on upper Yenisey floodplain near Fomka; in extreme E of range, highest densities in Kamchatka 190 pairs/km² in riverine woods of alder (*Alnus*) and willow. In late 19th and early 20th centuries, range in Fennoscandia expanded W & SW, presumably aided by creation of additional suitable habitat. Population trends in Europe have exhibited moderate decline since 1980, especially in Finland and Sweden during 1990–2000, with similar reports from Norway, mostly as a result of impact of human activities on damp forests. Forest management and modern silvicultural practices in N Finland have led to forest fragmentation, which was direct cause of declines in density in areas monitored before human intervention in virgin forests. No information on trends in E part of range, in Russia, but population in this area assumed to be stable, as no evidence of any declines.

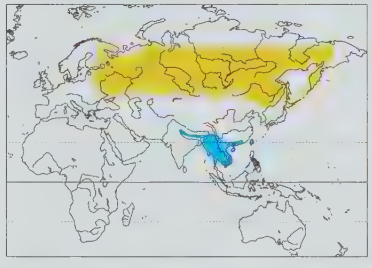
33. Yellow-throated Bunting

Emberiza elegans

French: Bruant élégant **German**: Gelbkehlammer **Spanish**: Escribano Elegante
Other common names: Elegant/Yellow-headed Bunting

Taxonomy. *Emberiza elegans* Temminck, 1836, Japan.
Sometimes placed in a separate genus, *Cristemberiza*. Recent phylogenetic analyses indicate that this is a sister-species of *Latoucheornis siemsseni*. Geographical variation not fully understood and complicated further because descriptions of some proposed races were based on individuals in passage; further study required. Proposed race *ticehursti* (described from Sidemi R, in S Ussuriland) included within nominate. Two subspecies currently recognized.
Subspecies and Distribution.
E. e. elegans Temminck, 1836 – breeds from Russian Far East and NE China to Korea and Tsushima I (SW Japan); winters mainly in Korea, S Japan and SE China.
E. e. elegantula Swinhoe, 1870 – breeds in C China (S Gansu and S Shaanxi S to Yunnan, Guizhou and Hunan); winter records S to NE Myanmar.



Descriptive notes. 15–16 cm; 14–22 g. Male nominate race breeding is unmistakable through combination of black crown with erectile crest, rich yellow supercilium (whitish at very front), black mask from lores and chin to rear ear-coverts, bright yellow throat, thin white band on foreneck, and sharply demarcated black crescent on breast; nape and side of neck grey (forming half-collar); feathers of mantle, scapulars and back rufous-brown with blackish shaft streaks and pale sandy brown fringes, rump and uppertail-coverts plain grey-brown; central rectrices brown, rest of tail feathers blackish-brown, outer pair with much white, adjacent pair with smaller white wedge; lesser upperwing-coverts grey, median and greater coverts with buff to whitish tips (forming two obvious wingbars), tertials blackish-brown with rusty-brown fringes and paler outer edge, primaries and secondaries brown with paler edges; underparts below breast mostly white, some chestnut streaks on flanks; iris dark chestnut-brown; bill blackish; legs pale grey-brown or pinkish. Male non-breeding (fresh plumage) has black pattern of head mostly concealed by brown feather fringes (gradually abraded during winter, revealing black during spring), nape brown, instead of grey, streaks on mantle less clear than during breeding; breast patch duller, with dark tones of centre of each feather concealed by brown fringes; bill paler blue-grey to dull pinkish-horn, typically dusky along culmen, tip and underside. Female breeding is similar to breeding male, but few contrasts in plumage, with crown and ear-coverts dark brown, supercilium buffish (more yellow on rear ear-coverts), throat yellow, but duller than on male, and never has black on chin; streaks on mantle less apparent; breast patch absent, breast has tinge of rufous-buff and indistinct rufous streaks. Female non-breeding is like non-breeding male, but dark areas of head browner. Juvenile has crown, ear-coverts and lores uniformly brown, supercilium pale buff, throat buffish-white, breast buffish-brown, breast and flanks finely streaked; first-winter male similar to adult non-breeding, but duller on head and breast, iris dark grey-brown; first-winter female similar to latter, but even duller. Race *elegantula* is darker overall and somewhat more richly coloured than nominate. Voice. Song, normally from perch in tree or bush, a long, monotonous twitter, e.g. "tswit tsu ri tu tswee witt tsuri weee dee tswit tsuri tu", often repeated at only brief intervals, at times seeming almost continuous; rather similar to song of *E. rustica*. Call a sharp "tzik", similar to that of *E. rustica*.
Habitat. Inhabits open dry deciduous forest and mixed deciduous–conifer forest, thickets and bushes, at edges and in clearings of woodland, often near streams; often on grassy slopes, also in hills and on sides of ridges, sometimes in young secondary pine (*Pinus*) and cedar forests with brush on low hillsides. In winter typically occupies mixed woodlands, shady conifer forests and edges of forests, orchards, and vegetation along riverbanks; also found in cultivated areas with scattered trees.
Food and Feeding. Food during breeding season consists mainly of invertebrates, but also some seeds. Forages on ground. Outside breeding season generally in rather small flocks, typically of up to c. 25 individuals, but up to at least 150; flocks average much larger during migration than in winter.
Breeding. Season begins in May; usually two broods. Nest a simple structure of loosely packed moss, plant stems, sedge and leaves, sometimes with hair, located in depression on ground under shrub or bush, sometimes openly. Clutch 4–6 eggs, whitish with background of lilac-grey tone, with irregular small dark spots and some irregular fine streaks; incubation by female, period 12–14 days. No other information.
Movements. Poorly known. Nominate race present in wintering areas from Nov to early Apr; winters mainly in Korea, S Japan and SE China (Guangdong, Fujian); apparently on rare occasions as far as Sakhalin I, Kuril Is, Hokkaido, Izu Is, Ryukyu Archipelago and Taiwan; uncommon passage migrant in E Mongolia. Race *elegantula* partly resident, but probably moving mostly to lower altitudes, with some N birds migrating to S part of breeding range; regularly reaches mountains of NE Myanmar. Species recorded as a vagrant in Alaska; records from Europe (Finland, Denmark, Netherlands, France and Germany) probably involve escaped cagebirds, rather than genuine natural arrivals.
Status and Conservation. Not globally threatened. Fairly common to locally common. Global population has not been reliably quantified, but assumed to be stable.

34. Yellow-breasted Bunting

Emberiza aureola

French: Bruant auréole **German**: Weidenammer **Spanish**: Escribano Aureolado
Other common names: White-shouldered/Golden Bunting

Taxonomy. *Emberiza aureola* Pallas, 1773, Irtysh River, south-central Siberia, Russia.
Sometimes placed in a separate genus, *Ocyris*. Recent phylogenetic study suggests that this species is closely related to *E. pusilla*, *E. rustica*, *E. rutila*, *E. sulphurata* and *E. spodocephala*, forming a subclade with them; it has been suggested that they form a polytomous group of species, probably the result of a rapid, "simultaneous" radiation. Two subspecies recognized.
Subspecies and Distribution.
E. a. aureola Pallas, 1773 – breeds E Finland and W Russia E to Kamchatka, S to N Ukraine, N Kazakhstan and W & C Mongolia; winters in S & SE Asia.
E. a. ornata Shulpin, 1928 – breeds E Transbaikalia and NE Mongolia E to NE China (Heilongjiang), Sea of Okhotsk coast, Sakhalin I, and N Japan and Kuril Is; winters in S China.

Descriptive notes. 14–15·5 cm; 14–33 g. Medium sized bunting, slightly larger than *E. rutila*, with longish bill; distinctive in most plumages. Male nominate race breeding has lower forehead, chin and upper throat back to ear-coverts black, upper forehead, crown, nape and upperparts deep rufous-brown, a few traces of pale fringes on nape, mantle and rump; tail dark brown, outermost rectrices with white on outer web; lesser upperwing-coverts dark grey with white lower row of feathers, median coverts white (white areas merging to form prominent white patch), greater coverts rufous-brown with white tips (less well-marked wingbar), tertials with deep rufous-brown outer webs, primaries and secondaries brown, narrowly edged pale; lower throat yellow, this extending as band across lower side of neck, contrasting narrow red-brown breastband; rest of underparts yellow, flanks with heavy blackish streaks; iris dark chestnut-brown; upper mandible dark grey, cutting edges and lower mandible pink; legs pinkish to dull fleshy-brown. Male non-breeding is very similar to breeding, but with pale fringes on head, buffish lores, supercilium and centre of ear-coverts, fringes on upperparts broader, and chin, throat and malar region yellow; breastband obscured by buffish fringes. Female breeding is rather similar to first-winter male, but with worn and bleached plumage; upper wingbar (on median coverts) narrower and lower wingbar (greater coverts) whiter, and breastband usually absent; some females extremely similar to first-summer male; iris dark chestnut-brown. Female non-breeding has upperparts similar to first-winter male, but tones warmer brown. Juvenile is broadly similar to female breeding, but exhibiting very fresh plumage, breast prominently streaked, iris dark grey-brown; first-winter male like adult non-breeding plumage, but with less apparent rufous tones, lateral crownstripe and border around ear-coverts blacker and more prominent, nape rufescent greyish-brown with some streaks, mantle brown with blackish streaks (feathers lacking rufous-brown centres), back to uppertail-coverts greyish-brown with faintly dark streaks, breastband largely replaced by diffuse streaking, iris dark grey-brown; first-summer male similar to male breeding, but with some characters more like those of female; second-winter male intermediate between adult and first-winter, with head and breast patterns mostly like adult, but crown more greyish-brown; second-summer male very like adult, but more prominent streaks on mantle; first-winter female very similar to adult non-breeding, but paler below, iris dark grey-brown. Race *ornata* is very like nominate, but darker, and with yellow of underparts brighter and richer in tone, and tends to have more extensive black on forecrown. Voice. Song, usually from exposed perch on top of tree or bush, a series of usually 5–9 units arranged in 3–4 segments each with 2–3 units, e.g. "djuu-djuu weee-weee ziii-zi", or "dwee-di-dee wuuu cha-cha zreee", or "tru-tru tra tro-tro triih" and variations; reminiscent of song of *E. hortulana*, but with slower tempo and higher pitch. Call a sharp clicking "tsick".
Habitat. Breeds in bushy areas, deciduous scrub and copses, very often along watercourses, edges of lakes and wetlands, low-lying wet meadows with tall herbage and scattered trees such as willow (*Salix*) or birch (*Betula*); also in areas with secondary scrub or sparse shrubs and trees, burnt areas, and peat bogs and alpine meadows with scattered solitary spruces (*Picea*); in Siberia also in high-elevation tundra where vegetation provides singing perches and nesting sites. In E part of range, in Amurland, present in both dry and damp meadows with rich or sparse shrub undergrowth with some scattered trees, as well as sedge (*Carex*) and grass. In non-breeding season found in cultivations, farmland with hedgerows, rice fields, stubble fields, reedbeds, grasslands and arable land with scrub, also gardens.
Food and Feeding. During breeding season mostly invertebrates, at other times seeds and other plant material; vegetable items taken throughout year. Recorded invertebrates in diet are damselflies and dragonflies (Odonata), stoneflies (Plecoptera), grasshoppers and allies (Orthoptera), bugs (Hemiptera), adult and larval Lepidoptera, lacewings (Neuroptera), caddis flies (Trichoptera), adult and larval flies (Diptera), adult and larval Hymenoptera, beetles (Coleoptera), spiders (Araneae), snails (Pulmonata); vegetable material taken includes seeds and other parts of rose (*Rosa*), and grasses (Poaceae) including wheat (*Triticum*), rice (*Oryza*), *Sorghum*, bamboo (*Bambusa*) and *Milium*. Nestlings fed almost entirely with invertebrates. On arrival on breeding grounds in Russia, forages on low herbs and grass, taking insects and seeds, and frequently on bushes such as roses (*Rosa*), rarely on bare ground; also in larch trees (*Larix*). In Hokkaido (N Japan), in contrast, recorded as foraging mainly on ground in summer period. Outside breeding season forages in flocks, sometimes of hundreds of individuals; roosts communally, usually in bushes.
Breeding. Season normally starts from second half Jun to beginning Jul; one brood, rarely two. Nest built by female alone, taking 3–5 days, of dry grass and stalks, lined with soft pieces of grass, rootlets and sometimes hair, placed on ground in depression under tussock or roots, or slightly above ground in willow, shrub or other kind of well-covered vegetation, as a rule exposed from above; in sample of 37 nests studied in C Siberia, only three protected from above by small tree branch and six hidden by wisp of overhanging grass; territory usually 0·5–0·8 ha in C Siberia. Clutch 3–7 eggs, usually 4–5, greyish or greenish with olive or purplish-grey markings, and variable blotches and scrawls; incubation by both sexes, male doing less of the work (does not develop

On following pages: 35. Golden-breasted Bunting (*Emberiza flaviventris*); 36. Somali Bunting (*Emberiza poliopleura*); 37. Brown-rumped Bunting (*Emberiza affinis*); 38. Cabanis's Bunting (*Emberiza cabanisi*); 39. Chestnut Bunting (*Emberiza rutila*); 40. Tibetan Bunting (*Emberiza koslowi*); 41. Black-headed Bunting (*Emberiza melanocephala*); 42. Red-headed Bunting (*Emberiza bruniceps*).

brood patch), period 13–14 days; nestling period 11–14 days; young leave nest before able to fly, gain independence after a further 7–14 days. Breeding success variable: in Amur region 50% of eggs in sample of 40 nests produced fledged young, whereas in Yakutia 71% of eggs hatched, 24% lost through predation and 5% infertile; in Volga–Kama only 15% of nests successful, as 85% were deserted or failed owing to predation or because of disturbance by dogs and red foxes (*Vulpes vulpes*).

Movements. Migratory; winters from C & E Nepal, Bangladesh and NE India E to SE China (Guangdong) and Taiwan, S to N Malay Peninsula and SE Asia. Leaves breeding grounds early, and returns late. In W of range first departures end of Jul, with late records during late Aug to early Sept, and main direction seems to be E, as no evidence of passage in Kazakhstan except in NW, and many detected on migration in NE Altai and Mongolia during end Aug, when passage most intense, continuing to mid-Oct; in NE Russia (Yakutia and Kamchatka) most leave breeding areas in Aug, but those on Sakhalin I (race *ornata*) departs later (after moulting), vacating areas by middle and late Sept and, in S of island, some not until end of Oct, on average 6–9 weeks later than nominate; in NE China passage evident Aug–Oct, and in Japan present until late Sept, but many stop in Yangtze Valley (China) to moult, and in Hong-Kong passage Oct–Nov. Arrival in wintering areas in Nepal, India and Myanmar from as early as Oct, but in S of non-breeding range not until Nov. Spring migration during Apr–Jun, many/most still in wintering areas during May. Vagrants recorded W to W Europe (N to Iceland, W to Ireland, Britain, Spain), Turkey and much of Middle East, Egypt, Pakistan, Nicobar Is, Philippines, Borneo and Alaska.

Status and Conservation. VULNERABLE. Fairly common to locally abundant; declining. Estimated global population 120,000–1,000,000 mature individuals. Can attain high densities locally, e.g. 500 birds/km² in C Siberia during 1970s–1990s. In W of range, first colonized Finland during 1910–1920s, with second sustained wave of immigration from 1940s to 1960s, producing more stable population; began to decline in 1980s. Formerly one of the most numerous breeding passerines in much of Siberia, and still common in some regions, but (although no systematic surveys) severe declines noted in most breeding areas, and has disappeared from parts of its former range since 1990. Has not bred in Finland since mid-2000s, and Kazakhstan range has contracted N by 300 km since 1990; rapid decline recorded in Russia (in Moscow and Baikal regions), and severe declines recently noted also in Japan (Hokkaido) and Mongolia. No longer occurs in big numbers at migration watchpoints such as Beidaihe (NE China), and numbers at wintering sites throughout range have apparently declined rapidly over last 20 years. Main reasons for this bunting's decline thought to be hunting on wintering grounds, especially in China, and conversion of many areas of suitable habitat to agricultural use in same region. As numbers even on pristine breeding grounds have dropped very rapidly, primary cause probably excessive trapping at migration sites and, especially, wintering sites. Flocks roosting in reedbeds are flushed and then caught in mist-nets, cooked and sold as food (described as "sparrows" or "rice-birds"); this practice, previously restricted to small area of S China, has become more widespread, and hunters must now travel widely in order to find sufficient birds. More than 1,000,000 individuals killed annually and sold as "snacks", although the practice illegal in some areas. In addition, each year, in China, thousands of males are killed, stuffed and sold as mascots, their presence in the home being believed to bring happiness to the human occupants. Still in wintering areas, agricultural intensification, including shift to irrigated rice production and consequent loss of winter stubble, has reduced the amount and quality of habitat, and destruction of reedbeds has led to loss of many roost-sites. On breeding grounds, habitat quality has suffered in some areas of range; in particular, changes in flow pattern of rivers resulting from dam construction has caused drying-out of damp meadows, an important breeding habitat. Range-wide survey required in order to determine true extent of decline of this species.

35. Golden-breasted Bunting

Emberiza flaviventris

French: Bruant à poitrine dorée **German**: Gelbbauchammer **Spanish**: Escribano Pechidorado
Other common names: African Golden-breasted Bunting, Yellow-bellied Bunting, Yellow-breasted Bunting(!)

Taxonomy. *Emberiza flaviventris* Stephens, 1815, Cape of Good Hope, South Africa.
Forms a superspecies with *E. poliopleura*. Geographical limits between some races disputed; proposed races *kalaharica* (described from Tsotsoronga Pan, in NE Botswana) and *carychroa* (Langata Forest, in SC Kenya) here included within nominate. Designated type locality of species may well be in error, as there is no evidence that the species ever occurred this far W. Three subspecies currently recognized.

Subspecies and Distribution.
E. f. flavigaster Cretzschmar, 1828 – Sahel from Mauritania E to N Ethiopia and Eritrea.
E. f. flaviventris Stephens, 1815 – S Sudan S through SC & E Africa to Botswana and South Africa.
E. f. princeps Clancey & Winterbottom, 1960 – S Angola and Namibia.

Descriptive notes. 15–16 cm; 15–28·3 g. Distinctive, with head boldly striped black and white, and flanks and lower belly whitish. Male nominate race has head black (including small area in front of and above eye) with prominent white median crownstripe, broad white supercilium and white stripe from bill back across cheek to side of nape (stripes may be washed brown in fresh plumage); hindneck grey, merging into chestnut on mantle, where variably striped paler brown; lower back and rump plain grey; tail blackish-brown, white tips on outer feathers; lesser upperwing-coverts blue-grey, white median coverts and tips of greater coverts (forming two white bars), remainder of greater coverts and flight-feathers blackish-brown with paler outer margins; chin white, throat, breast and central belly golden-yellow, washed orange on breast; flanks, lower belly and vent whitish; iris dark brown; upper mandible dark grey, lower mandible pink with dusky tip; legs pinkish. Distinguished from *E. poliopleura* by rather plain (not pale-streaked) mantle, scapulars concolorous with mantle, less white in face, and richer golden-yellow underparts; from *E. affinis* by larger size, prominent white wingbars, broader black facial stripes and plain grey (not brownish) rump; from *E. cabanisi* by slightly smaller size, obvious white cheekstripe, whitish flanks and belly, and orange wash on breast. Female is like male, but duller, with head markings washed brown and breast less richly coloured. Juvenile is even duller than female, with diffuse streaks on faded buffy-yellow breast, and rump washed brown. Race *flavigaster* is paler than nominate, with narrower black facial stripes, no black in front of eye, and plain rufous mantle; *princeps* is on average larger and paler than nominate. Voice. Male song a repeated series of sweet, clear whistles, "wee-ty, wee-ty, wee-ty, wee", "swee-ter, swee-ter, swee-ter" or "swee, swee, swee, swee-ter", sometimes ending with short trill. Calls include rather harsh "chok-weerrr" and high-pitched "tsip, tsip, tsip", given also in flight.

Habitat. Acacia (*Acacia*) and broadleaf woodland and savanna with sparse grass layer, typically in drier habitats than those preferred by *E. cabanisi*. Occurs in gardens locally, and moves into recently burnt areas within hours of fire. Persists in drainage lines invaded by mesquite (*Prosopis*) in Kalahari.

Food and Feeding. Diet includes grass seeds, soft green leaves, flower buds, and wide diversity of insects, including termites (Isoptera), hairless caterpillars, ants (Formicidae), mantids (Mantidae), small grasshoppers (Orthoptera), moths (Lepidoptera), flies (Diptera), and beetle (Coleoptera) and wasp (Vespidae) larvae. Forages on the ground in open areas; also in canopy of bushes and small trees. Takes grass seeds directly from seedheads. Singly and in pairs; may form small flocks when not breeding. Frequently visits water to drink and bathe, especially in dry season; peak visiting time early morning, with smaller peak in early afternoon.

Breeding. Season Jun–Sept in W Africa and Sahel and Sept–Apr (mainly Oct–Dec) in S Africa; varies regionally, linked to rains, in E Africa; up to three broods in a season. Monogamous; often retains same mate for several years. Breeds singly. Territorial, but moderately tolerant of other birds entering territory. Displaying male sings from elevated perch with crest raised, wings drooped, tail fanned and often orange breast feathers fluffed out; courts female by offering food and nesting material. Nest built by female, a loose cup of grass and plant stems, lined with fine material, often including animal hair, placed 0·5–2 m up in fork of bush or small tree. Clutch 2–4 eggs in most of range, only 1–2 in Sahel; white to pale greenish-blue marked around large end with black and sepia lines and dark dots and specks; incubation by female only, fed at nest by male, period 12–13 days; chicks fed by both sexes, both remove faecal sacs when chicks small (but sacs allowed to accumulate on nest rim when chicks larger), nestling period 12–17 days; adults defend brood vigorously, males occasionally performing distraction displays to lure predators from nest; juveniles continue to be fed by parents after fledging. Nests occasionally parasitized by Diederik Cuckoo (*Chrysococcyx caprius*); also, one nest with egg of Jacobin Cuckoo (*Clamator jacobinus*), thought to be case of egg-dumping by cuckoo in absence of usual hosts during drought. Breeding success variable; of eight nests studied in Zimbabwe, all failed; some chicks killed by Common Fiscal (*Lanius collaris*).

Movements. Largely resident; some local fluctuations in abundance. Sometimes wanders in small flocks outside breeding season, and may move out of areas during drought. Atlas reporting rates suggest regular movement into N Botswana from farther S in mid-summer.

Status and Conservation. Not globally threatened. Locally common. Typically tends to be the most common of the yellow-breasted buntings in Africa. Average densities in Swaziland 13 birds/km² in acacia savanna and 12 birds/km² in broadleaf woodland; in N South Africa, average of 5 pairs/km² in acacia woodland and 3 pairs/km² in broadleaf woodland. Caught for cagebird trade in some countries.

Bibliography. Armani (1985), Bannerman (1953), Borrow & Demey (2001), Brickell & Arnold (1990), Brickell & Konigkramer (1997), Byers, Olsson & Curson (1995), Chapin (1954), Clancey (1986), Clancey & Winterbottom (1960), Dean (1987, 2000), Dean *et al.* (2002), Elgood *et al.* (1994), Friedmann & Northern (1975), Fry & Keith (2004), Harrison *et al.* (1997), Hockey *et al.* (2005), Irwin (1981), Jerrard (2005), Lawson & Edmonds (1983), Lewis & Pomeroy (1989), Monadjem (2001, 2002), Oatley (2005), Panagis & Stutterheim (1985), Skead, C.J. 36. Somali Bunting

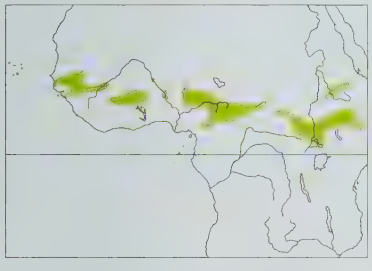
Emberiza poliopleura

French: Bruant de Somalie **German**: Somaliammer **Spanish**: Escribano Somalí
Other common names: Somali Golden-breasted Bunting

Taxonomy. *Fringillaria poliopleura* Salvadori, 1888, Soddè, Shewa, Ethiopia.
Forms a superspecies with *E. flaviventris*. Monotypic.

Distribution. Locally from Ethiopia and Somalia, also extreme SE Sudan and NE Uganda, S through Kenya to NE Tanzania.

Descriptive notes. 14–15 cm; 14–18 g. Male has head striped black and white, including prominent white median crownstripe (white stripes may be washed brown in fresh plumage); hindneck grey, mantle feathers chestnut with pale grey margins, appearing strongly streaked, scapulars with broad blackish centres then chestnut with narrow pale grey margins on outer webs, whitish-buff on inner webs; lower back and rump grey, back with diffuse blackish spots; tail blackish-brown, white tips on outer feathers; lesser upperwing-coverts grey, white median coverts and tips of greater coverts (forming two white bars on folded wing), remainder of greater coverts and flight-feathers blackish-brown with paler outer margins; throat, breast and central belly yellow, washed orange on central breast; flanks, lower belly and vent whitish; iris brown; upper mandible mostly dusky, with pink cutting edge, lower mandible pink; legs pale grey-brown. Differs from similar *E. flaviventris* in having strongly streaked mantle, scapulars largely blackish (not chestnut) contrasting with mantle, face whiter (no black in front of or above eye, and lateral crownstripes barely reach bill), slightly less white in tail, underparts paler. Female is duller than male, with brown wash on head. Juvenile is similar to female. Voice. Male song a series of 4–6 ringing whistles, "tswit, tsuwee tsuwee tsuwee", shorter and less variable than that of *E. flaviventris*.



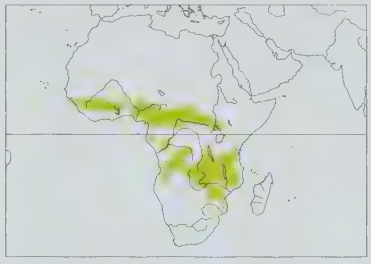
Habitat. Semi-arid and arid acacia (*Acacia*) scrub; to 2000 m in Ethiopian Rift Valley and to 1500 m in Somalia and N Kenya, but below 1200 m in C & S Kenya.

Food and Feeding. Diet mainly grass seeds; also some soft green leaves and insects, including termites (Isoptera), beetle larvae (Coleoptera) and moths (Lepidoptera). Forages mainly on ground. Often in small groups.
Breeding. Little known. Season mainly Apr–Jun (rarely Sept) in Ethiopia, Somalia and N Kenya, and Nov–Jan in S Kenya and Tanzania. Nest a cup of grass stems built in fork of bush. Clutch 2–3 eggs, white with grey-brown markings; incubation period in captivity 12 days; nestling period 16–18 days. No other information.
Movements. Presumably mostly resident. Occasionally attracted to lights at night in Kenya, and one extralimital record in NC Tanzania suggests some local movement.
Status and Conservation. Not globally threatened. Fairly common in most of fragmented range. Density 1 bird/ha in Tsavo East National Park, in Kenya.
Bibliography. Archer & Godman (1961), Armani (1985), Ash & Miskell (1998), Backhurst & Pearson (1977), Brickell & Konigkramer (1997), Byers, Olsson & Curson (1995), Fry & Keith (2004), Lack (1985), Lewis & Pomeroy (1989), Moreau & Moreau (1939).

37. Brown-rumped Bunting
Emberiza affinis

French: Bruant à ventre jaune **German**: Braunbürzelammer **Spanish**: Escribano Culipardo

Taxonomy. *Emberiza affinis* Heuglin, 1867, no locality = probably Dar Bertat, western Ethiopia. Four subspecies recognized.
Subspecies and Distribution.
E. a. nigeriae Bannerman & Bates, 1926 – Senegambia E to Nigeria and N Cameroon.
E. a. vulpecula Grote, 1921 – C Cameroon, S Chad and Central African Republic.
E. a. affinis Heuglin, 1867 – S Sudan, NE DRCongo, NW Uganda and (most likely this race) N Ethiopia.
E. a. omoensis Neumann, 1905 – S Ethiopia.

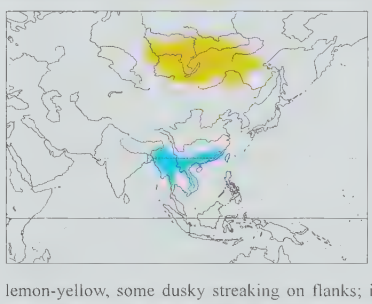


Descriptive notes. 13–15 cm; 14·5–18 g. A small bunting with rather slender bill, extensive white on face and extensively yellow below; lacks white wingbars of other African yellow-breasted buntings. Male nominate race has white head with black lateral crownstripe, black stripe extending from behind eye to back of ear-coverts, then continuing down to join up with slender black moustachial stripe; hindneck grey-brown, merging into chestnut on mantle and back, rump slightly paler, uppertail-coverts grey; tail blackish-brown, white tips on outer feathers; upperwing-coverts grey-brown with narrow pale margins, flight-feathers blackish-brown with narrow brown outer margins; chin whitish, throat and underparts yellow, washed rufous on breast, vent whitish; iris dark brown; upper mandible dusky grey, lower mandible paler greyish-blue; legs pale grey-brown. Female is slightly duller than male, white stripes on head with buff wash, dark stripe blackish-brown. Juvenile is duller than female, has brown lateral crownstripes streaked blackish, pale areas on face sandy brown, underparts dull buffy yellow. Race *vulpecula* is darker and plainer above than nominate; *omoensis* is dark brown above; *nigeriae* is paler, with grey-brown mantle streaked chestnut-brown, buff margins of greater upperwing-coverts forming pale wingbar in fresh plumage. Voice. Male song a short, buzzy trill lasting 1–1·5 seconds. Liquid contact call like that of a bulbul (Pycnonotidae) given from perch; short "chip" in flight.
Habitat. Mesic woodland, including riparian woodland fringe and locally around villages. Reportedly favours areas with large termitaria.
Food and Feeding. Diet of specimens from DRCongo contained insects, including termites (Isoptera); in captivity feeds on seeds of grasses and forbs, as well as beetle larvae (Coleoptera), crickets (Gryllidae) and spiders (Araneae). Forages on ground. Generally singly and in pairs.
Breeding. Little known. Only one nest reported, in Sudan in Mar; fledged chicks in Dec in Gambia. Nest not described; suspected as nesting in cavity in termitarium. In captivity, clutch 3–4 eggs, incubation period 12 days, nestling period 14–17 days. No other information.
Movements. Little known. Presumably mostly resident; most records in W Africa are in wet season, but this may simply reflect greater conspicuousness of males when breeding.
Status and Conservation. Not globally threatened. Generally local and scarce. May be locally common, with up to 8 males singing within 1 km.
Bibliography. Anon. (1995), Armani (1985), Bannerman (1953), Barlow *et al.* (1997), Borrow & Demey (2001), Brickell & Konigkramer (1997), Byers, Olsson & Curson (1995), Chapin (1954), Cheke & Walsh (1996), Elgood *et al.* (1994), Fry & Keith (2004), Grimes (1987), Lewis & Pomeroy (1989).

38. Cabanis's Bunting
Emberiza cabanisi

French: Bruant de Cabanis **German**: Cabanisammer **Spanish**: Escribano de Cabanis
Other common names: Cabanis's Yellow Bunting; Angola Bunting (*cognominata*); Three-streaked Bunting (*orientalis*)

Taxonomy. *Polymitra* (*Fringillaria*) *cabanisi* Reichenow, 1875, Cameroon.
Race *orientalis*, geographically separated from others, sometimes considered to represent a separate species; on other hand, *cognominata* sometimes synonymized with it. Three subspecies recognized.
Subspecies and Distribution.
E. c. cabanisi (Reichenow, 1875) – W Africa locally from Guinea and Sierra Leone E to Cameroon, Gabon, PRCongo, N DRCongo, S Sudan and NW Uganda.
E. c. cognominata (Grote, 1931) – C Africa from Gabon, PRCongo and Angola E to W Zimbabwe.
E. c. orientalis (Shelley, 1882) – Tanzania S to E Zimbabwe and Mozambique.
Descriptive notes. 16–17 cm; 18–27 g. A fairly large bunting with mostly dark head. Male nominate race has dark crown (little evidence of paler median stripe), white supercilium, and blackish ear-coverts and cheek contrasting with white throat; upperparts dark grey-brown, diffuse blackish streaks on mantle; tail blackish-brown, white tips on outer feathers; lesser upperwing-coverts dark grey-brown, median coverts and tips of greater coverts white (forming two white bars on folded wing), remainder of greater coverts and flight-feathers blackish-brown with paler outer margins; underparts yellow, sometimes tinged olive, with white undertail-coverts; iris dark brown; upper mandible blackish, lower mandible horn-coloured; legs horn-grey. Differs from other three African yellow-breasted buntings in dark side of head lacking white cheekstripe, grey (not chestnut-brown or brownish) mantle, lack of orange wash on breast. Female is duller than male, with brown-washed head and tawny wash on breast, wingbars less prominent (median coverts have blackish centres, and white tips of greater coverts reduced). Juvenile resembles a dull female, with brownish head, buff-washed supercilium and pale buff-yellow underparts. Race *orientalis* male has blacker head with more prominent pale median crownstripe (although still streaked blackish), mantle paler grey with more prominent streaking, yellow of breast extending onto throat, female more heavily streaked above, juvenile also has diffuse streaking on breast; *cognominata* is on average larger than previous, with rufous-washed crown and mantle. Voice. Male song varied, typically a repeated series of sweet, clear whistles, often reminiscent of that of *E. flaviventris*, but may also incorporate slow trills. Calls include ascending "burreee" and descending "tseeoo"; flight call "tsip".



Habitat. Broadleaf woodland and well-wooded savanna, including guinean savanna in W Africa and miombo (*Brachystegia*) woodland in C Africa. Often in rocky areas or open woodland with little or no understorey. Also locally in degraded scrub and along fringe of riparian forest.
Food and Feeding. Diet mainly insects, especially small grasshoppers (Orthoptera), and grass seeds; also other insects, including beetle larvae (Coleoptera). Forages on ground, singly and in pairs; sometimes joins mixed-species parties.
Breeding. Season Jul–Aug in W Africa and Sept–Mar (mainly Oct–Nov) in SC Africa. Monogamous. Solitary nester. Nest constructed by female, male occasionally delivers material, a loose, shallow cup of twigs, dry leaves and grass, lined with fine grasses and rootlets, built 1–5 m up in bush or small tree, usually well concealed among dense foliage. Clutch 2–3 eggs, white to pale green with grey-brown markings; incubation by female, fed at nest by male, period 12–14 days; nestling period 16 days. Nests occasionally parasitized by Klaas's Cuckoo (*Chrysococcyx klaas*).
Movements. Largely resident, subject to local movements in relation to drought. Listed as a summer visitor (Mar–Aug) at Ibadan, in Nigeria.
Status and Conservation. Not globally threatened. Scarce or uncommon through much of its range; locally common in some areas.
Bibliography. Anon. (1993), Armani (1985), Benson (1941), Borrow & Demey (2001), Brickell & Arnold (1990), Brickell & Konigkramer (1997), Byers, Olsson & Curson (1995), Chapin (1954), Cheke & Walsh (1996), Clancey (1965), Dean (2000), Elgood (1959), Elgood *et al.* (1994), Fry & Keith (2004), Grimes (1987), Harrison *et al.* (1997), Hockey *et al.* (2005), Irwin (1981), Skead (1960), Tarboton (2001), Vincent (1949).

39. Chestnut Bunting
Emberiza rutila

French: Bruant roux **German**: Rötelammer **Spanish**: Escribano Herrumbroso
Other common names: Ruddy Bunting

Taxonomy. *Emberiza rutila* Pallas, 1776, Onon River and towards the Mongolian border.
Sometimes placed in a separate genus, *Ocyris*. Recent phylogenetic study suggests that this species is closely related to *E. pusilla*, *E. rustica*, *E. aureola*, *E. sulphurata* and *E. spodocephala*, forming a subclade with them; it has been suggested that they form a polytomous group of species, probably the result of a rapid, "simultaneous" radiation. Proposed race *pamirensis* (described from Trans-Alai Range, in Pamir Mts) considered invalid, as based probably on vagrant birds. Monotypic.
Distribution. Breeds in C & E Siberia from Krasnoyarsk (N possibly to Podkamennaya Tunguska) E to S coast of Sea of Okhotsk, and S to L Baikal and Chita regions and NE China (Khingan Mts, in N Heilongjiang); probably also regularly in NE Mongolia (Khentii) and in Russian Far East (Sikhote Alin Range, in Ussuriland). Winters in Myanmar, S China, W Thailand, Laos and Vietnam.

Descriptive notes. 14–15 cm; 12–24 g. Medium-sized bunting with relatively short tail, longish bill and, in all plumages, yellow on underparts, unstreaked chestnut rump and almost no white on tail. Male breeding is distinctive, with head, breast and upperparts, including upperwing-coverts, uniformly chestnut, sharply demarcated from yellow of belly; tail feathers uniformly brown, small area of white at tip of outer rectrices; primaries and secondaries brown, narrow pale edges on primaries and chestnut edges on secondaries, tertials similar in colour to upperparts, but most of inner web brown; underparts below breast lemon-yellow, some dusky streaking on flanks; iris dark chestnut-brown; bill brown or bluish-horn, often paler bluish or dull pinkish-horn on most of lower mandible; legs typically pinkish, but variable. Male non-breeding (fresh plumage) is rather similar to breeding, with general chestnut colours concealed by pale fringes, especially on throat and superciliary area. Female breeding has crown greyish-brown, dark lateral crownstripe with some mixed chestnut, rather indistinct buff supercilium, rest of face dull buffish-brown, framed by brown postocular stripe which continues down and skirts ear-coverts to join narrow brown moustachial stripe, beneath which is pale buff submoustachial stripe, greyish to dusky brown malar stripe, and pale buff throat; nape greyish-brown with some indistinct streaks, mantle dark-streaked greyish-brown, back to uppertail-coverts plain rufous; lesser upperwing-coverts rufous-brown with some olive tinge, median and greater coverts with buffy tips (forming more distinct wingbars than in male plumages); breast and undertail-coverts often with some fine streaking, flanks with more prominent streaks; bare parts as on male. Female non-breeding is similar to breeding, but with upperparts and breast browner. Juvenile is in general similar to female non-breeding, but with more distinct streaks on crown and mantle, streaks on back and rump (absent in other plumages), breast buffish with prominent streaking, flanks, belly and undertail-coverts yellow, flanks with prominent black streaks; first-winter male similar to female non-breeding, but chestnut tones usually visible on crown, ear-coverts and/or breast, throat buffish without chestnut tones, mantle and scapulars olive grey-brown with brown streaks, lesser upperwing-coverts as on adult non-breeding, sometimes tinged olive, edges of median and greater coverts rather paler or buffish (but not forming visible wingbars); first-summer male similar to previous, but more evident chestnut tones on head and throat (paler fringes reduced by wear);

second-winter rather like male non-breeding, but with some features of first-winter, differs from adult in having broader fringes obscuring chestnut pattern of feather centres, buffish throat without chestnut base of feathers, wider pale tips on median and outer greater coverts (more obvious wingbars); presumed second-summer male similar to male breeding, but median coverts have dark bases and greater coverts dark centres, and both have wider pale tips (faint wingbar); first-winter female similar to adult, differing only in lack of rufous tones on lesser coverts, crown, mantle and scapulars. Voice. Song, from inconspicuous perch in tree, usually 3 slow pure notes followed by a characteristic thrilling, "tvia tvia tvia sre-sre-sre sisicha"; reminiscent of song of Pallas's Leaf-warbler (*Phylloscopus proregulus*) or of Olive-backed Pipit (*Anthus hodgsoni*); also somewhat similar to song of *E. spodocephala*, but more uniform and lower-pitched. Usual call "zick", similar to that of *E. pusilla*; also a thin high "teseep".

Habitat. Breeds in open forest with shrubby ground cover in S taiga, in coniferous forests of pine (*Pinus*) or larch (*Larix*), also in deciduous alder (*Alnus*) and birch (*Betula*), as well as in mixed forest, often on ridges of hills or slopes of mountains. In winter favours open forest, edges of woodlands and clearings, and cultivated land, from lowlands and foothills to 2500 m. During migration found also in grain fields, rice stubbles and bushes in cultivations, and open tall herb fields.

Food and Feeding. Diet during breeding season mainly invertebrates, such as caterpillars and other insects, as well as seeds; during migration and winter mostly seeds. Forages mainly on ground, flying up to branches of nearby trees when disturbed. Outside breeding season usually in small flocks.

Breeding. Season starts usually first half of Jun, very early after they arrive to the breeding territories. Nest built from grass blades, lined with thin rootlets, concealed on ground among shrubs. Clutch c. 4 eggs, white, tinged bluish, with brown streaks, black curls and some violet-brown streaks. No other information.

Movements. Migratory; winters in region from Myanmar E to SE China (Guangdong), S to W Thailand, Laos and Vietnam, less regularly in NE India (Manipur and N Cachar). Departure from breeding grounds mostly during Aug; speed of movement to S rather slow, since peak passage through Korea and NE China in Sept–Oct, although first migrants pass through this area earlier, and through lower Yangtze Valley during Oct–Nov, and in Hong Kong in Oct–Dec; scarce but regular migrant during Oct in Japan, where also some wintering records. Spring migration begins during Mar, with passage recorded in Hong Kong in Mar–Apr, and through E & NE China and Korea during Apr–May; arrives on breeding territories late May to early Jun. Vagrants recorded W to Tajikistan, Pakistan (Chitral), Ladakh, Nepal and Sikkim; also Europe (Norway, Finland, Britain Netherlands, Slovenia and Malta), where at least some records probably involve escaped cagebirds.

Status and Conservation. Not globally threatened. Common to locally fairly common. Global population not properly quantified, but species considered to be common during breeding season in S taiga and probably in most of its range. No evidence of any declines, and population considered stable, with no known imminent threats.

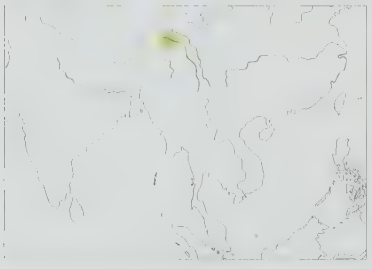
40. Tibetan Bunting



Emberiza koslowi

French: Bruant de Koslov **German**: Tibetammer **Spanish**: Escribano Tibetano
Other common names: Kozlov's/Koslow's Bunting

Taxonomy. *Emberiza koslowi* Bianchi, 1904, Dza Chu River, Lancang Jiang (Upper Mekong), east Xizang, China.

Affinities uncertain, perhaps a distant relative of *E. cioides*; has been thought to be closer to *E. leucocephalos* than to *E. rutila* or *E. melanocephala*. Monotypic.

Distribution. Upper reaches of R Lancang Jiang (Mekong), R Nu Jiang (Salween) and R Chang Jiang (Yangtze) in small area of NE Tibetan Plateau around Xizang–S Qinghai border of China.

Descriptive notes. 16 cm; c. 25 g. Distinctive stocky, rather bull-necked and relatively long-tailed bunting with prominent long supercilium. Male breeding has black crown bordered by wide white supercilia which narrowly meet on upper nape; lores and cheek to chin reddish-brown, ear-coverts black; nape greyish-brown, mantle and scapulars unmarked bright reddish-chestnut, back, rump and uppertail-coverts grey, washed olive; lesser and median upperwing-coverts grey, greater coverts and tertials reddish-chestnut, tertials with blackish centres; secondaries and primaries brownish-black; tail dark brown, central feather pair lighter, two outermost pairs with extensive white; throat, rear malar region and chest pure white, bordered below by black breastband, lower underparts grey, paling to whitish vent and undertail-coverts, latter with variable pinkish tinge; iris dark brown; bill blue-black; legs clear orange-yellow, toes darker. Male non-breeding is duller, with grey tips on feathers of crown and ear-coverts and dark mottling on rear supercilia and side of throat; breastband with greyish tipping, extending as weak streaking along flanks (most marked on rear flanks); upperparts weakly streaked to variable extent, with dark streaking on scapulars, rump and uppertail-coverts, but dull brown mantle streaked buff; lower mandible pale with dark tip. Female breeding has crown, nape, ear-coverts and side of neck olive-grey to reddish-grey, crown and nape finely streaked dark brown or reddish, darkish grey ear-coverts dulled by inconspicuous fine pale streaking, buff supercilium quite prominent, highlighted above by dark line along side of crown; lores to below eye pale yellowish-brown; mantle brownish-grey, streaked with black and variable amounts of chestnut, scapulars chestnut with dark shaft streaks, back, rump and uppertail-coverts light grey with olive wash; upperwing-coverts dark grey, medians with white tips (white wingbar), greaters with rufous edges and white tips, tertials blackish with rusty edges, flight-feathers brownish-black and narrowly edged buff; tail as on male; throat and upper breast whitish, washed light buff, with diffuse dark markings (forming inconspicuous malar stripe), weak collar of dark spots and streaks across upper breast separating pale grey of lower underparts from whitish throat; undertail-coverts light cinnamon-rufous; upper mandible grey, lower mandible paler. Non-breeding female in fresh plumage undescribed. Juvenile undescribed; first-winter male (worn late-winter plumage) similar to adult breeding, but duller above, mantle having broad buffy feather fringes, back, rump and uppertail-coverts greyish with strong olive wash, throat often with light buff wash, dark breastband obscured by greyish tips, merging with greyish-olive of lower underparts, paling towards vent, undertail-coverts pale yellow. Voice. Song, from stunted bushtop or boulder, an uncomplicated little phrase, has been transcribed as a twittering "tisp tsi tsi chiriree teetew", sometimes first note a little lower in pitch and phrase terminates in quiet jumble of notes, e.g. "chep chip chip chiriree chip-chee chuee tsi"; in general very similar to song of *E. godlewskii*. Two calls reported: one a drawn-out thin "seeee" (possibly as alarm, or a contact note given by foraging birds on ground); flight call a weak "tsip tsip".

Habitat. Relatively barren, steep scrubby slopes above tree-line. Favours mixture of dwarf alpine shrubs, notably cotoneaster (*Cotoneaster*), juniper (*Juniperus*), barberry (*Berberis*), *Ribes*, *Rosa* and *Cistus*, at foot of steep cliffs in areas of alpine grassland where seasonal grazing by yaks (*Bos grunniens*) can be heavy. Between 3600 m and 4600 m; marginal range overlap with *E. godlewskii*, but generally at higher elevations than latter.

Food and Feeding. Little information. Diet presumably various seeds, but in breeding season no doubt primarily insectivorous. Following prey items identified as brought to the one studied nest: several flies (Diptera), including a cranefly (Tipulidae), various small caterpillars and a small butterfly/moth (Lepidoptera), and a grasshopper (Orthoptera). Forages almost entirely on ground. Typically encountered in pairs or family parties; small flocks reported in winter.

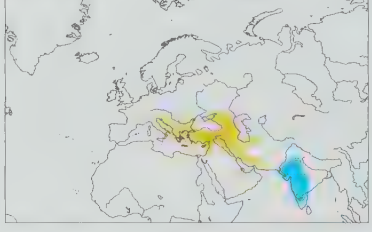
Breeding. Virtually undocumented. Breeding thought not to commence until very end of Jun or early Jul. Following details based on one studied nest. Nest was composed of grass and herb stems up to 2 mm in diameter, cup lined with finer grasses, placed at ground level in small spiny *Astragalus* shrub (c. 20 cm tall), afforded some extra protection by nearby willow (*Salix*) clump c. 1 m in height; nest domed (unique among buntings), with roof of dome interwoven within twigs of the *Astragalus*. Nest held three nestlings c. 12 days old on 28th Jul; both parents fed young, majority of the 21 visits during 3·5-hour observation period by male, parents flew 200–300 m from nest to foraging areas, returning very cautiously, dropping to ground and walking to nest.

Movements. Assumed to be resident; perhaps descends a little in severe winter weather, but no evidence of this.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in the Eastern Tibet EBA. Rare and little known. Confined to E part of Qinghai–Tibetan Plateau, where several large valleys cut into the plateau, including those of R Tongtian (upper reaches of Chang Jiang, or Yangtze), R Lancang Jiang (upper Mekong) and R Nu Jiang (upper Salween); known from Qumarlab S to Chamdo and from Zadoi E to Yushu; in 1997 a healthy population was found on Kanda Shan Pass, 90 km SW of Yushu. Global population thought to be small. Appears to be rare and localized, existing in "pockets", and seemingly absent from extensive areas of suitable-looking habitat. Further research needed, not only in looking for new sites, but also in assessing the species' habitat requirements, with particular emphasis on effects of grazing by yaks and its winter survival techniques.

Bibliography. Anon. (2010c), Armani (1985), Butchart & Stattersfield (2004), Byers, Olsson & Curson (1995), Collar *et al.* (1994), Olsson (1995), Robson (1986), Schäfer (1938), Schäfer & Meyer de Schauensee (1939), Stattersfield & Capper (2000), Thewlis & Martins (2000).

41. Black-headed Bunting



Emberiza melanocephala

French: Bruant mélanocéphale **German**: Kappenammer **Spanish**: Escribano Cabecinegro

Taxonomy. *Emberiza melanocephala* Scopoli, 1769, Carniola, Slovenia.

Forms a superspecies with *E. bruniceps*, and both sometimes placed in genus *Granativora*; recent phylogenetic study indicates that they are closely related to *M. lathami*. Hybridizes with *E. bruniceps* in area of Caspian Sea. Monotypic.

Distribution. Breeds in SE Europe from Italy and Balkans E to Black Sea coast, from E Ukraine (E of R Dnieper) and SW Russia E to NW Caspian region and S to N Caucasus region (absent from Greater Caucasus) and, in S, from Aegean islands and Turkey E to E Georgia, Azerbaijan and NE & SW Iran (in S locally E to Baluchistan) and S to Israel, W Jordan and N Iraq. Winters in W India.

Descriptive notes. 15·5–17·5 cm; 23–33 g. Fairly large bunting with rather long bill, lacking white in outer tail. Male breeding is distinctive, with head black, side of neck and throat bright yellow; nape and upperparts, including lesser upperwing-coverts, reddish-brown to bright chestnut; tail feathers black-brown, outer pair narrowly edged buff-brown; median and greater upperwing-coverts brown with pale buffish edges (forming two wingbars), flight-feathers and tertials black-brown with narrow pale buffish edges; bright yellow below, side of breast more rufous, occasionally with some rufous tinge on flanks; iris dark brown; bill rather long, lead-blue, often duskier on culmen; legs deep flesh-coloured. Male non-breeding (fresh plumage) is like breeding male, but black head feathers have sandy fringes, and colour of upperparts obscured by greyish-brown feather fringes. First-winter male has greyish crown streaked dark, supercilium, lores, side of neck and throat pale buff, ear-coverts, nape and most of upperparts greyish-brown and all faintly streaked, uppertail-coverts and lesser upperwing-coverts greyish-brown, breast tinged pinkish-buff, especially at side, belly paler with some yellowish wash, undertail-coverts pale yellow; very similar to *E. bruniceps* in similar plumage (often not separable in the field). Female breeding is similar to first-winter male, but paler and greyer; some have rufous tones on upperparts or side of breast as on male breeding. Female non-breeding is rather similar to breeding, thus similar also to first-winter male, but sometimes with yellow on throat, breast, belly and/or undertail-coverts; very similar to corresponding plumage of *E. bruniceps*, but forehead and crown on average more streaked (never unstreaked), and rump less yellow, also can appear shorter-tailed, larger-billed, with longer primary projection and more yellow below. First-winter female is virtually indistinguishable from first-winter male. Juvenile is rather similar to female breeding, but feathers on forehead, crown, neck, mantle and back brown with distinct buff edges, rump lacks obvious yellow or rufous (normally has a few tiny spots), chin to belly whitish, hint of a band across chest formed by dark brown shaft streaks, side of chest, side of belly and flanks on average more buffish-tinged. Voice. Song, normally from vantage point such as treetop, wire or rock, also in flight, usually a short series of "zrt" notes followed by a slightly accelerating phrase at low pitch, "zrit zrit srutt srutt-srutt sutteri-sutt sutterrih" or "zrt zrt priiprii chi-chiwu-chiwu ze-triiiuurr". On breeding grounds calls rather varied, e.g. "chiip", "chleep" or

"chlip" like those of House Sparrow (*Passer domesticus*), also "dzuu" or "prriu" like some notes of Eurasian Bullfinch (*Pyrrhula pyrrhula*); flight call "chuhp" like that of *E. citrinella*, also sharp "tsik" similar to that of *E. hortulana*. All vocalizations very similar to those of *E. bruniceps*, and normally very difficult or impossible to distinguish by human ear, being only a little less thin or less metallic than latter's.

Habitat. Breeds in open areas with dispersed trees, shrubs and hedges, from sea-level locally to c. 2000 m, exceptionally to 2900 m. Common in olive groves, orchards and vineyards, and in thickets or groves along field borders, in open forests with undergrowth, in open fields with thorny scrub, and on slopes of mountains with dense vegetation (for nest-sites) and vantage points (for songposts). Also, less commonly, in forested areas, maquis, wooded steppes and thickets, where it favours dense and tall bushy vegetation. Seems to avoid damp localities. In winter found on cultivated fields, also in scrub-jungle, roosting in thorn-scrub and thickets; mainly in plains.

Food and Feeding. During breeding season mostly invertebrates, also seeds and other plant material. Recorded invertebrates in diet include larval mayflies (Ephemeroptera), crickets (Orthoptera), earwigs (Dermaptera), cicadas (Cicadidae), larval Lepidoptera and Diptera, ants (Formicidae), beetles (Coleoptera) and hartvestmen (Opiliones). Among plant material recorded are seeds of bugloss (*Anchusa*) and *Salvadora*, and of grasses (Poaceae) including millet (*Pennisetum*, *Panicum*), wheat (*Triticum*), maize (*Zea*), *Sorghum* and rice (*Oryza*). Normally forages on the ground or in bushes or low in trees. Occurs singly and in pairs when breeding; postbreeding flocks in Israel can number a few dozen individuals to hundreds; on spring migration, flocks mostly of 10–30 (50) birds; in winter found in medium-sized to large flocks, sometimes numbering several thousand, often mixed with *E. bruniceps*; the two roost together in sometimes huge numbers, frequently associated with other passerines.

Breeding. Season starts mid-May and at peak during Jun; normally single-brooded, possibly sometimes two broods. Male performs song flight, flying on level course with shallow wingbeats and dangling legs, less often ascending at angle and parachuting down on spread wings. Territory size c. 17 ha per pair, and mean distance of 230 m between close territories. Nest built by female, a loosely constructed cup of grass and dead leaves, with lining of finer grass, rootlets, stems and hair, often brightly coloured flowerheads on outside of structure, located normally below 2 m under thorny shrub, low bush or vine, sometimes up to 3 m above ground in low tree; in study in Italy, preference for cardoon (*Cynara cardunculus*), common golden thistle (*Scolymus hispanicus*) and milk thistle (*Silybum marianum*) noted. Clutch 4–5 eggs, rarely 6 or 7, pale greenish-blue, finely spotted with dull reddish-brown; incubation by female, 10–16 days, usually 13–14 days; role of male in brood-tending unclear, in some studies reported as contribution very little or nothing, in others male fed chicks, nestling period 14–16 days; juveniles remained in vicinity of nest, less than 100 m from it, for 3–4 days before dispersing. Losses of clutches due mostly to adverse weather (storms) and the activity of snail-pickers.

Movements. Migratory; winters in W India, mainly in plains in Rajasthan, Gujarat, Madhya Pradesh, Maharashtra and N Karnataka. Seems to be rather scarce visitor in Nepal, mostly in E lowlands. Leaves breeding grounds late Jul and Aug; flies on rather direct SE heading, apparently at good speed, as it can arrive in wintering areas in India as early as Aug–Sept. Vacates winter quarters during Mar–Apr; regular in low numbers on passage across Arabia. Regular spring vagrant in W Europe (records N & W to Iceland, Fennoscandia, Ireland, Britain and Spain) and N Africa (Morocco, Algeria, Tunisia); recorded also in C Asia (L Baikal area). Also, recorded recently with degree of regularly in E Asia, mainly offshore Korea and S Japan and mainland E China (Fujian), as well as Thailand, Laos, Hong Kong and Borneo.

Status and Conservation. Not globally threatened. Common to locally very common. Breeding population of Europe estimated at 2,800,000–9,300,000 pairs. Densities can be locally very high, reaching concentrations of 137 pairs/km², but usually 30–50 pairs/km² in areas of optimal habitat; in an Italian study, average of 1·2 males/10 ha, with an excess of males reported. Has bred in France and Switzerland. Regularity of records of supposed vagrants in E & SE Asia has led to speculation that this species may have an additional, as yet undiscovered breeding population in that part of world; further fieldwork required. Global population thought to be declining because of changes in agricultural practices and removal of hedges and shrubs in parts of its range. Conversion of richly structured fields to intensive agriculture, creating larger fields and at same time extending use of pesticides, has been particularly evident in Greece, where olive groves replaced by maize fields, and in Slovenia, where corn fields replaced by commercial fruit-growing. Large decrease in breeding numbers between 1970 and 1990, after which a slight increase noted during 1990–2000, mainly in Turkey, the species' stronghold; this small increase has not yet brought population back to its previous levels.

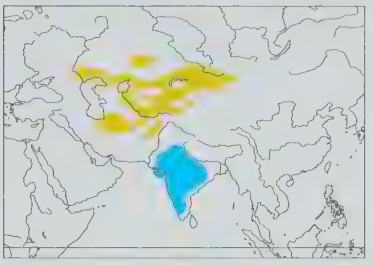
42. **Red-headed Bunting**



Emberiza bruniceps

French: Bruant à tête rousse **German**: Braunkopfammer **Spanish**: Escribano Carirrojo

Taxonomy. *Emberiza bruniceps* J. F. Brandt, 1841, Turkmenistan.

Forms a superspecies with *E. melanocephala*, and both sometimes placed in genus *Granativora*; recent phylogenetic study indicates that they are closely related to *M. lathami*. Hybridizes with *E. melanocephala* in area of Caspian Sea. This species has sometimes been referred to by name *E. icteria*, but present name has priority. Monotypic.

Distribution. Breeds from the Volga–Ural interfluve (S from just N of Caspian Sea, c. 51° N) E through Kazakhstan to S Altai Mts, W Mongolia and NW China (Xinjiang), and S to NE Iran, Turkmenistan, NW & E Afghanistan, Uzbekistan, Tajikistan and Kyrgyzstan. Winters in India.

Descriptive notes. 15–16·5 cm; 18–34 g. A fairly large bunting with relatively long tail, and without white on outer rectrices. Male breeding is very distinctive, with head down to breast red-brown, hindneck and most of upperparts yellowish-olive, mantle and back with dark streaks, scapulars with brownish outer webs, rump yellow, uppertail-coverts brown (often tinged yellowish); lesser upperwing-coverts yellow-olive, rest of wing feathers dark brown, median coverts with broad buff to whitish tips, greater coverts and flight-feathers (including tertials) with buff fringes, often bleaching to whitish at tips of greater coverts and forming a weaker second pale wingbar; side of neck and underparts below breast bright yellow; iris dark brown; bill blue-grey, a little darker on tip, sometimes tinged pinkish at base; legs pale flesh-coloured. Male non-breeding is similar to previous, but feathers of fresh plumage have pale fringes, concealing general bright pattern of summer plumage created by colour of feather centres; rufous apparent on breast and ear-coverts. First-winter male and female are broadly similar to female non-breeding, with less rufous tones on breast and upperparts, buffish-white breast, usually with fine streaks, and more streaked grey-brown upperparts without yellow-green tones of adult, especially on rump; normally inseparable from equivalent plumage of *E. melanocephala* under field conditions, but primary projection marginally shorter, with usually 3–4 exposed primaries beyond tertials (*E. melanocephala* normally 4–5, rarely 6), and bill marginally shorter. Female breeding is in general similar to first-winter, with less marked streaks on upperparts, bright yellow rump (absent in first-winter plumage on both sexes), and dirty yellowish-white underparts; many exhibit male characters, such as chestnut on forecrown, face, and chin to breast centre. Female non-breeding (after moult in winter quarters) is rather similar to breeding, but some have yellow more apparent on underparts. Juvenile is generally buffish in general appearance, including most of head feathers, with heavily dark-streaked golden-buff mantle (looking almost scalloped), some spots on breast, and with pale yellow undertail-coverts. Voice. Song, normally from top of bush or wire, often in flight, a rather monotonous repetition with few variations at accelerating rate with clear "r" sound, "zrit zrit srutt srutt-srutt sutteri-sut sutterih", finally dropping slightly in pitch, very similar to song of *E. melanocephala*. Calls are variations of "chip", "chuupp", "zriit" and sharp "tsit", also a quick series of clicks, "ptt-r-r-r"; much as calls of *E. melanocephala*.

Habitat. Isolated patches of bushes on pure steppes, also in semi-desert and desert oases; occupies all kinds of tall herbaceous vegetation and shrubs. Typical also of cultivated areas near water and irrigation. Generally in drier terrain, warmer and more sunny open country, with fewer trees or high bushes, than areas occupied by *E. melanocephala*. Can reach high altitudes, to 3000 m, during breeding season. On migration occurs in forest belts, riparian forest, groves, gardens and tall thickets. In winter quarters, found especially in cultivated fields with cereals and grains, often sharing habitat with *E. melanocephala*.

Food and Feeding. Takes seeds throughout year; during breeding season, feeds mostly on invertebrates. Among invertebrates recorded in diet are damselflies and dragonflies (Odonata), grasshoppers and crickets (Orthoptera), mantises (Mantodea), bugs (Hemiptera), lacewings (Neuroptera), adult and larval Lepidoptera, flies (Diptera), ants, wasps and bees (Hymenoptera), beetles (Coleoptera), spiders (Araneae), ticks (Acari), snails (Pulmonata). Among plant material recorded in diet are seeds and other parts of goosefoot (*Chenopodium*), and some grasses (Poaceae) such as millet (*Pennisetum*, *Panicum*), oats (*Avena*), wheat (*Triticum*), *Sorghum* and rice (*Oryza*). In winter probably feeds on same seeds as *E. melanocephala*, as the two exploit similar habitats. Feeds mostly on ground, but also in shrubs and bushes. Singly and in pairs when breeding. In winter typically found in medium-sized flocks, but sometimes of up to several hundred birds; often in large mixed flocks with *E. melanocephala*; the two roost together, sometimes in huge numbers, frequently with other passerines.

Breeding. Season May–Aug, including nests with eggs until mid-Jul; apparently single-brooded, but occasional second broods reported. Male performs song flight, flying on level course with shallow wingbeats. Distance between territories of different pairs often quite small. Nest built by female alone, escorted by male, taking 2–4 days, composed of old and green grasses, lined with dry herbs, leaves and shrubs, placed near ground or occasionally higher, up to 4 m above ground, in juniper (*Juniperus*) or other dense bush, or sometimes under grasses near tree cover. Clutch normally 2–5 eggs, rarely 6, pale bluish-white and delicately spotted; incubation by female, period 10–14 days; chicks fed by both parents, nestling period 12–13 days. Breeding success probably low, with likelihood of high levels of losses of first clutches.

Movements. Migratory; winters in most of NC & peninsular India. Nocturnal migrant. Autumn migration starts very early, with departure from N areas during second half Jul, and most having deserted breeding grounds by Aug; movement continues through end of Sept to beginning of Oct in S Kazakhstan, and first arrivals in Pakistan during end Jul, with passage still apparent until Sept. Spring migration begins in Mar, but conducted mostly during Apr–May, reaching S parts of breeding range during end Apr to mid-May and later, from second half May, in N part of range; breeding territories first occupied during early May. Recorded as extralimital in Sri Lanka, Nepal and Xizang (Tibet), and has reached E Asian coast on several occasions, e.g. Beijing (China), Korea and Japan. Recorded also in many countries in W Europe, including Iceland, where most considered to have involved escaped captives; recent analysis of records in Britain, France and Italy suggests that at least some could involve genuine vagrants, especially in cases of first-winter individuals in autumn.

Status and Conservation. Not globally threatened. Common to locally very common. Considered common in Kazakhstan. No evidence of any declines in any parts of breeding range, and global population considered stable. Appears common in non-breeding range.

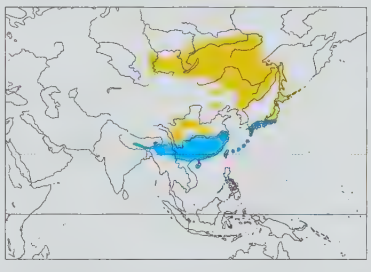
43. Japanese Yellow Bunting

Emberiza sulphurata

French: Bruant du Japon **German**: Schwefelammer **Spanish**: Escribano Japonés
Other common names: Japanese/Yellow Bunting

Taxonomy. *Emberiza sulphurata* Temminck and Schlegel, 1848, Japan.
Sometimes placed in a separate genus, *Ocyris*. Recent phylogenetic study suggests that this species is closely related to *E. pusilla*, *E. rustica*, *E. aureola*, *E. rutila* and *E. spodocephala*, forming a subclade with them; it has been suggested that they form a polytomous group of species, probably the result of a rapid, "simultaneous" radiation. Monotypic.
Distribution. Breeds in mountains of N & W Honshu, in Japan. Main wintering area imperfectly known: includes N Philippines, probably also Taiwan and SE China (Fujian, Guangdong).



Descriptive notes. 13–14 cm; male average 15·2 g, female average 14·6 g. Rather small, undistinctive bunting. Male breeding has head uniformly greenish, with some grey tinge, white eyering, lores and chin black, throat yellowish; nape grey, tinged green, grading into greyish-green on upperparts, where mantle and scapulars with dark streaks (back to uppertail-coverts with streaks absent or very ill-defined); central rectrices dark brown, the rest blackish-brown, outer pair with much white on both webs, next pair with white wedge on inner web; lesser upperwing-coverts greyish-green, median coverts blackish with broad pale buff to whitish tips, greater coverts blackish with buffy fringes and pale buff to whitish tips (forming a second obvious wingbar), tertials blackish-brown with cinnamon-buff outer edges, primaries and secondaries brown with pale edges, those of secondaries more cinnamon-buff; underparts yellowish, tinged greenish, side of breast tinged greyish-green, rear flanks with dark streaks, undertail-coverts pale yellow; iris dark chestnut-brown; bill blue-grey; legs pinkish. Male non-breeding is very similar to breeding, but lores greyish, no black visible on chin, has ill-defined malar stripe, general colour of head is browner with greyish tinge (not so green as during breeding), mantle tinged brownish, uppertail-coverts tipped olive, wingbars are buffier and less prominent. First-winter male is similar to non-breeding, but browner tinge more apparent, especially on breast, and lesser upperwing-coverts tinged olive; iris dark grey-brown. Female breeding is similar to male, but with paler lores and no black on chin, upperparts more brown, less green, and underparts more buffish-yellow, breast tinged brown. Female non-breeding is similar to non-breeding male, but head and upperparts still browner compared with breeding plumage. First-winter female is rather similar to non-breeding adult, but with faint streaks on breast and lesser upperwing-coverts olive-tinged. Juvenile is similar to first-winter, crown showing some streaks, but in general head is plain, with no contrast between ear-coverts and submoustachial stripe, unlike *E. spodocephala*. Voice. Song, usually from inconspicuous perch high in tree, usually several twittering phrases alternated, "twee twee tsitsit prewprew zrii", and then "ziriritt zeezee tew" followed by "psew zereret zeetew", after such phrases sometimes a variable twittering, but usual ending a single "zrii" or low-pitched "tew"; similar to song of *E. spodocephala*, but shorter. Call a metallic "tsip", similar to that of *E. tristrami* and *E. rutila*, softer than similar note of *E. spodocephala*.
Habitat. During breeding associated with second growth and forest edges in deciduous and mixed forests, also in park-like areas with shrubs and thickets; foothills and lower slopes of higher mountains, usually at middle altitudes, 500–1500 m. On migration found in shrubby clearings in open woodland, as well as in cultivations with scattered bushes. During winter in weedy and bushy areas, grasslands and agricultural areas to 1500 m.
Food and Feeding. Diet not well known. Insects, such as beetles (Coleoptera) and caterpillars, also plant material, such as legume seeds. On Mindoro, in Philippines, seen to feed on yellowish grass seeds fallen to ground after burning of tall grasses. Forages on ground. During migration and in winter often in small flocks.
Breeding. Starts second half of May. Males congregate on areas of snow-free vegetation, awaiting later arrival of females. Nest made from coarse grass, normally placed on lower branch of bush usually below 2 m high, but not on ground. Clutch 3–4 eggs, pale brownish-white, smeared and mottled with lavender-grey and light brown, with some spots, irregular short lines and streaks. No other information.
Movements. Migratory; non-breeding quarters mainly in N Philippines, with irregular records Taiwan and Chinese coast (Fujian S to Hong Kong). Leaves breeding territories late Aug to Oct; in spring regularly recorded as scarce passage migrant in Hong Kong and Korea, especially during Apr, and several records in E China on Shaweishan I (off Shanghai) during spring migration; arrival on breeding grounds from late Apr, mostly in May. At least formerly, some individuals apparently remained all year in Japan, with scattered winter records in S Honshu S to Ryukyu Archipelago.
Status and Conservation. VULNERABLE. Restricted-range species: present in Central Honshu Montane Forests Secondary Area. Uncommon; declining. No reliable population estimates; further study needed. Has been suspected to breed locally in S Japan (Kyushu). Thought to have suffered moderate decline, since it has become rarer in traditional breeding areas, with more significant fall in numbers during 20th century. Decrease attributed mainly to habitat degradation and loss, chiefly through intensification of agriculture, and also trapping for cagebird trade in Japan in the past, but now probably more importantly in S China wintering/passage areas (where huge numbers of *E. aureola* still hunted for human consumption). Although not well documented, use of pesticides seems also to be correlated with this species' decline; it has caused similar problems in several Asian countries, and is especially linked with rapid decline of small passerines in rural areas of S mainland China. Use of toxic chemicals in cultivated fields probably one of key reasons for rapid decline in breeding numbers. Present during breeding season in several protected areas in C Honshu, including Asama National Protection Area (Gunma and Nagano Prefectures), Northern Alps National Protection Area (Toyama, Nagano and Gifu Prefectures) and Katano Duck Pond Protection Area and Special Protection Area (Ishikawa Prefecture); occurs during passage in other protected areas of Japan, as well as in Hong Kong (Mai Po marshes). Legally protected in Japan, North Korea and Hong Kong.
Bibliography. Alström *et al.* (2008), Anon. (2010c), Armani (1985), Austin & Kuroda (1953), Brazil (1991, 2009), Butchart & Stattersfield (2004), Byers, Olsson & Curson (1995), Collar *et al.* (1994), David *et al.* (2009), Jahn (1942), Kanouchi *et al.* (1998), Maki & Onishi (2000), Stattersfield & Capper (2000), Takano *et al.* (2001), Temme (1974), Tomek (1997, 2002), Vietinghoff-Scheel (1992), Xiong Lihu *et al.* (2006).

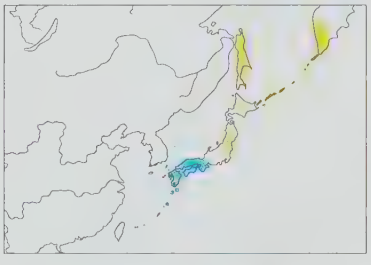
44. Black-faced Bunting

Emberiza spodocephala

French: Bruant masqué **German**: Maskenammer **Spanish**: Escribano Enmascarado
Other common names: Grey-headed Black-faced Bunting; Masked Bunting (*personata*)

Taxonomy. *Emberiza spodocephala* Pallas, 1776, Daurian Range, southern Chita, south-eastern Siberia, Russia.
Sometimes placed in a separate genus, *Ocyris*. Recent phylogenetic study suggests that this species is closely related to *E. pusilla*, *E. rustica*, *E. aureola*, *E. rutila* and *E. sulphurata*, forming a subclade with them; it has been suggested that they form a polytomous group of species, probably the result of a rapid, "simultaneous" radiation. Distinctive race *personata* possibly represents a separate species; further study required. Nominate race exhibits slight clinal variation in colour, with increasing green on crown, nape and throat and more yellowish underparts from W to E, but individual variation also significant, and populations at extremes of cline not well differentiated; proposed races *oligoxantha* (described from Kuznetsk region of SC Siberia) and *extremiorientis* (from S Ussuriland) represent respective ends of this cline. Three subspecies recognized.
Subspecies and Distribution.
E. s. spodocephala Pallas, 1776 – breeds from C Siberia (Novokuznetsk and Krasnoyarsk) E to S coast of Sea of Okhotsk, N Sakhalin I and Sea of Japan coast, S to Sayan Mts, Altai, N Mongolia (Khentii Mts), Transbaikalia, NE China (Heilongjiang), SE Russia (Ussuriland) and N Korea; winters in S & E China (S Yunnan and Hainan E to Fujian) and Taiwan.
E. s. personata Temminck, 1836 – breeds S Sakhalin I, Kuril Is and Japan (Hokkaido S to C Honshu); winters from N Honshu S through Shikoku and Kyushu to Ryukyu Is and Izu Is.
E. s. sordida Blyth, 1845 – breeds EC China from N Gansu and NE Qinghai S to W Sichuan and N Yunnan (S to Yangtze Valley), E to N Hubei, and occasionally in C Guizhou and W Hunan; winters in area from C Nepal E to NE India, N Myanmar and N Indochina.

Descriptive notes. 13·5–16 cm; 13–27 g. Male nominate race breeding has head to breast olive-grey (becoming greener from W to E of range), contrasting blackish lores and chin, nape tinged brownish; mantle pale brown with black streaks, centre of mantle and scapulars darker, tinged chestnut, back like mantle with a few indistinct streaks, rump and uppertail-coverts plain grey-brown; tail dark brown, outer rectrices with extensive white; lesser upperwing-coverts grey-brown, median coverts blackish-brown with pale buffish tips, greater coverts with greyish-brown edges and light buff tips (forming a second, rather weaker wingbar), tertials blackish with brown fringes, primaries and secondaries dark brown, primaries with pale edges, secondaries with rufous edges; underparts below breast pale yellow (becoming darker towards E of range), well demarcated from grey of breast, some rufous streaks on flanks, streaks becoming darker posteriorly; iris dark chestnut-brown; upper mandible blackish with whitish-horn cutting edges, lower mandible pinkish with dark tip; legs pinkish-brown. Male non-breeding is similar to breeding, but slight differences in colour tones: freshly moulted feathers of crown and ear-coverts fringed chestnut, concealing to some extent general grey-olive appearance of plumage, and pale fringes of breast and throat feathers somewhat conceal general colour of these areas; breeding colour gradually appear as feather fringes increasingly abraded. First-winter male is very similar to non-breeding, except that head pattern more like that of female because of broader browner fringes on fresh feathers, streaking on breast less prominent than on female, iris grey-brown. Female breeding is similar to male breeding, but head pattern different, with some individual variation in extent of olive-grey saturation, nape browner, crown streaked dark chestnut, has pale lores (not black as on male), pale supercilium, submoustachial stripe and throat; some have olive-grey on breast. Female non-breeding and first-winter female are similar to female breeding, but with more prominent appearance of browner tones in general, first-winter with iris grey-brown. Juvenile is similar to first-winter female, but crown almost uniformly grey-brown with some indistinct dark brown streaks, ear-coverts uniform and darker brown, mantle and scapulars duller, throat finely spotted, throat and belly tinged brown, also fine streaks on breast. Races differ mainly in colour tones and head pattern: *personata* is distinctive, brighter than nominate, greener on crown, more yellow below, with centre of throat to breast pure yellow (or almost so) without greenish or greyish tones, breast and flanks often more heavily streaked, bill larger and wing longer; *sordida* resembles nominate in pattern, but green and yellow pigments darker and richer, similar to those shown by previous, and facial mask (lores and chin) of male better defined, larger and blacker. Voice. Song of nominate, usually from inside bush or low tree, consists of variable succession of ringing chirps and thrills, "chi chi chu chirri chu chi zeee chu chi chi", in some ways reminiscent of that of *E. schoeniclus*; song of *personata* similar, but tempo slower, broken into short phrases, and more monotonous. Call normally a thin, ticking and sharp "tzii", not unlike contact call of Song Thrush (*Turdus philomelos*).
Habitat. Breeds in shrubby and tall dense grass areas with interspersed trees along watercourses and floodplains, also in mixed forest and moist coniferous forest. Also in bushes and thickets in open areas in sparse woodland, gardens, and forest edges and clearings, avoiding densely forested areas. Occasionally in mountain forests, deciduous or coniferous, to at least 600 m in Altai and, in Japan, to 1500 m and sometimes in subalpine birch (*Betula*) forests at higher altitudes; to at least 1300 m in N Mongolia. In winter descends to lower areas, then present in foothills and lowlands, usually in hedges and shrubby areas near running water or on edges of wooded areas and clearings, as well as on rice stubbles, crops, edges of pools and riverbeds; also in gardens, urban and suburban parks, in forest undergrowth, tall grass fields, dwarf bamboo and sugar cane.
Food and Feeding. Adult diet during breeding mainly adult and larval invertebrates, such as small cicadas (Cicadidae) and other bugs (Hemiptera), flies (Diptera), ants (Formicidae), caterpillars (Lepidoptera), beetles (Coleoptera) and spiders (Araneae). Nestling diet similar. In study in riparian forest in Japan, found to feed mainly on small aquatic invertebrates. During migration and on wintering grounds, cereal grains and variety of other seeds. Forages mostly on ground. Outside breeding season generally in small groups, sometimes mixed with congeners.



On following pages: 45. Grey Bunting (*Emberiza variabilis*); 46. Pallas's Bunting (*Emberiza pallasi*); 47. Ochre-rumped Bunting (*Emberiza yessoensis*); 48. Reed Bunting (*Emberiza schoeniclus*).

Breeding. Season starts usually between May and mid-Jun, depending on location and altitude, with fledglings as late as Sept; two broods. Nest, built apparently by female alone, of soft dry grass, lined with hair, placed on ground or in low bush or herb, for second clutches sometimes up to 1·5 m above ground. Clutch 4–5 eggs, pale greenish or bluish-white to pinkish-white, mottled dull maroon or umber, sometimes also with purplish-brown, covered with dark spots and lines; incubation by female, period 12–14 days; chicks fed by both sexes, nestling period 9–14 days.
Movements. Migratory. Leaves Siberian breeding grounds during early Sept and NE China (Heilongjiang) in Oct, but in Japan still present Oct–Nov, since many winter in S part of that country; main autumn passage in Korea during Sept–Oct. Present on wintering grounds Oct–May. Spring migration through NE China and Korea in Apr and May, reaching breeding grounds in Heilongjiang during Apr and N Siberia in May; return to breeding territories in Japan during Apr. Recorded as vagrant in W Europe (Britain, Netherlands, Germany, Norway, Finland and France), although captive origin of some of these not fully excluded; recorded also in Indonesia (Taliabu I, E of Sulawesi).
Status and Conservation. Not globally threatened. Common in suitable habitat throughout range; one of the commonest buntings in E Asia. Common also in non-breeding range. Global population not quantified, but no evidence of any declines and considered stable.

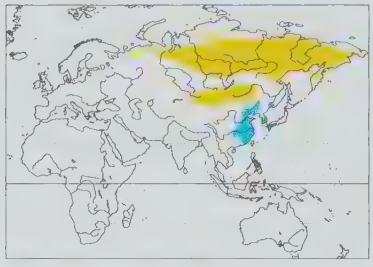
45. Grey Bunting
Emberiza variabilis

French: Bruant gris **German**: Bambusammer **Spanish**: Escribano Gris
Other common names: Japanese Grey Bunting

Taxonomy. *Emberiza variabilis* Temminck, 1836, northern Japan.
Sometimes placed in a separate genus, *Ocyris*. Recent phylogenetic study suggests that this species may be sister to *E. tristrami* and *E. chrysophrys*. Birds from Kamchatka sometimes separated as race *musica*. Monotypic.
Distribution. Breeds E Russia (S Kamchatka), Kuril Is, Sakhalin I and Japan (Hokkaido S to C Honshu). Winters mainly in S half of Honshu, Shikoku, Kyushu and Ryukyu Is (S to Okinawa).



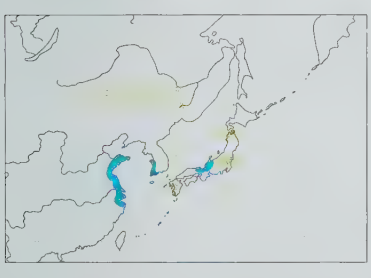
Descriptive notes. 14–17 cm; 20·9–30 g. Male breeding is distinctive, sometimes with dusky lores, otherwise entire head, upperparts and underparts dark slate-grey, mantle with some blackish-brown streaks, belly somewhat paler, undertail-coverts with whitish feather edges; tail dark brown, feathers with bluish-grey edges; upperwing-coverts also slaty grey, centre of each feather darker, tertials dark brown with greyish (on inner feather) to rufous-brown (outer tertial) edges, primaries and secondaries dark brown with grey-brown or brownish edges; iris dark chestnut-brown; upper mandible dark grey with pale pinkish cutting edge, lower mandible pale pinkish with blackish on tip and along part of underside; legs pinkish. Male non-breeding is very similar to breeding, but grey areas of plumage partly obscured by brownish or buffish fringes of fresh feathers; brown fringes may give impression of lateral crownstripes, and buffish fringes can help to produce impression of faint supercilium and median crownstripe. First-winter male has crown olive-grey, tinged rufous, slate-grey supercilium, ear-coverts, sides of neck and throat; mantle and scapulars olive grey-brown, streaked dark brown, back to uppertail-coverts slate-grey with rufous-chestnut feather tips (tips partly concealing general slaty pattern), greater and median upperwing-coverts blackish with blue-grey edges and buffish tips (two wingbars), blackish-brown flight-feathers, tertials with rufous outer edge at tip of inner web, primaries and secondaries with buff edges (more rufous on secondaries), tail blackish-brown, central pair of rectrices rufescent brown; underparts buffish-white mixed with pale slaty, palest on belly, some streaks on flanks; iris dark grey-brown. First-summer male is similar to male breeding, but with brownish cast, and rump shows some rufous. Female breeding is similar to first-winter male, lacking slaty tones on head, rump and underparts, has malar stripe greyish, throat and underparts whitish-buff with dusky streaks, belly whiter; iris dark chestnut-brown. Female non-breeding is similar to breeding, but with fresh plumage. First-winter female is similar to female non-breeding, but upperparts more rufescent, supercilium, submoustachial stripe and throat paler, and iris dark grey-brown. Juvenile has olive-buffish supercilium and lores, with ear-coverts and side of neck olive-brown, malar stripe dark greyish, mantle more diffusely streaked than in subsequent plumages, scapulars chestnut-brown with dark centres, back, rump and uppertail-coverts uniformly rufous-chestnut, breast olive-buffish with more prominent black streaks than in subsequent plumages, belly and flanks indistinctly streaked; iris dark grey-brown, legs pinkish. Voice. Song, from inconspicuous perch inside bush or undergrowth, usually starts with soft drawn-out note, and is slow, with 3–5 distinctive notes, "swee swee chi-chi-chi" or "hsuuu twis-twis-twis", or quicker versions e.g. "hsuuu tsisisisisis". Call a sharp "tzii", similar to that of *E. spodocephala*.
Habitat. Favours mixed deciduous and coniferous forest at middle and subalpine elevations, usually with dense vegetation, with undergrowth and thickets of dwarf bamboo (*Sasa paniculata*); also in alder (*Alnus*), willows (*Salix*) and birch (*Betula*) forests. In mountains and hills, from c. 1000 m to 1800 m. During winter found in dense vegetation, usually in evergreen-forest undergrowth near streams; also in parks and suburban gardens, even in centre of big cities (e.g. Tokyo), and in open cultivations where isolated stands of trees present.
Food and Feeding. Diet insufficiently known; appears to include small invertebrates, seeds and small fruits and berries. Usually forages on ground. Secretive. Generally singly and in pairs, including in non-breeding season; during migration sometimes in small groups of up to five or six individuals.
Breeding. Season begins during Jun, with peak in Jul. Nest built from twigs and dead leaves of dwarf bamboo, also grasses, located on stems of dwarf bamboo or in low bush, usually below 1 m. Clutch 3–5 eggs, greyish-white, with purple-greyish dashes at blunt end; incubation by both sexes, period 12 days; chicks fed by both parents, nestling period 11 days.
Movements. Migratory. Autumn migration begins in Aug in N part of range, but main passage in Kuril Is during Sept, with small number into Nov; leaves winter quarters during Mar and Apr, and main period of passage N in Kuril Is during second half May. Accidental in S Ryukyu Is (including Iriomote), and E coast of China (Shaweishan I, off Shanghai), Taiwan and Korea, also Commander Is, Vladivostok area of Russia, and Alaska (W Aleutians).
Status and Conservation. Not globally threatened. Uncommon in most of range; locally common. Global population not reliably estimated, but no signs of decrease and considered stable.
Bibliography. Alström *et al.* (2008), Armani (1985), Brazil (1991, 2009), Byers, Olsson & Curson (1995), Ezaki *et al.* (2007), Fujimaki & Hikawa (1978), Gibson & Hall (1978), Jahn (1939), Kanouchi *et al.* (1998), Koblik (1993), Kolomiitsev (1986), Konno & Fujimaki (2001), Kuroda (1932), MacKinnon & Phillipps (2000), Maki & Onishi (2000), Nakamura, H. (1986), Nakamura, T. (1978, 1983), Nechaev (1978), Stepanyan (1979), Takano *et al.* (2001), Uemura (1989).

46. Pallas's Bunting
Emberiza pallasi

French: Bruant de Pallas **German**: Pallasammer **Spanish**: Escribano de Pallas
Other common names: Pallas's Reed Bunting; Mongolian Bunting (*lydiae*)

Taxonomy. *Cynchramus pallasi* Cabanis, 1851, near Selenga River, Transbaikalia.
This species, together with *E. yessoensis* and *E. schoeniclus*, sometimes placed in genus *Schoeniclus*. Recent molecular study indicates that it is a sister-species to *E. schoeniclus*, with *E. yessoensis* as sister to both. Race *minor* of *E. schoeniclus* sometimes included in present species. Significance of geographical variation not fully understood, and possibly linked to variation in habitat preferences; further study required. Race *lydiae*, differing from others vocally and in ecology, possibly a separate species. Race *polaris* exhibits partially clinal variation, with gradation towards darker plumage and more heavily streaked rump in E of range. Proposed race *montana* and its synonym *suschkiniana* (described from SE Russian Altai) considered synonymous with nominate, and *latolineata* (from Kolyma Peninsula) with *polaris*. Three subspecies recognized.
Subspecies and Distribution.
E. p. polaris Middendorff, 1853 – breeds NE European Russia E in Siberia (S to basins of R Angara, R Lena and R Aldan) to Chukotskiy Peninsula, Sea of Okhotsk coast and N Kamchatka; winters in NE & E China, extreme SE Russia (S Ussuriland) and Korea.
E. p. pallasi (Cabanis, 1851) – breeds from Altai and Sayan Mts E to Transbaikalia and W Amurland (S of Tukuringra Mts) and S to N Mongolia and NE China (NW Heilongjiang), also disjunctly in E Tien Shan; winters in W & N China (Xinjiang and Inner Mongolia).
E. p. lydiae Portenko, 1929 – breeds from S Siberia (Tuva and S Transbaikalia) through N, C & E Mongolia, probably to adjacent NE China (NE Inner Mongolia); non-breeding probably in N China. Probable isolated population (race uncertain) in Ordos Mts, in N China.

Descriptive notes. 12–13·5 cm; 10–20 g. Small bunting, bill comparatively short and narrow with straight culmen. Male nominate race breeding has black head and throat, conspicuous white submoustachial stripe and hindneck-collar joining on side of neck; feathers of mantle and scapulars blackish, with some chestnut, especially towards tip, all fringed pale buff (bleaching to whitish), back pale buffish-grey with blackish streaks, rump and uppertail-coverts pale buffish (wearing to greyish-white), coverts with faint black streaks; tail brown, central feather pair darker and broadly edged pale on inner webs outermost pair with much white on both webs, adjacent pair with less white (variable); lesser upperwing-coverts grey, median and greater coverts black with white or whitish tips (forming two clear wingbars), greaters also with pale edges, flight-feathers blackish, tertials with well-defined narrow pale yellowish edges, primaries and secondaries with narrow pale edges, these more light rufous-buff on secondaries (creating buffish pale panel on closed wing); underparts pale buffish-white, side of breast washed grey, few streaks on flanks; iris dark chestnut; bill blackish; legs pale flesh-coloured. Distinguished from similar *E. schoeniclus* mainly by smaller size, smaller bill with straight culmen, proportionately longer tail, generally colder plumage tones, more prominently streaked upperparts, grey (not rufous) lesser coverts, distinct pale wingbars (lacking reddish tones). Male non-breeding has black areas of plumage partly concealed by pale feather fringes, crown, ear-coverts and lores mostly sandy brown (instead of black) with dark streaks, superciliary area buffish, thin dark moustachial stripe, throat mottled black; upperparts brighter and more sandy-coloured, mantle with hint of rufous, wing feathers more broadly edged and tipped buffish (lesser coverts still grey), underparts strongly tinged yellowish-buff; lower mandible pinkish. First-winter male is like male non-breeding, but lesser coverts grey-brown (not ash-greyish), iris dark grey-brown. Female breeding is very similar to first-winter male, including grey-brown lesser upperwing-coverts and pinkish on lower mandible, but differs in having indistinct reddish-brown streaks on rump; iris dark chestnut, as on male breeding. Female non-breeding is very like male non-breeding, but with lesser upperwing-coverts grey-brown. First-winter female is almost identical to female non-breeding, differing only in more pointed rectrices and dark grey-brown iris. Juvenile is reminiscent of female breeding, but has dark-streaked olive-brown crown, paler supercilium, rufescent ear-coverts, blackish scapulars with buffish edges, pale sandy-brown rump with prominent brown streaks, grey-brown lesser coverts, usually prominent dark malar stripe, yellowish breast with bold, dense dark streaks, and dark grey-brown iris. Races differ mainly in darkness of plumage: *polaris* is on average slightly smaller and more heavily streaked than nominate, and in non-breeding plumage is somewhat darker on back, especially in E of range; *lydiae* is paler above than nominate during breeding, with upperwing-coverts and centres of back feathers brownish (instead of black) and edges pale buff. Voice. Song, normally from bushtop, also from top of tall grasses or herbs, a simple monotonous phrase containing series of same notes, e.g. "chi chi chi chi chi chi" or "srri srri srri srri srri srri srri"; song of *lydiae* similar in structure, but differing slightly in motif, "tsisi tsisi tsisi tsisi"; song of nominate apparently a little different, said to be not unlike a clear song phrase of Willow Tit (*Poecile montanus*) or *E. aureola*. Normal call a fine "chlip" or "tsilip", reminiscent of that of Eurasian Tree Sparrow (*Passer montanus*); also, a soft "dziuu" recorded from S birds breeding in the steppe.
Habitat. Breeds at high latitudes in tundra and forest-tundra with tall herbage, and shrubs (for songposts), and in river valleys in lowland tundra, with thickets of vegetation such as dwarf willow (*Salix*) or alder (*Alnus*); also in subalpine tundra in high mountains, e.g. in grasslands with dense *Rhododendron* and *Dasiphora* c. 1 m high at around 2000 m in Sayan Mts, S Siberia, and in patches of dwarf birch (*Betula nana*). Normally in drier and cooler areas than those favoured by *E. schoeniclus*. Race *lydiae* in drier habitats, mainly confined to stands of the tussock grass



Achnatherum splendens at interface between wetlands and steppe/desert steppe. Outside breeding season found in lowlands and plains, selecting irrigated areas with scattered shrubs and presence of reeds near rivers and lakes; also in grassy fields, rice fields and other cultivation.
Food and Feeding. Mostly invertebrates during breeding, and seeds and other plant material throughout year. Insects taken also during winter. Invertebrates reported in diet include adult Lepidoptera, adult and larval flies (Diptera), larval sawflies (Symphyta) and beetles (Coleoptera); among plant material are seeds of alder, crowberry (*Empetrum*) and *Stipa* grasses. Forages on ground, also at tip of low vegetation such as *Stipa* grasses, where it collects seeds; mostly in wet meadows, but also in willows and other small trees and shrubs, *lydiae* in dry tussock. Generally alone or in pairs when breeding. Outside breeding season feeds in large flocks, often mixed with other buntings as well as with Common Redpolls (*Carduelis flammea*).
Breeding. Season Jun–Jul in N of range, to Aug in S. Nest made from grasses and sedges (*Carex*), lined with fine grasses and hair, sometimes also with dried leaves of tree such as larch (*Larix*), placed on ground or low in bush, *lydiae* in tussock. Clutch 3–5 eggs, creamy to reddish-brown with dark spots and some fine irregular streaks (similar to those of *E. schoeniclus*); incubation mainly by female, period 11 days; chicks fed by both parents, nestling period 10 days.
Movements. Migratory. Race *polaris* winters mainly E China (C Heilongjiang S to Yangtze Valley), extreme SE Russia (S Ussuriland) and Korea, and is very rare winter visitor in S Japan; nominate race migrates mainly to W & N China; winter quarters of *lydiae* uncertain, probably N China. Post-breeding dispersal begins during late Jul, and departure from breeding grounds normally starts during Aug and continues through Sept. In C Siberia recorded mostly from early Aug to end Sept, passing in loose flocks of 5–10 individuals, with sometimes high concentrations and densities of several hundred birds/km² during Sept peak; main passage in S Siberia mid-Sept to end Oct, and main passage in NE China through Oct. Wintering areas occupied between Oct and Mar, with some individuals still present in these areas sometimes until May. Main spring passage through NE China and S Siberia during second half of Apr; in C Siberia passes mostly during May to early Jun, exceptionally to end Jun; arrival in N parts of breeding range during Jun. Recorded as vagrant in Alaska, Hong Kong and Taiwan; also in W & S Europe (Britain, Portugal, Italy).
Status and Conservation. Not globally threatened. Locally common to very common. Has extensive breeding range across N parts of Eurasia; also a probable isolated population in Ordos Plateau region of NC China, which would represent S limit of distribution, but confirmation of breeding still required. Densities in some tundra and forest-tundra areas high, e.g. 32 birds/km² in R Bolshiye Ury basin in C Siberia and 69–76 birds/km² in Yenisey forest-tundra; less numerous in patches of willow thickets on Yenisey floodplains, with densities of only 2–7 birds/km², and in similar willow-thicket habitat in E Taymyr slightly higher densities of 10·5–20 birds/km². Although global population not quantified, believed to be stable, and no clear evidence of any decline or substantial threats in vast area occupied during breeding. Only problem of some concern is the extensive killing of buntings for food in Chinese wintering range, where this species could suffer from indiscriminate hunting of bunting flocks, with which it associates at that season. Possible effects of global warming should perhaps be considered; melting of glaciers could cause deterioration of mountain habitats, and in S of breeding range raised temperatures could result in desertification of desert-steppe/steppe areas.

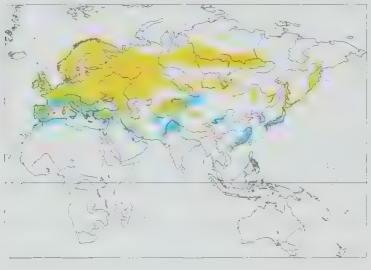
47. Ochre-rumped Bunting

Emberiza yessoensis

French: Bruant de Yéso **German**: Mandschurenammer **Spanish**: Escribano Culiocre
Other common names: Chinese Reed Bunting, Japanese (Reed) Bunting

Taxonomy. *Schoenicola yessoënsis* Swinhoe, 1874, near Hakodate, Hokkaido, Japan.
This species, together with *E. pallasi* and *E. schoeniclus*, sometimes placed in genus *Schoeniclus*. Recent molecular study indicates that it is a sister-species to both of those. Two subspecies recognized.
Subspecies and Distribution.
E. y. continentalis Witherby, 1913 – breeds in extreme E Mongolia, NE China (Heilongjiang) and S Russian Far East (Ussuriland); winters in coastal E China.
E. y. yessoensis (Swinhoe, 1874) – breeds in C & S Japan (N & C Honshu and Kyushu); winters in S Japan and Korea.

Descriptive notes. 14–15 cm; 13–14 g. Small bunting with pointed tail feathers. Male nominate race breeding has entire head to lower neck and upper breast glossy black, nape pinkish-tinged chestnut-brown, mantle and scapulars light grey-brown mixed with rufous with heavy black streaking, back to uppertail-coverts grey-brown with pinkish tinge; tail grey-brown, outer two pairs (occasionally also next pair) with white at tip and on inner web; lesser upperwing-coverts grey-brown to bluish-grey, median coverts black with broad rufous tips, greater coverts black along centre with rufous fringes broader on outer webs, tertials black with rufous edges, primaries and secondaries brown with thin light rufous edges on outer webs; underparts creamy white, breast with slightly darker wash; iris dark chestnut-brown; bill blackish; legs pink. Distinguished from *E. schoeniclus* and *E. pallasi* by lack of white submoustachial stripe. Male non-breeding is like male breeding, but pale fringes of recently moulted feathers partly conceal black of head, which often shows indication of paler supercilium and submoustachial stripe, and nape, side of neck, breast side and flanks washed rufous or orange-brown; bill has pinkish tones on cutting edges, and pinkish lower mandible. First-winter male is similar to male non-breeding, but fringes of feathers on crown and rest of head conceal even more of black pattern; iris dark grey-brown. Female breeding is similar to male non-breeding, but head mostly dark brown with some pale streaking, ear-coverts uniformly dark brown, submoustachial area and throat pale orange (wearing to white) with contrasting blackish malar stripe, latter often breaking up into black spots on side of breast; bill dark brown. Female non-breeding is similar to male non-breeding, but with darker tones; malar stripe still prominent, but usually not reaching base of bill. First-winter female is similar to female non-breeding, sometimes with some streaking on breast and flanks; iris dark brown, as on first-winter male. Juvenile has blackish crown with distinct pale median stripe, well-defined pale grey-brown supercilium, lores rather dark brown, ear-coverts light brown but blacker posteriorly, pale greyish-brown submoustachial stripe and throat, nape and upperparts yellowish-brown, mantle and scapulars heavily streaked, wing and tail similar to adult, breast yellowish with black spots, rest of underparts yellowish-white; iris dull brown. Race *continentalis* is very like nominate, but slightly paler and with pinker tones, less chestnut on upperparts and on wing, and to some extent less buffish below. Voice. Song, usually from tall herb or reed, a brief phrase containing short syllables, "tsui tsui chrin"; race *continentalis* slightly different, "chuwi chiwu siip pssriii dsiii". Call a short "tick"; flight call "bziu", similar to that of *E. schoeniclus*.
Habitat. Breeds in reedbeds and edges of marshes, wetland fringes with bushes, and tall herbs bordering rivers and lakes; in higher-lying areas also in wet meadows and drier grassland. In winter found in open cultivations and agricultural fields near water, as well as on coastal marshes.
Food and Feeding. Insufficiently known. During breeding recorded as taking seeds, beetles (Coleoptera) and caterpillars, also berries; in winter diet probably based mainly on seeds of grasses and marshland vegetation.
Breeding. Season May–Jul; double-brooded. Nest a small cup made from dry grasses, lined with grass, rootlets and hair, located on or very close to ground in grassy area. Clutch 3–5 eggs, ochraceous with brown spots and black lines; incubation by female, period 12–14 days; chicks fed by both parents, nestling period 10–13 days (mainly 11–12 days); parents begin second nesting attempt while still feeding fledglings of first brood.
Movements. Migratory. Mainland race *continentalis* migrates to coastal China (mainly from Jiangsu S to Fujian), and recorded exceptionally in Taiwan; nominate race in Japan makes post-breeding shift S to S & W Honshu and Korea. In C Honshu, arrival on meadows of Nagano generally not before May, and departure in Sept; was considered an early arrival on former breeding grounds on Hokkaido (N Japan). Phenology of movements along coastal E China insufficiently known. Recorded as vagrant in Hong Kong.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Uncommon to rare, and local. Evidently extinct in some formerly inhabited areas, such as Hokkaido and the Kuril Is, where no reports of persistence of populations during recent decades. Breeding recently confirmed in E Mongolia. Given its general scarcity across the whole area of its distribution, this species is considered to have a moderately small population, and appears to be in decline. Was reported as more abundant a century ago. Although reasons for its decline not confirmed, every indication is that it is related to continuing general loss and degradation of wetlands across breeding range, and general destruction of coastal marshes on wintering grounds, mainly in E China. Breeding area in E Mongolia threatened by droughts and overgrazing.
Bibliography. Alström *et al.* (2008), Anon. (2010c), Brazil (1991, 2009), Butchart & Stattersfield (2004), Byers, Olsson & Curson (1995), Cheng Tsohsin (1987), Dementiev *et al.* (1954, 1970), Eda (1995), Flint *et al.* (1984), Gamova (2003a, 2003b), Jahn (1942), Kanouchi *et al.* (1998), Knystautas & Liutkus (1984), Knystautas & Sibnev (1987), MacKinnon & Phillipps (2000), Maki & Onishi (2000), Nakamura (1981a, 1981b), Nakamura, Iijima & Kagawa (1968), Nakamura, Iijima & Ushiyama (1970), Nazarov (1974), Nishide (1987), Redkin & Koblik (2001b), Shegolev (1974), Sodhi & Nagata (1996), Sodhi *et al.* (1996), Stattersfield & Capper (2000), Šulpin (1931), Takano *et al.* (2001), Tomek (2002), Toru *et al.* (1970).



48. Reed Bunting

Emberiza schoeniclus

French: Bruant des roseaux **German**: Rohrammer **Spanish**: Escribano Palustre
Other common names: Common/Northern Reed Bunting ("northern group"); Dark Reed Bunting (*witherbyi*, *intermedia*, *tschusii*, *reiseri* and *caspia*); Pale Reed Bunting (*pyrrhuloides*, *harterti*, *centralasiae* and *zaidamensis*)

Taxonomy. *Fringilla schoeniclus* Linnaeus, 1758, Sweden.
This species, together with *E. pallasi* and *E. yessoensis*, sometimes placed in genus *Schoeniclus*. Recent molecular study indicates that it is a sister-species to *E. pallasi*, with *E. yessoensis* as sister to both. Race *minor* sometimes included in *E. pallasi*. Geographical variation complex and considerable within wide range; broadly, N races are smaller, with thinner bill, and S races larger, with thicker bill with strongly curved culmen, also clinal variation evident, birds becoming paler from W to E of species' range. For convenience, races can be divided into four groups, i.e. "northern group" (nominate, *lusitanica*, *passerina*, *parvirostris*), "eastern group" (*pyrrhulina*, *minor*), "intermediate group" (*stresemanni*, *ukrainae*, *incognita*, *pallidior*), and "southern group" (*witherbyi*, *intermedia*, *tschusii*, *reiseri*, *caspia*, *korejewi*, *pyrrhuloides*, *harterti*, *centralasiae*, *zaidamensis*); these perhaps represent more than one species, e.g. in N Italy apparent lack of interbreeding between thin-billed nominate race and thick-billed *intermedia* where the two meet, and clear (though weak) degree of genetic differentiation detected between them. Almost 40 races described, some representing points along a cline, others based on trivial differences, and these considered not to merit recognition. In addition, contradictory statements in the literature and, in some cases, inadequate information make delimitation of races difficult; ranges and descriptions given below are provisional and to some extent tentative, and should be treated with a degree of caution. Other proposed races include *goplanae* (described from Warsaw, in Poland), *mackenziei* (from South Uist, in Outer Hebrides) and *turonensis* (from Mézières en Brenne, in Indre department of C France), all synonymized with nominate, and *pallidissima* (from Verkhy Karelina, in upper R Nizhnyaya Tunguska, and Olekminsk, in WC Siberia) treated as synonym of *parvirostris*. Thorough review required. Twenty subspecies currently recognized.
Subspecies and Distribution.
E. s. schoeniclus (Linnaeus, 1758) – breeds Europe from Scandinavia E to Pechora Basin and Urals, S to British Is, most of France, W Austria, N Italy, and across SW Russia; winters S to N Africa and SW Asia.
E. s. passerina Pallas, 1771 – breeds NW Siberia from lower R Ob E to lower R Yenisey and lower R Khatanga (in Taymyr); winters in S Asia E to N India and W China.
E. s. parvirostris Buturlin, 1910 – breeds C Siberia (E to C Yakutia); winters in NW & N China.
E. s. pyrrhulina (Swinhoe, 1876) – breeds E Siberia (Kamchatka) and N Japan (Hokkaido); winters in C Japan, Korea and E China.
E. s. minor Middendorff, 1853 – breeds Transbaikalia E to Russian Far East and NE China (Heilongjiang); winters in E China.
E. s. stresemanni F. Steinbacher, 1930 – E Austria, Hungary and N Serbia.
E. s. ukrainae (Zarudny, 1917) – Ukraine and adjacent SW Russia.
E. s. incognita (Zarudny, 1917) – SE European Russia E to N Kazakhstan.
E. s. pallidior E. J. O. Hartert, 1904 – breeds SW Siberia (in basins of R Tobol and R Irtysh) E to L Baikal; winters in SW & SC Asia.

E. s. witherbyi von Jordans, 1923 – Mediterranean coast of France, Sardinia, Balearic Is, Spain (except NW) and N Africa (NW Morocco).
E. s. lusitanica F. Steinbacher, 1930 – NW Spain and Portugal.
E. s. intermedia Degland, 1849 – Italy and Adriatic coast S to NW Albania.
E. s. tschusii Reiser & Almásy, 1898 – R Danube in Bulgaria and Romania, and in N Black Sea region and Sea of Azov coast.
E. s. reiseri E. J. O. Hartert, 1904 – SE Albania, NW Greece, S Macedonia and W & C Turkey.
E. s. caspia Ménétriés, 1832 – E Turkey E to E Transcaucasia and N & NW Iran, possibly also in Syria.
E. s. korejewi (Zarudny, 1907) – SW & SE Iran and S Turkmenistan.
E. s. pyrrhuloides Pallas, 1811 – breeds N Caspian Sea region (from R Terek) E to W Mongolia, L Balkhash (SE Kazakhstan) and C Tien Shan; non-breeding also to SW & C Asia.
E. s. harterti Sushkin, 1906 – extreme S Russia (S Tuva), extreme E Kazakhstan and extreme NW China (NW Xinjiang).
E. s. centralasiae E. J. O. Hartert, 1904 – Tarim Basin E to Lop Nur, in Xinjiang (W China).
E. s. zaidamensis Portenko, 1929 – Zaidam Depression, in NW Qinghai (W China).

Descriptive notes. 14–16·5 cm; 10–28 g (C Europe). Small to medium-sized or rather large bunting, variable both in body size and in bill size. Male nominate race breeding is distinctive, has blackish head and throat, with prominent white submoustachial stripe and white hindneck-collar meeting on lower neck side; mantle grey-brown mixed with rufous and heavily streaked blackish, scapulars blackish with rufous feather edges, back and rump greyish with dark streaks, uppertail-coverts browner; tail blackish-brown, central feather pair paler, outermost pair with extensive white, adjacent pair with smaller white area; lesser upperwing-coverts red-brown, median and greater coverts blackish-brown with rufous-brown tips, flight-feathers blackish-brown, tertials with rufous edges, primaries and secondaries with narrow pale buffish edges, edges on secondaries brighter and more rufous; underparts dirty white, variable indistinct streaking on side of breast and flanks; iris dark chestnut-brown; bill relatively small, culmen almost straight, blackish; legs brown. Male non-breeding has head pattern largely obscured by grey-brown fringes of new feathers, has buffish supercilium, pale brown lores and ear-coverts, darker brown eyestripe, moustachial stripe and rear edge of ear-coverts, also submoustachial stripe present but not so cleanly white, chin buffish, black malar stripe, throat whitish; nape grey-brown (giving hint of pattern to be acquired during breeding), upperparts, wing and tail much as when breeding, but upperparts somewhat paler; underparts whitish, breast and flanks tinged yellow-buff and streaked brownish; lower mandible blue-grey. First-winter male is almost identical to male non-breeding, except for subtle details, such as more worn wing feathers (not yet moulted), more pointed outer rectrices; iris dark grey-brown. Female breeding is rather similar to male non-breeding, but with nape pale grey-brown to whitish; malar stripe prominent, broader at base than on male non-breeding, breast and flanks distinctly streaked dark, bill blackish. Female non-breeding and first-winter female are very like male in corresponding plumages, except for subtle differences in pattern of crown feathers. Juvenile resembles female, but has chestnut crown with abundance of dark streaks, broader blackish malar stripe, yellowish-buff upperparts streaked and spotted dark, breast heavily streaked and belly and flanks spotted; iris dark grey-brown. Races differ mainly in size and bill size, also in details of plumage, but variation not well understood: *lusitanica* is darkest race, otherwise similar to nominate; *passerina* is paler above and with narrower streaks above and below than nominate; *parvirostris* is small and rather pale, with reduced streaking above, few or no streaks on flanks; *pyrrhulina* is slightly bigger and paler than last, with comparatively large bill with convex culmen; *minor* is very like previous; *stresemanni* is similar to nominate, but with heavier bill, slightly paler rump; *ukrainae* is stronger-billed and paler than nominate; *incognita* is very pale like *pyrrhuloides*, but somewhat greyer above, with smaller bill; *pallidior* also is very pale, like last, but smaller in size and with smaller bill; *witherbyi* is large, with large bill, very dark plumage; *intermedia* is similar to previous, but somewhat smaller; *tschusii* is medium-sized, paler than nominate (especially on rump) and more narrowly streaked above; *reiseri* is large and very dark, with comparatively huge bill; *caspia* is similarly large, but rather pale (close to *intermedia*), with bill comparatively large; *korejewi* is similar to *pyrrhuloides*, perhaps larger-billed, but plumage somewhat darker; *pyrrhuloides*, is large and large-billed, with plumage noticeably very pale, almost greyish-white above; *harterti* is very like previous, but perhaps a little smaller; *centralasiae* also is very similar, but on average smaller; *zaidamensis* is large, about the same as *pyrrhuloides*, but plumage distinctly more buffish (less grey), no streaks below. Voice. Song, from top of bush or reeds, normally a short series of repetitive units, delivered as brief and simple verse, e.g. "sripp srip srriia srrissriisrii" or "zrrit zrrit zrrit zrrururu". Normal contact call a characteristic "siuu", falling in pitch; on migration a "brzii" given by birds in flight.

Habitat. Generally in marshy areas where areas of scrubby growth around reeds, and in areas of tall herbage near wetlands: fens, bogs, riversides and inland waters. In general, associated with humid soils where are dense types of vegetation grow. In Siberia breeds in willow (*Salix*) thickets in floodplains along forest-tundra, but avoids taiga zone. During winter found in similar types of habitat, and also in open fields, cultivations and agricultural areas, in woodland clearings and in weedy areas, often away from water. Will visit gardens in some areas, e.g. parts of Europe. Mostly in lowlands.

Food and Feeding. During breeding season mostly invertebrates; diet otherwise mainly seeds and other plant material. Large-billed races mostly insectivorous all year. In W Palearctic, invertebrates recorded as eaten are springtails (Collembola), mayflies (Ephemeroptera), adult and larval damselflies and dragonflies (Odonata), stoneflies (Plecoptera), grasshoppers and allies (Orthoptera), bugs (Hemiptera), lacewings (Neuroptera), adult and larval Lepidoptera, caddis flies (Trichoptera), adult and larval flies (Diptera), ants (Formicidae), beetles (Coleoptera), spiders (Araneae), harvestmen (Opiliones), ticks (Acari), crustaceans, snails (Pulmonata), bivalve molluscs (of family Sphaeriidae); among plants taken are seeds or other parts of spruce (*Picea*), birch (*Betula*), alder (*Alnus*), nettle (*Urtica*), knotgrass (*Polygonum*), dock (*Rumex*), orache (*Atriplex*), goosefoot (*Chenopodium*), amaranth (*Amaranthus*), chickweed (*Stellaria*), mouse-ear (*Cerastium*), buttercup (*Ranunculus*), rape and allies (*Brassica*), shepherd's-purse (*Capsella*), gold-of-pleasure (*Camelina*), pennycress (*Thlaspi*), meadowsweet (*Filipendula*), lupin (*Lupinus*), flax (*Linum*), willowherb (*Epilobium*), cowberry (*Vaccinium*), scarlet pimpernel (*Anagallis*), forget-me-not (*Myosotis*), basil (*Clinopodium*), potato (*Solanum*), plantain (*Plantago*), mugwort (*Artemisia*), bur-marigold (*Bidens*), hawk's-beard (*Crepis*), sow-thistle (*Sonchus*), *Galinsoga*, mare's-tail (*Hippuris*), water-plantain (*Alisma*), sedges (Cyperaceae), rushes (Juncaceae), reedmace (*Typha*) and grasses (Poaceae). Forages mostly on ground, also in low vegetation. In winter large-billed races extract invertebrates from inside reed stems, a foraging technique that allows them to remain in areas where winter temperatures can drop to below minus 30°C. Singly and in pairs when breeding; at other times in small groups and loose flocks of up to c. 200 individuals, occasionally more.

Breeding. Season early Apr to end Aug, depending on latitude and altitude; in European Russia eggs laid late Jun to early Jul, and in Siberia and Mongolia from beginning Jun and during whole of Jul, whereas in S latitudes breeding begins Apr and lasts sometimes to Aug; up to three broods in S of range. Monogamous; polygyny recorded in some areas. Nest built entirely by female, using twigs, grass, sedges, moss, and reed stems and leaves, lined with finer stems of plants, reed flowers, moss, rootlets and hair, e.g. wild boar (*Sus scrofa*) hair, normally placed on ground, on tussock or on base of a shrub, sometimes up to 4 m above ground in shrub. Clutch 4–5 eggs, olive-grey to pale purple, sparsely marked with dark spots and some fine lines; incubation by both sexes, period 12–15 days; chicks fed by both parents, nestling period 9–12 days.

Movements. Those breeding in S of range resident, or making only short movements. Populations in N, from Scandinavia and Poland E across Russia to Kamchatka and N Japan and, in S, to Ukraine, N Kazakhstan and China almost entirely migratory, although some remain in breeding areas (especially when winters less harsh). In W Europe, most individuals breeding in areas with mean Jan temperature below 0°C are migratory, and those breeding where it is 5°C or above are mostly sedentary; movement may be linked with probability of snowfall and consequent lack of access to seeds on ground (rather than temperature itself), since in N Black Sea region and in C Asia, where precipitation less common, average winter temperature is below freezing but the species remains during winter. Main period of autumn passage during mid-Sept to mid-Nov. Migrants winter in Britain and Ireland, most of continental Europe, N Africa, Mediterranean islands, Turkey, Asia Minor, Levant, S Ukraine and S European Russia, Transcaucasia, Iraq, and N Iran E to Pakistan and NW India; in E, main wintering areas in China (especially N & E) and C & S Japan (N Honshu S to S Kyushu, rarely reaching Ryukyu Archipelago S to Miyako Is), rarely S Korea. Ring recoveries in W Europe suggest differential migration, more females than males moving S. Migration N to breeding areas begins as early as Feb, and is stronger during Mar, and in Apr only late individuals still on wintering grounds; passage in Siberia mainly during May to early Jun. Recorded as vagrant in Iceland, Svalbard, Egypt, Kuwait, UAE, Nepal, Taiwan, Hong Kong and Alaska.

Status and Conservation. Not globally threatened. Generally common or locally common. Estimated European population towards end of 20th century a minimum of 4,800,000 pairs, with largest concentrations in Sweden (650,000), Poland (530,000), Norway (420,000), Germany (400,000) and European Russia (316,000); was thought to be stable during 1970–1990. Declines reported in, especially, Norway and Sweden during 1990–2000, and German population estimated in 2005 to number 300,000–380,000 pairs; populations across most of Europe, including key ones in Russia and Romania, appeared to be stable. Nevertheless, trends in European monitored populations reveal a moderate decline since 1980; moreover, some races evidently giving cause for concern, e.g. both *witherbyi* and *lusitanica* classified in Spain as "endangered". No quantitative data available for Asian part of range, where the species appears to be locally common.

Bibliography. PLATE 45 ➤

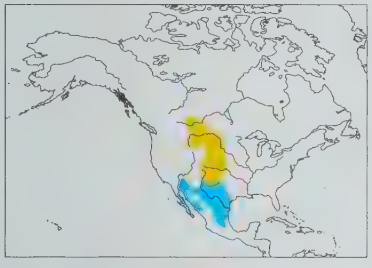
PLATE 45

inches 3
cm 8



Genus *CALAMOSPIZA* Bonaparte, 1838

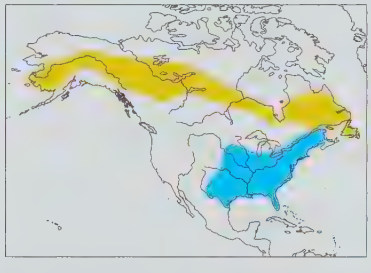
49. Lark Bunting

Calamospiza melanocorys

French: Bruant noir et blanc **German**: Prärieammer **Spanish**: Chingolo Albinegro

Taxonomy. *Calamospiza melanocorys* Stejneger, 1885, plains of Platte River = Nebraska, USA.
Genus perhaps close to *Chondestes*, and in a clade that includes also *Amphispiza* and *Spizella*. Plumage dichromatism and elaborate aerial displays reminiscent of *Calcarius ornatus* and *Rhynchophanes*, but apparently not closely related. Monotypic.
Distribution. Breeds S Canada (S Alberta E to SW Manitoba) and S in Great Plains of USA (E to W Minnesota) to SE New Mexico, N Texas, W Oklahoma and C Kansas; has bred in wet years in E California. Non-breeding from SE Utah and S Arizona E to SW Kansas, W Oklahoma and C & W Texas, S in Mexico to S Baja California, N Sinaloa, Coahuila (uncommon), NE Jalisco and C Tamaulipas.

Descriptive notes. 14–18 cm; 29·5–51·5 g. A large sparrow with large, conical bill and relatively short, notched tail. Male breeding is mostly black, sometimes flecked with white on belly; primaries black, narrowly edged white, secondaries white-tipped, tertials boldly edged white; lesser upperwing-coverts black, median coverts white with variable extent of black at base, greater coverts mostly white, the inner ones black with white outer web or fringes; outer web of lateral rectrices white, inner webs of outer five pairs of rectrices tipped white; iris reddish-brown to black; bill dark bluish or black; legs dull pinkish, usually with darker, greyer feet. Male non-breeding resembles female, but wing blackish and with large whitish patch (as in breeding plumage), ear-coverts blackish, throat black with few pale streaks, underparts more heavily marked with darker, blackish streaking; bill bluish. Female has brown crown and nape streaked darker brown, pale supercilium and lores, brown ear-coverts paler in centre and with pale spot at rear edge; thin moustachial stripe and broad malar stripe dark brown, submoustachial stripe and throat pale brown to buffish-white; upperparts brown, streaked darker brown; tail brown, all except central pair of rectrices tipped dull white, especially on inner webs; upperwing dark brown, median and greater coverts with broad pale buff to white edges and tips (forming paler wing patch, smaller than male's), tertials broadly edged buff to pale white; underparts whitish with sandy brown tinge on sides and flanks, broadly streaked darker brown, undertail-coverts with dark brown centres. Juvenile is similar to female, but with yellowish cast and broad buffy edges on feathers of neck, back and scapulars, giving scaly impression, large pale buffy patch evident on wing. VOICE. Song, often in flight, a musical mixture of short notes and slurred phrases, "kazee kazee kazee kazee, zizizizi zoo quit quit quitquit too wewewewewewew tur tur quit quit quit quit" or "sweet sweet sweet sweet toot toot toot toot toot chug chug chug tr-r-r-r-r". Call a gentle "who-tee-ee", "whee-ta-wer" or "hoo-ee".
Habitat. Short-grass prairie with bare ground and sparse, scattered shrubs e.g. sagebrush (*Artemisia*), also stubble fields and alfalfa (*Medicago*). In non-breeding season found in dry weedy fields, desert scrub and open farmland; often visits cattle-feed lots. Sea-level to high plains.
Food and Feeding. Diet in summer more than 60% animal items, especially short-horned grasshoppers (Acrididae) and beetles (Coleoptera), particularly scarabs and chafers (Scarabaeidae) and weevils (Curculionidae), also other rather small insects, including ants (Formicidae), as well as spiders (Araneae); plant foods consist of seeds of oats (*Avena*), Indian ricegrass (*Oryzopsis*), smartweed (*Polygonum*), buffalo grass (*Bouteloua dactyloides*), sunflowers (*Helianthus*), three-awn grass (*Aristida*), etc. Winter diet not well known; probably mostly seeds, and, when available, takes insects. Forages principally on or near ground or low in vegetation. Typically in small groups; in non-breeding season in flocks, often very large ones.
Breeding. Nest-building and egg-laying from early to middle of May in S part of range and late May in N, but can be delayed by up to two weeks in years with cold spring; very rarely lays second clutch within a season. Monogamous, occasionally polygynous. Male performs stiff-winged display-flight with song. Nest constructed by female alone, taking 2 days, loose in structure, made from dry grass, rootlets and alfalfa stalks, lined with fine grasses and hair, placed on ground underneath shrub or other taller vegetation. Clutch 2–5 eggs, commonly 4, unmarked and with colour ranging from whitish-blue to greenish or greenish-blue; incubation strictly by female, period 12 days; young leave nest at 8–9 days of age, when still cannot fly. Nests sometimes parasitized by Brown-headed Cowbird (*Molothrus ater*), but frequency very low.
Movements. Migratory; routes largely through Great Plains and S Canadian Prairies. Earliest N departures from Mexican wintering grounds occur in Feb, in Sonora some remain into Apr, rarely into May; arrival in Texas may be as early as early Mar, but numbers increase in late Apr and peak in first two weeks May; at N edge of US range and in Canada arrival in late May. Males arrive on territory approximately a week earlier than females. Adult males migrate S earlier than females or young, and adult females appear to move S generally earlier than immatures. In Arizona migrants found as early as Jul, sometimes in good numbers by late Jul, but departure from S Canada (Alberta) does not begin until late Jul and early Aug, suggesting that N populations migrate later; at Big Bend (Texas) migration peaks in early Sept, although first arrivals in early Aug; in much of breeding range migration over by late Sept. Arrival on wintering grounds of Sonora, in Mexico, by early Aug, with larger flocks visible by mid-Aug. A decidedly later spring migrant and earlier autumn migrant than *Calcarius*. Vagrant on W coast in both seasons, more often in autumn; coastal records more likely in autumn, spring records often farther inland, or farther N (British Columbia). Vagrants E of regular range both in spring and in autumn; recorded in most states/provinces in E, predominantly as vagrant in coastal sites.
Status and Conservation. Not globally threatened. Classified as "Declining" in the USA (Yellow WatchList priority species for conservation). Often common or very common in appropriate habitat. Distribution varies annually according to rainfall; in USA, has bred in E California in wet years. Has suffered loss, fragmentation and degradation of habitat owing to conversion of grasslands to agriculture; overgrazing by cattle in short-grass prairies, and absence of natural fire regimes and herbivores, also pose problems; in addition, is vulnerable to poisoning by pesticides (especially diazinon, used for controlling grasshoppers). Nevertheless, despite declines, this species remains numerous in most parts of range.
Bibliography. Adams, Skagen & Adams (2001), Adams, Skagen & Savidge (2007), Armani (1985), Beadle & Rising (2002), Bradshaw (1934), Chaine & Lyon (2008a, 2008b), Harper (1958), Hellmayr (1938), Howell & Webb (1995), Lebbin *et al.* (2010), Miller *et al.* (1957), Nero (1983), Pleszczynska (1978), Pyle (1997), Ridgway (1901), Rising & Beadle (1996), Russell & Monson (1998), Sealy (1999), Shane (2000), Shane & Seltman (1995), Urban (1959), Wilson (1976).



Genus *PASSERELLA* Swainson, 1837

50. Red Fox-sparrow

Passerella iliaca

French: Bruant fauve **German**: Fuchsammer **Spanish**: Chingolo Zorruno

Taxonomy. *Fringilla iliaca* Merrem, 1786, North America = Quebec, Canada.
Genus sometimes subsumed in *Zonotrichia*. This species and *P. schistacea*, *P. megarhyncha* and *P. unalaschcensis* are often treated as conspecific. Some molecular data suggest that *P. arborea* may be sister-taxon of these four. Probably hybridizes occasionally with *P. unalaschcensis* near L Iliamna, at E end of Alaska Peninsula. Geographical variation largely clinal, making delimitation of races difficult; nominate race and *zaboria* intergrade into each other, and many individuals cannot safely be assigned to either race. Two subspecies recognized.
Subspecies and Distribution.
P. i. zaboria Oberholser, 1946 – breeds NW and interior Alaska and in W Canada from N Yukon and NW & CE Northwest Territories E to N Manitoba, S to N British Columbia, C Alberta, C Saskatchewan and S Manitoba; winters in SE USA chiefly E of Great Plains, from E Kansas and S Iowa S to S Texas, Louisiana, Mississippi, Alabama and N Georgia.
P. i. iliaca (Merrem, 1786) – breeds in E Canada from NE Manitoba E to N Labrador, S to NC Ontario, SE Quebec and S Newfoundland; winters in SE Canada (S Ontario and New Brunswick) and E USA from S Wisconsin and S Michigan E to N Vermont, S to S Mississippi, Alabama and C Florida.

Descriptive notes. 15–17 cm; 29·6–49 g. Large sparrow with long wings and relatively short tail. Nominate race has top of head grey with bright rusty-chestnut streaks, grey supercilium, whiter before eye, ear-coverts mixed buff or whitish, rufous and grey, bold moustachial stripe rusty or brownish rusty, submoustachial stripe white with rufous streaking, malar stripe rusty; upperparts grey, mantle and upper back with rusty streaking, lower rump and uppertail-coverts bright rufous; tail rusty, feathers with browner tips; upperwing blackish, most feathers with broad rufous edges, greater and median coverts with narrow whitish tips (indistinct pale wingbars); throat creamy white; underparts white, breast and flanks heavily streaked reddish-brown, streaks becoming small chevrons on lower breast; iris dark red-brown; upper mandible mostly dark greyish-horn, lower mandible mostly yellow; legs pink. Sexes similar. Juvenile has crown and back brown, centres of feathers dark brown or rusty brown, upperwing-coverts and tertials broadly edged rusty, underparts paler and streaked; moults before migrating. Race *zaboria* lacks streaks on crown or has only faint dull reddish-brown marks, back more faintly streaked than nominate, underparts less streaked/spotted and spotting not so brightly reddish-brown. VOICE. Primary song a series of loud, clear, slurred ringing whistles on different pitches, usually ending with buzzy whistle, often sounding rather like "aujourd'hui"; female occasionally sings; occasionally sings in winter. Contact call a faint "tsip"; alarm a loud "smack", "tchek" or "chick".
Habitat. Breeds in dense deciduous thickets, commonly alders (*Alnus*) or willows (*Salix*), in bogs, and dwarf spruce (*Picea*), balsam fir (*Abies balsamea*) or tamarack (*Larix laricina*). On migration and in winter generally in low, moist areas with rank, tall brush, and brush piles, often at woodland edge, streamside thickets, or in wet woods.
Food and Feeding. During breeding season a wide variety of arthropods, including beetles (Coleoptera), fly larvae (Diptera), caterpillars (Lepidoptera), ants (Formicidae) and bees (Apoidea), scale insects (Coccoidea), spiders (Araneae) and millipedes (Diplopoda), as well as small molluscs (Bivalvia and Gastropoda), also seeds, berries (*Amelanchier*); will take dead fish. In winter, feeds on variety of fruits, seeds and buds. Forages on ground and low in vegetation. Often uses both feet together to scratch in litter, thereby exposing concealed prey. Singly and in small groups; in non-breeding season often in flocks with other sparrow species, and occasionally forms large flocks.
Breeding. Season early Apr through early Jul; in Newfoundland egg-laying commences as early as late Apr, most clutches begun in May and early Jun, few not until Jul, and some juveniles fledge in early Jun; single-brooded. Apparently monogamous, but details of mating poorly known. On arrival in breeding area, male quickly begins territorial defence, and pair formation occurs within a week; territory size in Newfoundland 0·25–1 ha. Nest built from dry grass, twigs, moss or bark, lining of finer grasses, moss, lichens, feathers and hair, placed on ground, or usually below 1·5 m above ground in bush or tree, most nests in Newfoundland under conifer. Clutch 2–4 eggs, usually 3, ground colour variable, tends to be pale bluish or greenish, with brownish or rusty spots and scrawls, particularly concentrated at large end; incubation by female, period 12–14 days; nestling period 10–11 days. Nests (of race *zaboria*) parasitized extremely rarely by Brown-headed Cowbird (*Molothrus ater*).
Movements. Migratory. Most winter E of Great Plains; uncommon on W coast and in S Arizona and New Mexico. Ringing studies reveal average migration distance between breeding and wintering sites to be c. 1100 km. Those breeding in Maritime Provinces winter along mid-Atlantic coast of USA, those from farther W winter largely in SE USA. A late autumn migrant and early migrant in spring. Leaves breeding grounds from Sept, arriving Great Lakes region by middle to late Sept;

On following pages: 51. Slate-colored Fox-sparrow (*Passerella schistacea*); 52. Thick-billed Fox-sparrow (*Passerella megarhyncha*); 53. Sooty Fox-sparrow (*Passerella unalaschcensis*); 54. American Tree Sparrow (*Passerella arborea*); 55. Volcano Junco (*Junco vulcani*); 56. Yellow-eyed Junco (*Junco phaeonotus*); 57. Dark-eyed Junco (*Junco hyemalis*).

arrival in wintering areas in Texas and Louisiana in second half Oct. Departure from wintering grounds by late Mar, although rarely some hang on much later, until early May. Spring arrival in Great Lakes area early Mar, and most have moved through by late Apr; farther N & E, in Newfoundland, arrival in early Apr. Rare vagrant on Pacific coast, most apparently of race *zaboria*; nominate race recorded rarely W to Colorado and S to S Florida. Accidental to Greenland, Iceland, Northern Ireland, Germany (possibly ship-assisted) and Italy.

Status and Conservation. Not globally threatened. Fairly common throughout range in suitable habitat. Breeds in fairly remote areas that have been little disturbed by humans, and wintering habitat also has been little affected by human activities. No indication that this species' numbers are in decline.

Bibliography. Armani (1985), Beadle & Rising (2002), Bent & Austin (1968), Brewer *et al.* (2000), Garrett *et al.* (2000), Glutz von Blotzheim & Bauer (1997), Koblik *et al.* (2006), Lewington *et al.* (1991), McCarthy (2006), Pyle (1997), Ridgway (1901), Rising (1995), Rising & Beadle (1996), Ryan (1974), Swarth (1920), Threlfall & Blacquiere (1982), Wacker *et al.* (2010), Weckstein *et al.* (2002), Williamson & Peyton (1962), Zink (1986, 1991, 1994, 2008).

51. Slate-colored Fox-sparrow

Passerella schistacea

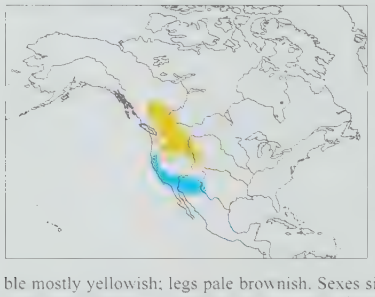
French: Bruant ardoisé **German**: Schieferammer **Spanish**: Chingolo Pizarroso

Taxonomy. *Passerella schistacea* S. F. Baird, 1858, "Head of the Platte" = south fork of Platte River, about 25 miles [c. 40 km] east of north-eastern corner of Colorado, in Nebraska, USA.

Genus sometimes subsumed in *Zonotrichia*. This species and *P. iliaca*, *P. megarhyncha* and *P. unalaschcensis* are often treated as conspecific. Some molecular data suggest that *P. arborea* may be sister-taxon of these four. Race *altivagans* sometimes treated as a race of *P. iliaca*; looks similar to race *zaboria* of latter and also to *P. unalaschcensis*, probably reflecting low-level introgression with both species, though molecular-genetic studies suggest that frequency of such interbreeding is low. Race *fulva* sometimes placed in *P. megarhyncha*. Six subspecies recognized.

Subspecies and Distribution.

P. s. olivacea Aldrich, 1943 – breeds SW Canada (SC & SW British Columbia) S to NW USA (C & E Washington); non-breeding in SW USA (interior California) and extreme NW Mexico (N Baja California).



P. s. altivagans Riley, 1911 – breeds in interior C & SE British Columbia and SW Alberta; non-breeding principally SW USA (Cascades and Sierra Nevada, in California, and SW Arizona) and extreme NW Mexico (NW Baja California).

P. s. schistacea S. F. Baird, 1858 – breeds extreme S Canada (extreme SE British Columbia and SC Alberta) S in USA through NC & E Oregon and N Idaho to NC & NE Nevada, E to W Montana, SW Wyoming and C Colorado; non-breeding in interior of N California, C Arizona and N New Mexico S to N Baja California, S Arizona and W Texas.

P. s. swarthi Behle & Selander, 1951 – breeds W USA (SE Idaho and NW Utah).

P. s. fulva Swarth, 1918 – breeds W USA (E side of Cascade Range in C Oregon S to Modoc Plateau, in NE California); non-breeding in SW California and N Baja California.

P. s. canescens Swarth, 1918 – breeds C Nevada and extreme CE California (White Mts); non-breeding in S California, N Baja California and S Arizona.

Descriptive notes. 15–18 cm; 26–35 g. Large sparrow with relatively long tail. Nominate race has head slate-coloured, pale lores, whitish submoustachial stripe with dark streaks; upperparts grey, washed brown, lower rump and tail rusty brown; upperwing black, most feathers broadly edged rufous, greater and median coverts sometimes with very narrow whitish tips (indistinct pale wingbars); throat and underparts white, breast and flanks heavily marked with blackish arrowhead-shaped spots, these becoming smaller and browner posteriorly; iris dark red-brown; upper mandible mostly dark greyish-horn, lower mandible mostly yellowish; legs pale brownish. Sexes similar. Juvenile resembles adult, but upperparts more distinctly tinged with brown; moults before migrating. Races differ minimally: *olivacea* is relatively small, with crown and back uniformly greyish-olive with reddish tinge; *swarthi* has crown uniformly darker greyish-olive, and heavy brown spots on breast and belly; *fulva* is similar to previous, but bill larger; *canescens* is small, with relatively small bill, and with crown and back uniformly pale grey; *altivagans* is browner above than others, mantle and back slightly streaked rusty, malar stripe and markings below browner with slight rusty tinge. Voice. Song clear and ringing, starting with 2–3 syllables on different pitches, "too-wheet-whoo tweek-tsuck-tseeka tsew!", with alternate notes emphasized; several elements may have buzzy quality, and many incorporate short warbles; individuals may have 2–5 different songs, not singing same twice in a row. Call a distinctive metallic "chink", "chek" or "klink", or faint "seet".

Habitat. Breeds in impenetrable riparian thickets of mountain meadows, with alder (*Alnus*), water birch (*Betula occidentalis*), willows (*Salix*), currants and gooseberries (*Ribes*), and roses (*Rosa*); in SE British Columbia and SW Alberta in dense clumps of alpine dwarf spruce (*Picea*). Mainly in wooded habitats with dense understorey in non-breeding season.

Food and Feeding. In breeding season primarily insects, e.g. beetles (Coleoptera), probably also other invertebrates, seeds and berries when available. In winter, probably a variety of fruits, seeds and buds, and when available insects. Forages on ground or low in vegetation.

Breeding. Season mid-May to mid-Jul; probably single-brooded. Probably monogamous. Nest construction requires two days; nest made from dry grass, twigs, moss or bark, lining of finer grasses, moss, lichens, feathers and hair. Clutch variable, typically 5 eggs, ground colour variable, tends to be pale bluish or greenish, with brownish or rusty spots and scrawls; incubation period 12–14 days; no information on nestling period. Nests parasitized rarely by Brown-headed Cowbird (*Molothrus ater*).

Movements. Most populations migratory, spending non-breeding season in interior of California, C Arizona and New Mexico S to N Baja California, N Sonora and W Texas; non-breeding range of race *swarthi* not known. S populations may perform altitudinal movements, rather than true migration. Migratory routes little known, but include major river valleys, particularly in spring (when highlands may still be snow-covered), and montane meadows in autumn; all within W mountains of North America. Rare on Pacific coast, although regular in drier scrubby sites immediately E of coastal mountains in C California. Migrates much earlier, both in spring and in autumn, than *P. iliaca*. Arrives on breeding grounds as early as late Mar, and autumn migrants seen as early as late Aug in Arizona and New Mexico. Casual in CS Canada (Manitoba) and W Nebraska.

Status and Conservation. Not globally threatened. Fairly common throughout its range in suitable habitat. No indication of any change or reduction in numbers.

Bibliography. Aldrich (1943), Armani (1985), Beadle & Rising (2002), Garrett *et al.* (2000), McCarthy (2006), Pyle (1997), Ridgway (1901), Rising (1995), Rising & Beadle (1996), Swarth (1920), Weckstein *et al.* (2002), Williamson & Peyton (1962), Zink (1986, 1991, 1994, 2008).

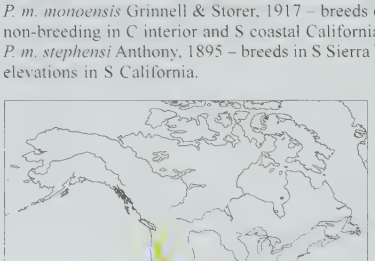
52. Thick-billed Fox-sparrow

Passerella megarhyncha

French: Bruant à bec épais **German**: Dickschnabelammer **Spanish**: Chingolo Picogrueso
Other common names: Large-billed Fox-sparrow

Taxonomy. *Passerella megarhynchus* S. F. Baird, 1858, Fort Tejon, Kern County, California, USA.

Genus sometimes subsumed in *Zonotrichia*. This species and *P. iliaca*, *P. schistacea* and *P. unalaschcensis* are often treated as conspecific. Some molecular data suggest that *P. arborea* may be sister-taxon of these four. Geographical variation very slight; species sometimes treated as monotypic. Proposed race *mariposae* (described from Yosemite Park, in California) included within nominate. Race *fulva* of *P. schistacea* sometimes included in present species. Four subspecies tentatively recognized.



Subspecies and Distribution.

P. m. megarhyncha S. F. Baird, 1858 – breeds W USA from extreme SW Oregon S to CN California (including Sierra Nevada); non-breeding in C & S California S to extreme NW Mexico (NW Baja California).

P. m. brevicauda Mailliard, 1918 – breeds in interior N coast ranges of California S to Colusa County; non-breeding C & S coastal California.

P. m. monoensis Grinnell & Storer, 1917 – breeds on E slope of Sierra Nevada (in EC California); non-breeding in C interior and S coastal California, and NW Baja California.

P. m. stephensi Anthony, 1895 – breeds in S Sierra Nevada (in S California); non-breeding at lower elevations in S California.

Descriptive notes. 15–18 cm; 29–38 g. Large sparrow with large bill and relatively long tail. Nominate race has slate-coloured head and upperparts washed with brown, rump brown, tail rusty brown; submoustachial stripe streaked whitish and black, malar stripe blackish; upperwing mostly reddish-brown; throat and underparts whitish, lower throat to breast and flanks spotted with blackish; iris dark brown; bill steel-grey, with dusky grey culmen (non-breeding, steel-grey replaced with yellowish); legs brownish. Sexes similar. Juvenile resembles adult, but upperparts more distinctly tinged with brown; moults before migrating. Races differ very little, chiefly in bill size: *brevicauda* is similar to nominate, but bill even larger, crown and back uniformly greyish-brown, spotting on breast and belly sparse; *monoensis* has noticeably smaller bill than last; *stephensi* has very large and broad bill, largest bill of all races. Voice. Song clear and ringing, starting with 2–3 syllables on different pitches, "too-wheet-whoo tweek-tsuck-tseeka tsew!", every other note emphasized. Call a distinctive metallic "chink", "chek" or "klink", and faint "seet".

Habitat. Deciduous thickets, sometimes thick, scrubby conifers, generally along streams, brushy fields, burnt forest (c. 10 years after fire) and montane chaparral, especially with greenleaf manzanita (*Arctostaphylos patula*), mountain whitethorn (*Ceanothus cordulatus*) and bush chinquapin (*Castanopsis sempervirens*); 1200–3000 m. In S Sierra Nevada also in elderberry (*Sambucus*) thickets. In winter found in chaparral and streamside thickets, mostly on warmer S-facing slopes dominated by chamise (*Adenostoma fasciculatum*).

Food and Feeding. In breeding season feeds primarily on insects, and probably also on other animal items; will also take seeds and berries when they are available. In winter probably eats variety of fruits, seeds and buds, also insects when these available. Forages on ground or low in vegetation.

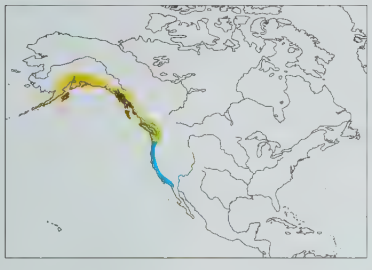
Breeding. Season mid-May to mid-Jul; probably single-brooded. Probably monogamous. Nest built by female, of dry grass, twigs, moss or bark, lined with finer grasses, moss, lichens, feathers and hair, most placed on ground and often concealed by low vegetation, including conifers, oaks (*Quercus*) or *Ceanothus* shrubs, up to 20% of nests may be in low vegetation, often in fork of low branch near ground, but always very well concealed. No information on clutch size, eggs variable, ground colour tends to be pale bluish or greenish, with brownish or rusty spots and scrawls; incubation by female, period 12–14 days; no information on nestling period. Nests parasitized rarely by Brown-headed Cowbird (*Molothrus ater*).

Movements. Most, if not all, populations migratory, some perhaps moving very short distance or performing largely altitudinal movements; more research needed. Migrates earlier than other members of genus. S-bound migration noted from middle to late Aug, majority heading S in Sept; some remain in breeding areas into mid-Sept. Nearly all winter in S California and N Baja California. In spring, N-bound migrants appear in desert oases by mid-Feb, and peak migration late Mar to late Apr.

Status and Conservation. Not globally threatened. Locally common. Little information available on numbers.

Bibliography. Armani (1985), Beadle & Rising (2002), Burns & Hackett (1993), Garrett *et al.* (2000), Mailliard (1921), McCarthy (2006), Pierce (1921), Pyle (1997), Ridgway (1901), Rising (1995), Rising & Beadle (1996), Swarth (1920), Weckstein *et al.* (2002), Williamson & Peyton (1962), Zink (1986, 1991, 1994, 2008).

53. Sooty Fox-sparrow



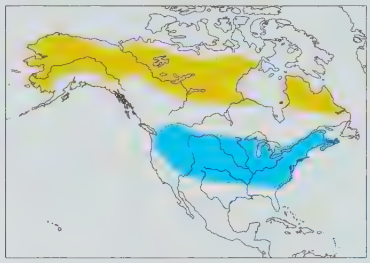
Passerella unalaschcensis

French: Bruant fuligineux **German**: Aleutenammer **Spanish**: Chingolo Fuliginoso

Taxonomy. *Emberiza unalaschcensis* J. F. Gmelin, 1789, Unalaska, Aleutian Islands, Alaska, USA.

Genus sometimes subsumed in *Zonotrichia*. This species and *P. iliaca*, *P. schistacea* and *P. megarhyncha* are often treated as conspecific. Some molecular data suggest that *P. arborea* may be sister-taxon of these four. Nominate race probably hybridizes occasionally with *P. iliaca* near L Iliamna, at E end of Alaska Peninsula. When placed in genus *Zonotrichia*, race name *insularis* invalid, as preoccupied, and replaced by *ridgwayi*. Geographical variation appears to be mainly clinal. Seven subspecies recognized.

Subspecies and Distribution.
P. u. unalaschcensis (J. F. Gmelin, 1789) – breeds from Aleutian Is (E from Unalaska) E, including Shumagin Is and Semidi Is, to Alaska Peninsula; non-breeding from extreme SW Canada (SW British Columbia) S in W USA to California.
P. u. insularis Ridgway, 1900 – breeds in Kodiak Is group, in Alaska; non-breeding coastal S California.
P. u. sinuosa Grinnell, 1910 – breeds Kenai Peninsula and Prince William Sound, and on Middleton I (Alaska); non-breeding from SW British Columbia S to extreme NW Mexico (NW Baja California).
P. u. annectens Ridgway, 1900 – breeds near Yakuatat Bay, in S Alaska; non-breeding from C coastal California (also, less commonly, from SW British Columbia) S to C interior & S California.
P. u. townsendi (Audubon, 1838) – breeds from SE Alaska (including mainland N of R Stikine) S to Queen Charlotte Is (W British Columbia); non-breeding from SE Alaska and S coastal British Columbia S in W USA to coastal N & C California.
P. u. fuliginosa Ridgway, 1899 – breeds from coast of SE Alaska and coastal British Columbia (except Queen Charlotte Is) S to extreme NW USA (NW Washington); non-breeding from SW British Columbia S on coast to C California.
P. u. chilcatensis Webster, 1983 – breeds from R Chilkat area of Alaska SE to Stewart area of British Columbia; non-breeding from coastal Oregon S to N California.

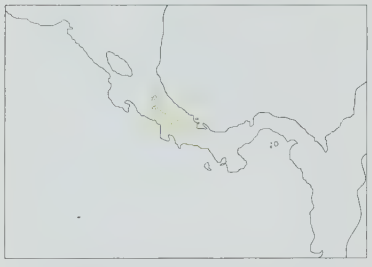


Descriptive notes. 15·5–18·5 cm; 25·3–42·1 g. Large, very dark brown sparrow. Nominate race has most of head uniformly dark grey-brown, a few beige flecks sometimes evident in submoustachial stripe and on lores, weakly defined greyer supercilium and side of neck; moustachial stripe bold rusty or brownish rusty, malar stripe dark brown; upperparts plain dark brown; tail dull rufous-brown to dark brown; upperwing brown or dark brown, hint of rusty colour in scapulars, tertials and wing-coverts; throat pale, heavily spotted or streaked with dark brown; underparts whitish, heavily streaked brown to dark brown; iris dark; bill mostly dusky-grey above, orange-yellow below; legs brownish. Sexes similar. Juvenile is like adult, but pale areas buff or dark buff; moults before migrating. Races differ little, mainly in coloration and to lesser extent in size and bill size, nominate largest and with relatively large bill, and palest: *sinuosa* has thinner bill than nominate, and ashy tinge on side of neck and back; *insularis* somewhat brighter and redder than previous, with buff wash on undertail-coverts; *fuliginosa* is darkest, dark sooty brown to blackish-brown above; *annectens* is smaller than previous and not quite so dark; *townsendi* also is smaller, and is brighter and less sooty than *fuliginosa*; *chilcatensis* blacker than previous but duller than *fuliginosa* and tail shorter. Voice. Song a loud series of rather staccato notes, rising and falling on different pitches, "she she shut u-you tu-you"; many of the notes slurred. Common call a loud "tik", "thick" or sharp "zitt".
Habitat. Breeds especially in dense deciduous thickets, commonly alders (*Alnus*), willows (*Salix*) or blackberry (*Rubus*), often in lush growth along creeks or at edge of bogs and ponds; from beach to timber-line. On migration and in winter generally in low, moist areas with rank, tall brush, and brush piles, often at woodland edge, or in wet woods; in California, in winter, found in chaparral, especially dense arborescent chaparral; in British Columbia, generally in dense understorey.
Food and Feeding. Little information available. During breeding season probably eats wide variety of arthropods, as well as small molluscs (Bivalvia and Gastropoda), seeds and fruit. In winter variety of fruits, seeds and buds no doubt consumed, as well as animal items when these available. Forages on ground and low in vegetation. Often uses both feet together to scratch in litter, thereby exposing concealed prey.
Breeding. Season early Apr to Aug. Apparently monogamous, though courtship poorly known. Nest made from dry grass, twigs, moss or bark, lining of finer grasses, moss, lichens, feathers and hair, placed up to 4 m above ground in bush or low in tree, sometimes on ground. Clutch commonly 4 eggs, variable, ground colour tends to be pale bluish or greenish, with brownish or rusty spots and scrawls; incubation by female, period 12–14 days; no information on nestling period. Nests parasitized extremely rarely by Brown-headed Cowbird (*Molothrus ater*).
Movements. A "leap-frog migrant", populations breeding farther N wintering farther S than more S breeders. S breeders essentially resident or very short-distance migrants. Ringing studies indicate that wintering individuals (in San Jose area of California) return to same site year after year. N populations migrate mostly along Pacific coast, Alaskan populations S (perhaps directly over ocean) to California. Those breeding in Aleutians and Alaska Peninsula (nominate race), Kodiak I (*insularis*) and SW Alaska (*sinuosa*) winter in S California; those from Alaska panhandle (*annectens*) and coastal British Columbia (*townsendii*) winter on coast S to C Oregon; and those breeding on Vancouver I (*fuliginosa*) are apparently non-migratory. Arrival in autumn in C California by early Sept, in S California by mid-Sept, but peak migration pulse in early Oct. N-bound passage in California between late Mar and early Apr, some reaching breeding areas by late Apr/early May. Most winter on Pacific Coast from British Columbia S to N Baja California; casual in SE Arizona. Recorded as accidental in Japan, Pribilofs and St Lawrence I, and at Point Barrow (N Alaska), Nunavut (NC Canada) and North Dakota (N USA); nominate race recorded in Russian Far East (Chukotka, Wrangel I and Commander Is).
Status and Conservation. Not globally threatened. Locally common. This species' preferred habitats seem to have been little affected by recent human activities. No clear evidence of any changes in population sizes.
Bibliography. Armani (1985), Beadle & Rising (2002), Bell (1997), DeSante & Ainley (1980), Garrett *et al.* (2000), Grinnell (1910), McCarthy (2006), Pyle (1997), Ridgway (1901), Rising (1995), Rising & Beadle (1996), Swarth (1920), Wacker *et al.* (2010), Weckstein *et al.* (2002), Williamson & Peyton (1962), Zink (1986, 1991, 1994, 2008).

54. **American Tree Sparrow**
Passerella arborea

French: Bruant hudsonien **German**: Baummammer **Spanish**: Chingolo Arbóreo
Other common names: Tree Sparrow

Taxonomy. *Fringilla arborea* A. Wilson, 1810, eastern Pennsylvania = Philadelphia, USA.
Traditionally placed in genus *Spizella*, which it resembles. Recently published molecular studies suggest that this species is best placed in present genus, possibly as sister to the four other members. Geographical variation weakly marked. Two subspecies tentatively recognized.
Subspecies and Distribution.
P. a. ochracea (Brewster, 1882) – breeds Alaska and in W Canada from N Yukon and NW Northwest Territories S to NW British Columbia and probably NC Alberta; winters in S Canada (W Saskatchewan) and N & W USA from South Dakota and N Iowa S to NE California, W & N Nevada, N Arizona, C New Mexico and C Texas.
P. a. arborea (A. Wilson, 1810) – breeds in NC & E Canada from C & E Northwest Territories and W Nunavut E to Labrador, S to N Saskatchewan, N Manitoba, N Ontario and C Quebec; winters in E USA (from Minnesota, Wisconsin and N Michigan S to Oklahoma, Arkansas, Tennessee, North Carolina and Virginia) and SE Canada (S from C Ontario and SW Quebec, E to New Brunswick and Nova Scotia).



Descriptive notes. 13·5–14·5 cm; 12·6–27·7 g. A slim sparrow with fairly long, notched tail. Nominate race has crown rusty, rusty post-ocular stripe, rest of head grey, indistinct rusty submoustachial line, narrow whitish eyering; upperparts tawny-rufous, mantle and scapulars with blackish streaks, rump and uppertail-coverts grey with olive tinge; tail feathers blackish with narrow pale edges, outermost pair with greyish-white outer web; median and greater upperwing-coverts blackish with broad rufous edges and broad white tips (two wingbars), flight-feathers blackish with narrow pale edges, tertials with broad rufous edges and small white tips; throat whitish; underparts pale grey, side of upper breast rusty, central breast with variable dusky spot, flanks buffy; iris dark red-brown; bill blackish, lower mandible except tip yellow. Sexes similar. Juvenile resembles adult, but streaked brown (perhaps tinged with rusty) on crown, nape and side of neck, and heavily streaked blackish-brown on underparts (except for lower belly); in first autumn resembles adult, but may have streaks on crown. Race *ochracea* averages slightly (but not significantly) larger, and is paler, especially on nape. Voice. Song, in summer often delivered at night, is a clear, sweet and musical "tsee tsee-tsi tsi tsi", with final note lower in pitch. Call "tseet".
Habitat. Breeds in dwarf spruce (*Picea*) and birch (*Betula*) habitat at the edge of the tree-line. During non-breeding season found in hedgerows and urban parks, and in oldfields, down to sea-level.
Food and Feeding. In summer, consumes variety of arthropods and also seeds of alder (*Alnus*), redroot pigweed (*Amaranthus retroflexus*) and mustard (*Brassica*). In winter, appears to feed on seeds of pigweed, common ragweed (*Ambrosia artemisiifolia*), beard grass (*Andropogon virginicus*) and others; also eats beetles (Coleoptera) and other insects and arthropods when these available. Studies suggest that percentage of animal items close to 100% during breeding season, but close to zero in winter. Forages mainly on ground. In winter, individuals forage by scratching in dried grasses. In summer, picks seeds from ground, also gleans insects from bushes, and occasionally makes flycatching sallies for aerial insects.
Breeding. Nest-building begins early to middle Jun, egg-laying mid-Jun to early Jul, fledglings late Jun through early Aug; generally single-brooded. Monogamous. Pair formation occurs on breeding grounds. Nest construction slow, requiring up to 7 days, nest a thick cup made from dry grasses, twigs and moss, lining of finer grasses and ptarmigan (*Lagopus*) feathers, placed on or near ground, usually at base of shrub, tree or grass tussock. Clutch 4–6 eggs, usually 5, pale greenish, blue or even buff or cream, heavily spotted or blotched with dark brown, rusty or purplish; incubation by female, period 10·5–13·5 days; chicks fed by both sexes, nestling period 8–10 days; both parents attend to young.
Movements. Migratory; entire population migrates S, males wintering farther N than females. Migratory routes not well known, most members of W breeding populations appear to move S & E towards Mississippi Valley, rather few winter S along Pacific coast or W mountain region. E populations appear to migrate without much of an E–W component. Departure from wintering grounds begins in late Feb; peak N-bound passage in Mississippi Valley late Mar to early Apr, slightly later, into mid-Apr, in New York. Arrivals on breeding grounds of Churchill (in Manitoba) mainly late May to early Jun, timing depending on snow melt in the particular year; timing of arrival in W breeding areas (in Alaska and Yukon Territory) similarly in late Apr to early May; males arrive shortly before females. S-bound movements from breeding grounds begin early to middle Sept; arrival in S Ontario and N states of USA by early Oct; wintering areas farthest S occupied by early Nov. Non-breeders recorded occasionally S to Rio Grande Delta, W Louisiana, N Alabama, South Carolina and Georgia; race *ochracea* recorded in Russian Far East (Chukotka, Wrangel I and Kamchatka).
Status and Conservation. Not globally threatened. Often common or very common in appropriate habitat throughout most of range. Estimated global population has been put at 10,000,000–20,000,000 pairs.
Bibliography. Anon. (1998), Armani (1985), Baumgartner (1937, 1942, 1968a), Beadle & Rising (2002), Brooks (1985), Dance (1986), Dunning (2008), Graul (1967), Hellmayr (1938), Koblik *et al.* (2006), Naugler (1993), Peck & James (1987), Pyle (1997), Rising & Beadle (1996), West & Peyton (1972), Willoughby (1991).

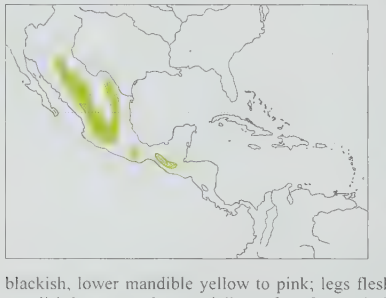
Genus *JUNCO* Wagler, 1831

55. **Volcano Junco**
Junco vulcani

French: Junco des volcans **German**: Streifenwinterammer **Spanish**: Junco de los Volcanes

Taxonomy. *Zonotrichia vulcani* Boucard, 1878, Volcán de Irazú, 10,000 feet [c. 3050 m], Costa Rica.
Molecular data point to close relationship between this genus and *Zonotrichia*. Recent molecular-genetic analyses indicate that present species is basal in genus, its closest relative being race *alticola* of *J. phaeonotus*. Monotypic.
Distribution. Volcanic summits in Costa Rica and W Panama (Volcán de Chiriquí).
Descriptive notes. 15·2–16·6 cm; 28 g (Costa Rica). A large junco with no white in tail. Has crown to upper mantle olive-brown with faint darker streaking, black lores and line behind eye, grey side of head and narrow grey superciliary stripe; lower mantle to uppertail-coverts dull olive-brown, lower mantle, back and scapulars dark-streaked; tail dusky, feathers with narrow greyish edges, outer feathers tipped grey; upperwing blackish-brown, wing-coverts and tertials with wide tawny-brown edges, primaries and secondaries with narrow grey-brown edges; black speckling on chin, throat slightly paler grey than breast, underparts grey with olive-buff tinge, especially on flanks

and vent; iris yellow to golden-yellow; bill pinkish; legs yellowish-pink to brownish-grey. Sexes similar. Juvenile has brown of upperparts more reddish, with more streaking, underparts buff, streaked with brown, except on centre of belly. Voice. Song consists of short, choppy phrases containing squeaky or buzzy notes, e.g. "k'cheew chu k'wee, chip-chip ts'chew tsi'weet". Calls notes a repeated "tchup", also "tsee", "cher-wi" and similar.
Habitat. Open, grassy areas with stunted scrub, second growth, or overgrown pastures, also along roadsides; commonest above treeline. At 2600–3000 m.



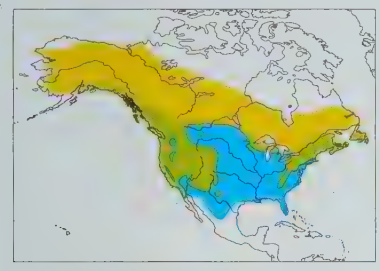
Food and Feeding. Diet seeds and berries; also arthropods, including insects and spiders (Araneae). Forages principally on or near ground or low in vegetation; hops and runs. Usually in pairs.
Breeding. Nest found during Apr, and fledged young observed in May and Jun. One nest described, a cup of dry grasses, lined with fluff from thistle, as well as hair, placed on mossy overgrown embankment, moss overhanging and forming canopy over nest; contained 2 eggs, pale blue, with lilac dots concentrated about large end. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Not common; local. No estimates of global population available; total population cannot be large, and is fragmented. Numbers thought to be stable.
Bibliography. Armani (1985), Barrantes (1994b), Garrigues & Dean (2007), Hellmayr (1938), Milá *et al.* (2007), Miller (1941), Ridgway (1901), Sassi (1939), Stiles & Skutch (1989), Wetmore *et al.* (1984).

56. Yellow-eyed Junco

Junco phaeonotus

French: Junco aux yeux jaunes **German**: Rotrückenammer **Spanish**: Junco Ojilumbre
Other common names: Mexican Junco (*phaeonotus* and *palliatus*); Baird's Junco (*bairdi*); Chiapas Junco (*fulvescens*); Guatemala Junco (*alticola*)

Taxonomy. *Junco phaeonotus* Wagler, 1831, Mexico.
Molecular data indicate close relationship between this genus and *Zonotrichia*. Recent molecular-genetic studies suggest that genus spread quickly N from Central America in post-glacial period; although morphological divergence high, molecular divergence not so well marked; on the other hand, the farther S in Central America, the older is the lineage, and the more distinctly characterized it is molecularly. Present species closely related to *J. vulcani*, but its N populations are genetically very close to *J. hyemalis*; unpublished molecular data suggest that Guadalupe taxon *insularis*, generally included with latter, may be better placed with present species. Races form four groups, one represented by nominate and *palliatus*, the other three being single-subspecies groups formed by, respectively, *bairdi*, *fulvescens* and *alticola*. These sometimes treated as four separate species; indeed, Guatemala population (*alticola*) appears genetically well differentiated from all other taxa in genus, and further work may support its elevation to species rank. Race *palliatus* intergrades with nominate in C Mexico from Nayarit, Durango, Coahuila and Nuevo León S to Guanajuato. Five subspecies recognized.
Subspecies and Distribution.
J. p. palliatus Ridgway, 1885 – mountains of SW USA (S Arizona and extreme SW New Mexico) and NW Mexico from NE Sonora, Chihuahua and Coahuila S to N Jalisco, Guanajuato, San Luis Potosí and NW Tamaulipas.
J. p. phaeonotus Wagler, 1831 – mountains of C & S Mexico from Nayarit, Durango, Coahuila and Nuevo León S to Oaxaca and Veracruz.
J. p. bairdi Ridgway, 1883 – Cape District of S Baja California (W Mexico).
J. p. fulvescens Nelson, 1897 – mountains of interior of Chiapas, in SE Mexico.
J. p. alticola Salvin, 1863 – mountains of SE Chiapas (Mexico) and W Guatemala.



Descriptive notes. 13·5–17·2 cm; 18·3–22 g (Arizona). A medium-sized sparrow, grey and white in coloration, with white in outer tail. Nominate race has head and neck slate-grey, blackish lores; mantle and back bright cinnamon-rufous, rump and uppertail-coverts grey; tail dark grey, outer two feather pairs mostly white; upperwing grey, median coverts and inner greater coverts rufous, flight-feathers blackish with narrow paler edges, tertials with broad rufous edges; chin and throat to breast and flanks pale grey, rear flanks faintly tinged olive-buff, belly and undertail-coverts paler greyish-white; iris yellow; upper mandible blackish, lower mandible yellow to pink; legs flesh-coloured or pinkish, sometimes with darker purplish-brown wash, especially on feet. Sexes similar in colour, male slightly larger than female. Juvenile has thin dark streaking on crown and underparts, some rusty colour on back. Races differ mainly in plumage tones and in extent of white in tail: *palliatus* is paler than nominate, head paler ashy grey, back somewhat brighter, more white in tail; *bairdi* is smaller and paler than others, has less black on face, browner back grading into buffish rump, paler below, flanks warm brown; *fulvescens* is duller than nominate, has dull slate-brown head, olive-brown back, light olive flanks tinged with buff posteriorly, less white in tail; *alticola* is like *fulvescens*, but slightly darker, has even less white in outer rectrices. Voice. Song, typically from perch 3–5 m high or treetop, characteristically consists of two or three parts contrasting in rhythm and pitch, "chip chip chip wheedoe iee iee iee iee iee", reminiscent of that of a New World warbler (Parulidae). Call a sharp "chip".
Habitat. Montane conifer and pine–oak (*Pinus–Quercus*) forests; some populations move to lower elevations in winter. In S Baja California (Mexico), *bairdi* occurs in semi-arid oak and pine–oak woodlands. At 1600–3500 m in USA and most of Mexico; 1200–1900 m in S Baja California; 2000–3500 m Guatemala and adjacent Mexico (Chiapas).
Food and Feeding. Feeds on insects and other arthropods, and seeds; during breeding season mostly insects, especially Lepidoptera, beetles (Coleoptera), ants (Formicidae) and flies (Diptera), and in winter mainly seeds. In pairs; small flocks outside breeding season. Forages principally on or near ground or low in vegetation, usually not far from cover. Runs or hops on the ground; uncovers seeds, insects and other foods by double-scratching (using both legs together) or by scratching with one leg. In autumn and winter may glean seeds from grasses. Occasionally flycatches.
Breeding. Nests found between mid-Apr and early Aug in S USA (Arizona) and in May and early Jun in SC Mexico (Morelos); up to three broods in a year. Following information almost strictly from N population of nominate race (in Arizona); little known about Mexican and Central American populations. Apparently monogamous; pairs form by mid-Apr in Arizona, pair formation by first-year individuals may occur in wintering flocks. Nest-building takes up to 9 days, begins several weeks after pair formation, nest made from dry grasses and mosses, lined with hair and finer grasses, placed on ground, generally under tuft of grass and typically on slope, rather than on level ground; rarely, nest placed off ground on branch of conifer. Clutch usually 3–4 eggs (1–5), pale blue or greyish-white with dark brownish or reddish spotting typically concentrated around wide end (sometimes relatively well spread over egg); incubation solely by female, period 11–15 days (usually 13 days); chicks fed by both parents, nestling period 10–13 days, at which age young can fly weakly and for short distance.
Movements. Mostly sedentary; in Arizona often moves to lower elevations in winter. In Chiricahua Mts (SE Arizona), descends in Aug and Sept and return upslope in Feb; exhibits site-fidelity to wintering and breeding areas. Curiously, if mild winter weather occurs, will venture up to higher-lying breeding sites, coming back down when bad weather returns.
Status and Conservation. Not globally threatened. Common or abundant in appropriate habitat in many parts of range. In N part of range, numbers seem to decline during times of drought.
Bibliography. Armani (1985), Beadle & Rising (2002), Bent & Austin (1968), Caraco *et al.* (1990), Griscom (1932), Hainsworth *et al.* (1998), Hellmayr (1938), Horvath & Sullivan (1988), Howell & Webb (1995), Kirkpatrick & Conway (2010), Kirkpatrick *et al.* (2009), Lamm & Luepke (1982), Leary & Sullivan (1991), Milá *et al.* (2007), Miller (1941), Miller *et al.* (1957), Pulliam *et al.* (1974), Pyle (1997), Ridgway (1901), Rising & Beadle (1996), Rowley (1962), Sullivan (1988a, 1988b, 1990, 1999), Sullivan & Roper (1996), Sullivan & Weathers (1992), Sullivan *et al.* (1989), Weathers & Sullivan (1989a, 1989b, 1991a, 1991b, 1993).

57. Dark-eyed Junco

Junco hyemalis

French: Junco ardoisé **German**: Winterammer **Spanish**: Junco Pizarroso
Other common names: Slate-colored Junco ("*hyemalis* group"); Oregon Junco ("*oreganus* group"); Grey-headed Junco ("*caniceps* group"); White-winged Junco (*aikeni*); Guadalupe Junco (*insularis*); Pink-sided Junco (*mearnsi*); Red-backed Junco (*dorsalis*)

Taxonomy. *Fringilla hyemalis* Linnaeus, 1758, South Carolina, USA.
Molecular data indicate close relationship between this genus and *Zonotrichia*. Nominate race has hybridized with *Zonotrichia albicollis*. Recent molecular-genetic studies suggest that genus spread quickly N from Central America in post-glacial period; although morphological divergence high, molecular divergence not so well marked; on the other hand, the farther S in Central America, the older is the lineage, and the more distinctly characterized it is molecularly. Taxonomy of present species complex; races molecularly very close to each other, and more closely allied to N races of *J. phaeonotus* than to S populations of latter; S races of present species very similar morphologically to *J. phaeonotus*, and unpublished molecular data suggest that Guadalupe race *insularis* may be better placed with that species. Races form six groups: "*hyemalis* group" (nominate, *carolinensis*, *cismontanus*), "*oreganus* group" (*oreganus*, *shufeldti*, *montanus*, *thurberi*, *pinosus*, *pontilis*, *townsendi*), "*caniceps* group" (*caniceps*, *dorsalis*, *mutabilis*), and three single-subspecies groups, i.e. "*aikeni* group", "*insularis* group" and "*mearnsi* group"; these sometimes treated as six separate species, but hybridization occurs among them and several races intergrade with others from different group (*cismontanus* often considered a hybrid between nominate and "*oreganus* group"). In the past, race *dorsalis* sometimes treated as a separate species. Proposed race *eumesus* (from Blue Mts of Washington) included within *shufeldti*. Availability of name *shufeldti* has been disputed, and replacement name *simillima* proposed. Sixteen subspecies currently recognized.
Subspecies and Distribution.
J. h. hyemalis (Linnaeus, 1758) – breeds Alaska and across Canada from C Yukon, NW & C Mackenzie and SW Nunavut E to N Quebec, Labrador and Newfoundland and S to NE British Columbia, C Alberta, C Saskatchewan, S Manitoba and NE USA (S to C Minnesota, SE Wisconsin, C Michigan, W & N Pennsylvania, SE New York, Connecticut and Massachusetts); non-breeding from S edge of breeding range S (mostly E of Rocky Mts) to NW Mexico (N Baja California, N Sonora and C Chihuahua) and Gulf Coast (S Texas E to NE Florida).
J. h. cismontanus Dwight, 1918 – breeds SC Yukon S to C interior of British Columbia and WC Alberta; non-breeding from S coastal British Columbia S to extreme NW Mexico (N Baja California) and SW USA (S to Arizona and New Mexico, E to Minnesota, Wisconsin, Nebraska, Kansas, Oklahoma and C Texas.
J. h. oreganus (J. K. Townsend, 1837) – breeds SE Alaska S to Calvert I, in CW British Columbia; non-breeding also S along coast to C (rarely S) California.
J. h. shufeldti Coale, 1887 – breeds on W slope of coastal ranges from SW British Columbia S in W USA to W Oregon (to c. 43° N); non-breeding S to S California, sparsely also to SE Idaho, Colorado, W Texas and N Mexico (Chihuahua).
J. h. montanus Ridgway, 1898 – breeds in C interior British Columbia and SW Alberta S in W USA to E Oregon, W Montana and C Idaho; non-breeding to S British Columbia, W Montana and South Dakota S to N Mexico (N Baja California, N Sonora and C Chihuahua) and S USA (to C Texas and E Kansas).
J. h. thurberi Anthony, 1890 – breeds S Oregon and California (S on coast to San Francisco, and in interior mountains to San Diego County); non-breeding also in adjacent lowlands E to Arizona and SW New Mexico and S to NW Mexico (Baja California and Sonora).
J. h. pinosus Loomis, 1893 – coastal ranges of C California (from San Francisco S to San Benito and S Monterey County).
J. h. pontilis Oberholser, 1919 – Sierra Juárez, in N Baja California (NW Mexico).
J. h. townsendi Anthony, 1889 – Sierra San Pedro Mártir, in N Baja California.
J. h. aikeni Ridgway, 1873 – breeds SE Montana, W South Dakota, NE Wyoming and NW Nebraska; non-breeding also S to SW Colorado, W Kansas, N New Mexico and W Oklahoma.
J. h. mearnsi Ridgway, 1897 – breeds extreme S Canada (SE Alberta and SW Saskatchewan) S in USA to E Idaho, C Montana and NE Wyoming; non-breeding from N Utah, NW Wyoming and W & C Nebraska S to N Mexico (N Sonora, C Chihuahua and Durango) and W Texas.
J. h. insularis Ridgway, 1876 – Guadalupe I, off NW Baja California (NW Mexico).
J. h. caniceps (Woodhouse, 1853) – breeds in mountains of S Idaho and S Wyoming S to C & E Nevada, S Utah, W & C Colorado and N New Mexico; non-breeding also E to W Nebraska, W Kansas and W Texas, S to N Mexico (Sonora, N Sinaloa, Chihuahua and N Durango).
J. h. dorsalis Henry, 1858 – breeds in mountains of New Mexico, extreme W Texas and N Arizona; non-breeding also slightly farther S.
J. h. mutabilis van Rossem, 1931 – mountains of S Nevada and adjacent SE California.
J. h. carolinensis Brewster, 1886 – breeds E USA in Appalachian Mts (from NW West Virginia and W Maryland S to N Georgia); winters in breeding area, and adjacent lower elevations.

Descriptive notes. 13–17 cm, 14·3–25·4 g ("*hyemalis* group", Pennsylvania); 14–15·4 cm, male average 18 g, female 17·8 g ("*oreganus* group", Oregon), male *townsendi* average 18·8 g; 14·9–16·8 cm, average 22 g (*aikeni*); 13·8–15·5 cm, 15·5–23·5 g (*mearnsi*); 13·6–14·4 cm (*insularis*); 13·9–16·3 cm, 18–23 g ("*caniceps* group"). A medium-sized sparrow with white outer tail feathers. Male nominate race has plumage slate-grey, except for white belly and undertail-coverts (grey continuing from breast down flanks to thigh feathers), outer two pairs of tail feathers and variable area near tip of adjacent pair white, wing feathers with indistinct paler edges and tips; iris red-brown to dark ruby-red; bill pinkish-white; legs flesh-coloured to deep purplish-brown, feet often duller and darker, sometimes markedly so. Female is somewhat paler than male, often washed with brown, edges of wing feathers (especially tertials) browner; occasionally has white tips on upperwing-coverts. Juvenile is like adult, but much more brownish. Races differ mainly in plumage coloration and pattern, also in size: *cismontanus* has hood darker, blacker, and back browner than nominate; *carolinensis* is a little larger and paler (more blue-grey) than nominate, also bill darker; in "*oreganus* group", *oreganus* is relatively small, male with blackish hood, reddish-brown upperparts, grey rump, pinkish-cinnamon flanks, *shufeldti* is somewhat paler and duller than *oreganus*, *montanus* is like previous but wing and tail shorter, *thurberi* also is similar but very slightly paler, *pinosus* resembles previous but a little paler, *townsendi* has pinkish area on flanks narrower, *pontilis* is intermediate between previous and *thurberi*; *aikeni* is largest race, relatively large-billed, paler grey than nominate, lores usually contrastingly dark, more white in tail (outer three pairs all white, two adjacent pairs usually with some white near tip), usually two conspicuous white wingbars, sexes similar, juvenile usually with white wingbars; *mearnsi* is large, has head and breast light grey, lores dark slate, back dull brown, flanks (sometimes also breast) pinkish cinnamon-brown, more white in tail (like previous race), and has paler grey hood than *insularis*, with duller upperparts and somewhat paler pinkish sides and flanks; *insularis* is like members of "*oreganus* group", but wing and tail shorter, bill proportionately longer, and plumage in general (especially on head) paler, on average less white in tail than most other races; in "*caniceps* group", *caniceps* is medium-sized, mostly pale grey (much paler than nominate), with dark lores and black area around eye, mantle dark rusty red, tail grey with white lateral rectrices, belly and vent white (little contrast with grey of breast and flanks), bill all yellow, *dorsalis* is very similar but with dark upper mandible, *mutabilis* is somewhat darker and with mantle duller rufous, flanks pinkish. Voice. Song, used commonly during breeding season and given throughout year, usually from tree perch, generally a simple trill on one pitch. Call a simple "tit tit tit", also a smacking "tack tack tack". Some geographical variation, e.g. *insularis* song less trilling and more varied, including some buzzing notes, also "*caniceps* group" said to have more varied song; further study needed.

Habitat. Breeds in variety of woodlands, especially open woodlands with conifers, and cut-over woodlands; common after burns. Sea-level to 2040 m in E, to 3775 m in Rocky Mts; race *townsendi* above 1800 m. In W of range, common in urban parklands and gardens; in Allegheny Mts (Appalachians) most common in brushy edge habitats at up to 900 m. Members of "*oreganus* group" breed in open coniferous forests, moist redwood (*Sequoia*), dry pine (*Pinus*) forests, aspens (*Populus*), compact low conifers at timber-line, also in live oak (*Quercus agrifolia*), oak–madroño (*Quercus–Arbutus*) associations, digger pines (*Pinus sabiniana*) and Coulter pines (*Pinus coulteri*), Monterey cypress (*Cupressus macrocarpa*), eucalypts (*Eucalyptus*), and on coast also in city parks and gardens. Race *aikeni* generally in pine forest, but can be found also in spruce (*Picea*) and aspen; "*caniceps* group" often in conifers, e.g. spruce, Douglas-fir (*Pseudotsuga*) and lodgepole pine (*Pinus contorta*), and fir (*Abies*), but also in variety of hardwoods, e.g. aspen, oak and mountain mahogany (*Cercocarpus*), and more likely than the others to be found in rather arid woodlands; *mearnsi* breeds most commonly at edge of pine woods, but occurs also in other edge habitats. Race *insularis* mostly limited to Monterey pine–island oak (*Pinus radiata–Quercus tomentella*) and Guadalupe cypress (*Cupressus guadalupensis*) groves at N end of Guadalupe I, at up to 1400 m, but can be found also in *Nicotiana* scrub at sea-level. In non-breeding season, occupies a variety of edge habitats and open woods with brushy understorey, and often visits feeders; in winter members of "*oreganus* group" mainly in pinyon–juniper (*Pinus–Juniperus*) woods, sage (*Artemisia*) and urban gardens.

Food and Feeding. In studies in W USA (California), diet for all months combined (except May) consisted of 24% animal items and 76% vegetable matter. Insects comprise most of animal food, but some spiders (Araneae) also taken; insects most commonly eaten are beetles (Coleoptera), adult and larval Lepidoptera, also ants and wasps (Hymenoptera) and flies (Diptera). Seeds, which comprise 62% of diet, include those of chickweed (*Stellaria*), pigweed (*Amaranthus*), alfilaria (*Erodium*), knotweed (*Polygonum*) and sorrel (*Rumex*); plant material 76% of diet of "*hyemalis* group" in Nov–Mar, 40% in Apr–May, 93% in Jun–Aug and 92% in Sept–Oct; for "*oreganus* group in California, percentage figures for same time periods were, respectively, 74%, 52%, 95% and 91%. Forages principally on or near ground or low in vegetation; also in trees, males on average higher up than females. In E of range in breeding season, finds most food in leaf litter. On migration and in winter feeds almost exclusively on ground, where it hops and occasionally runs. Outside breeding season usually in flocks, sometimes large ones; sometimes mixes with other seed-eating species.

Breeding. Apr–Aug on coast and from Jun in interior in British Columbia, May–Jul in Ontario, Apr–Aug in Virginia, and from as early as Jan on Guadalupe I (race *insularis*); May in Sierra San Pedro Mártir (*townsendi*); generally double-brooded in S parts of range. Monogamous; rarely polygynous (two of more than 200 colour-marked individuals of race *carolinensis*). Nest-site chosen by female, she also builds nest, taking 3–7 days, a coarse grass foundation, with cup composed of finer dry grasses, rootlets and moss, lining often includes softer grasses, hair and moss, placement variable, usually in cavity on slope, bank, under rock or roots, sometimes under bush or fallen tree or even beneath deck or elevated building; c. 10% of nests placed above ground in artificial structure, root mass or similar. Clutch 3–5 eggs, usually 4, (clutch size varies geographically, smaller in high-elevation populations), white to pale bluish with red-brown and purplish-grey specks and spots; incubation by female, period 12–13 days (rarely, 11 days); chicks fed by both sexes roughly at equivalent rates, nestling period 9–12 days. Nests in S of range commonly parasitized by Brown-headed Cowbird (*Molothrus ater*); in some California populations c. 30% of nests parasitized, and in Appalachians (race *carolinensis*) up to 40%.

Movements. Mostly migratory; males migrate earlier than females, and tend (in E) to winter farther N, but analysis of other climatic variables reveals that, both in W and in E, the best predictor of male skew in wintering sex ratio is greater severity of weather. Some populations (such as *carolinensis* and some S montane populations in W) are sedentary, short-distance migrants or altitudinal migrants; these include some *pontilis*, *townsendi* and *dorsalis*, lower-elevation and coastal breeding races such as *pinosus*, *shufeldti* and *thurberi*, and island race *insularis*. Generally, autumn migration begins mid-Aug in S Canada and N USA, but N breeders typically begin to move S from Sept into late Oct/Nov; arrival in wintering sites from early Oct, completed by start of Dec. Females (which move farther S on average than males) begin migration earlier; similarly, younger females (which winter farther N than adults) trail in their migration timing, and ringing analysis shows that females on second S-bound migration move farther S than they did in first autumn. In spring, N-bound movements from wintering areas noted by start of Mar, with peak mid-Mar to early Apr; males arrive before females, from a few days to a week earlier. Overall, migration in E much more clearly understood than variety of complex movements (both to N and to S, altitudinally, often through areas where some populations resident) in W. Specific examples of migration timing include the following: arrival in Alaska in late Apr or early May; in N boreal forests of British Columbia, autumn migration begins mid-Aug, most have left taiga plains by end Sept and N parts of the province by end Oct, arrival in spring in first week Apr and migration continues into mid-May; in Ontario, migration takes place Mar to early May and Sept to early Dec; in Virginia, spring migration Feb–Mar and autumn migration Sept–Nov; in N Mexico (Sonora), arrival by mid-Oct and departure by mid-May. Migration commonly takes place at night, and generally involve as single individuals, but often gathering in small foraging flocks during day. Occurs casually N to arctic coast of Alaska and in N Canada on Banks I, Baffin I and Southampton I, and S to E Mexico (Veracruz), Bahamas, Jamaica and Puerto Rico; nominate race recorded in Russian Far East in Chukotka and on Wrangel I, and race *oreganus* recorded Wrangel I. Vagrants recorded in Iceland, British Is (34 records), Norway, Denmark, Netherlands, Poland, Italy and Gibraltar.

Status and Conservation. Not globally threatened. Race *insularis* often treated as a separate species, of restricted range: present in Guadalupe Island EBA. Often common or very common in appropriate habitat throughout range. Forest-management practices and fires can affect numbers during breeding season, but this species is so abundant, and has such varied ecological preferences in different parts of its range, that no conservation measures (in terms of management) have been designed specifically to benefit it. Apparently does well after fires and logging, although in the short term this would destroy habitat locally. Can breed commonly in regenerating clear-cuts. Cowbird parasitism decreases the number of young fledged, but no evidence of adverse influence at population level; heavily parasitized Californian populations appear to sustain healthy numbers over time.

Genus *ZONOTRICHIA* Swainson, 1832

58. **Rufous-collared Sparrow**

Zonotrichia capensis

French: Bruant chingolo **German**: Morgenammer **Spanish**: Chingolo Común
Other common names: Central American Crowned Sparrow (Central American races); Andean Sparrow (Andean races)

Taxonomy. *Fringilla capensis* Statius Müller, 1776, Cape of Good Hope; error = Cayenne, French Guiana.
Genus probably close to *Junco*. Has been suggested that present species more closely related to *Melospiza* than to current congeners. Geographical variation both in size and in coloration, although size variation not so pronounced as in some other New World sparrows; excluding very pale *insularis* (S Caribbean), birds from farthest S parts of range (*australis*) are palest and those from highlands of Brazil (*macconnelli*) darkest; morphologically the most divergent is the large and very long-winged *australis*. Numerous races have been proposed, but many are poorly differentiated; *orestera* may be better treated as a synonym of *costaricensis*, and *mellea* perhaps better subsumed in *hypoleuca*; at present, *perezchinchillorum* (described from Cerro Marahuaca, in S Venezuela) and *bonnetiana* (Sierra Chiribiquete, in S Colombia) subsumed into *roraimae*, and *markli* (lowland NW Peru) into *huancabambae*. Comprehensive revision of subspecific taxonomy required. Twenty-five subspecies presently recognized.
Subspecies and Distribution.
Z. c. septentrionalis Griscom, 1930 – highlands of S Mexico (Chiapas) S to Honduras and El Salvador.
Z. c. costaricensis J. A. Allen, 1891 – mountains of El Salvador, Costa Rica and W Panama (E to Veraguas); Santa Marta Mts (N Colombia) and Andes from Venezuela (S from C Lara) S to Ecuador.
Z. c. antillarum (Riley, 1916) – Cordillera Central, in Dominican Republic.
Z. c. orestera Wetmore, 1951 – Cerro Campana (extreme SW Panamá Province), in C Panama.
Z. c. insularis (Ridgway, 1898) – Curaçao I and Aruba I, in Netherlands Antilles.
Z. c. venezuelae Chapman, 1939 – N & C Venezuela (coastal mountains from Yaracuy E to Miranda, and Anzoátegui E to Sucre; Quiribana de Caicara, in NW Bolívar).
Z. c. inaccessibilis Phelps, Sr & Phelps, Jr, 1955 – headwaters of R Yatúa, on Cerro de la Neblina (S Amazonas), in S Venezuela.
Z. c. roraimae (Chapman, 1929) – Sierra de la Macarena (Meta), in C Colombia; E & S Venezuela (NW Amazonas and tepuis and Gran Sabana of SE Bolívar) and adjacent W Guyana and N Brazil.
Z. c. macconnelli Sharpe, 1900 – summit of Mt Roraima, in SE Bolívar (SE Venezuela).
Z. c. capensis (Statius Müller, 1776) – lower R Oyapock, in NE French Guiana; presumably also adjacent NE Brazil (Amapá).
Z. c. huancabambae Chapman, 1940 – arid subtropics of N & C Peru (Piura, Cajamarca, Amazonas and San Martín S to Junín).
Z. c. illescasensis Koepcke, 1963 – Cerro Illescas (Piura), in NW Peru.
Z. c. peruviensis (Lesson, 1834) – arid coastal Peru from La Libertad S to Tacna, and inland on W slope of Andes.
Z. c. carabayae Chapman, 1940 – E slope of Andes from C Peru (Junín) S to Bolivia (La Paz and Cochabamba).
Z. c. pulacayensis (Ménégaux, 1908) – Pulacayo and Pampas de Pazña, in L Poopó region (Oruro department), in W Bolivia.
Z. c. tocantinsi Chapman, 1940 – lower Amazonia (along R Tocantins and probably along lower Amazon E from Monte Alegre), Brazil.
Z. c. matutina (M. H. C. Lichtenstein, 1823) – NE & C Brazil (from Maranhão S to N & C Mato Grosso and Bahia) and adjacent E Bolivia (Santa Cruz).
Z. c. subtorquata Swainson, 1837 – SC & SE Brazil (from S Mato Grosso and Espírito Santo) S to E Paraguay, NE Argentina (Misiones) and Uruguay.
Z. c. mellea (Wetmore, 1922) – C Paraguay (W side of R Paraguay) and N Argentina (Formosa).
Z. c. hypoleuca (Todd, 1915) – E & S Bolivia (E Cochambama, Santa Cruz, Chuquisaca, Tarija, possibly also C La Paz) and *llanos* of N Argentina (Salta and La Rioja S to San Luis, Córdoba and S Buenos Aires).
Z. c. antofagastae Chapman, 1940 – Tarapacá and Autofagasta, in N Chile.
Z. c. chilensis (Meyen, 1834) – C Chile (sea-level to *puna* zone) from Atacama S to Guaitecas Is, and W Argentina on E slopes of Andes (Mendoza and Neuquén, and Río Negro).
Z. c. sanborni Hellmayr, 1932 – High Andes of Coquimbo and Aconcagua (Chile) and San Juan (W Argentina).
Z. c. choraules (Wetmore & J. L. Peters, 1922) – lowlands and foothills of W Argentina in Mendoza, E Neuquén and Río Negro.
Z. c. australis (Latham, 1790) – breeds S Chile (S from Aysén) and S Argentina (S from S Neuquén and Río Negro); migrates N probably as far as N Bolivia.

Descriptive notes. 11·8–13·4 cm; 16·8–31 g. A medium-sized sparrow with often peaked-looking crown, and a medium-sized conical bill. Nominate race has grey head, including grey median crownstripe, with black lateral crownstripe, postocular stripe and lower edge of ear-coverts; nape and side of neck rufous (forming rufous collar), this colour often extending to side of breast, where bordered above by black patch; upperparts brown, mantle streaked blackish, upper back and scapulars; tail feathers brown with rufous-brown edging; upperwing brown, feathers edged rufous, median coverts tipped whitish and greater coverts tipped buffy to whitish (forming two wingbars); throat white, breast greyish-white, becoming whitish below, flanks to undertail-coverts buffy; iris reddish-brown; bill horn-coloured to greyish, with black culmen and tip; legs brownish-pink. Sexes similar in coloration. Juvenile has face pattern buff and brown (not grey and black) and somewhat streaky, lacks black breast patch and rufous collar, and is extensively streaked below. Races vary mainly in depth of coloration and in head pattern, also in size: *costaricensis* is well streaked above, rufous collar well defined, black breast-side patches bigger and more or less meeting on centre of breast; *septentrionalis* is similar to previous, but less streaked above, and rufous collar less well defined; *antillarum* is like last, but black breastband broader and more complete, rufous collar smaller, yellow at bend of wing; *orestera* is very like *costaricensis*, but on average darker; *insularis* is palest of all races, greyish above, less contrasting and less distinct head pattern than other tropical races, and restricted black on breast side; *venezuelae* is similar to *costaricensis*, but paler below, also slightly paler than nominate but with more extensive black on breast side; *macconnelli* is darkest race, crown essentially blackish with almost no grey median stripe; *inaccessibilis* is like previous, but darker rufous collar, darker grey on breast and darker on flanks, has noticeably rufous edgings on flight-feathers; *roraimae* also is like *macconnelli*, but smaller and paler, less black on crown, is darker and more heavily streaked above than nominate; *tocantinsi* is like nominate, but has less black on side of breast, browner flanks, brighter rufous neck collar; *matutina* resembles nominate, but paler, with more grey than black on crown, very little black on breast side; *subtorquata* is like nominate, but with yellow bend of wing; *hypoleuca* is paler than previous, has white bend of wing (like *matutina*, but smaller, and less rufous above); *mellea* is barely different from last; *huancabambae* is rather small, resembles *costaricensis*, but somewhat larger-billed and slightly paler below; *peruviensis* resembles last, but larger and more heavily streaked, whiter below, and relatively short-tailed; *illescasensis* is similar to preceding two races; *carabayae* has bright rufous upperparts, making rufous collar less contrasting, underparts greyish; *antofagastae* is rufous above, like last, with strong buff wash on flanks to undertail-coverts; *pulacayensis* is slightly larger, a little less bright and more heavily streaked above than previous, and less buff below; *chilensis* is rather pale, has greyish-looking head very narrowly dark-striped; *sanborni* is like previous, but larger, with paler upperparts, creamy-washed underparts; *choraules* also resembles *chilensis*, but paler, with narrower crownstripes, less black on breast side; *australis* is large and very long-winged, has head almost uniformly grey with only traces of black. Voice. Song simple, a series of whistles and a terminal trill. Can be sweet and plaintive, e.g. "see-seeur tee-te-e-e-e, seeeeur tse-e-e-e-e", in some places with trill reduced to a few notes. In S temperate populations males apparently sing only one stereotyped song, but in Ecuador and Costa Rica males may have repertoire of various (up to seven) songs; populations lacking trills tend to be more tropical and based at forest edge; some montane-grassland populations give two terminal trills in songs. This is one of main species studied to support Acoustic Adaptation Hypothesis (which suggests that song variation may be due to variation in acoustic landscape of different habitats); in grasslands gives higher-pitched trills, and in forest edge more prominent are slowly delivered and lower-pitched whistles. Call a sharp "chip" or "chink", varying geographically.
Habitat. Open spaces, from sea-level to high elevation, c. 4600 m. Often on roadsides, in parks, and near dwellings; also in cleared areas, in blackberry (*Rubus*) and wild rose (*Rosa*) thickets, and in old clearings with bracken (*Pteridium*) and pines (*Pinus*). Race *inaccessibilis* to 1900 m, *roraimae* at 1100–2200 m, *macconnelli* to 4300 m, *antofagastae* sea-level to 2500 m, *pulacayensis* at 4200 m, *peruviensis* sea-level to 4300 m in *puna* zone.
Food and Feeding. Little information on diet; probably feeds on seeds, fruit and arthropods, depending on season and availability. Forages principally on or near ground and low in vegetation. Immatures and non-breeding individuals gather in small flocks.
Breeding. Breeds at all times of year throughout range, but with defined seasons locally, and nesting cycles may be defined by climatic cycles: in El Salvador breeding by May and in Costa Rica breeds in Feb–Apr and Jun–Aug; in Argentina seemingly breeds twice in a year. Monogamous. Nest a compact cup of grasses and plant fibres, lined with finer material, including hair, placed on ground or up to 1 m above it in Costa Rica; in El Salvador nest commonly placed in epiphytes on isolated tree in cleared area. Clutch 2–3 eggs in El Salvador and Costa Rica, 4–5 in Argentina, pale greenish-blue with dense brown spots and blotches; no information on incubation and nestling periods.
Movements. Mostly resident. Patagonian race *australis* migratory, moving N in May after breeding and returning S in Sept; exact location of non-breeding quarters not known. Otherwise, mountain populations in C Chile and Argentine Andes experience extreme cold and snow during winter in regions where they breed; presumably descend to lower elevations, but not yet studied. Montane populations farther N remain in breeding areas all year, as conditions during winter months not nearly so harsh.
Status and Conservation. Not globally threatened. Often common or abundant in appropriate habitat. No indications of any decrease in numbers, and no obvious threats.

59. **Harris's Sparrow**

Zonotrichia querula

French: Bruant à face noire **German**: Harrisammer **Spanish**: Chingolo de Harris

Taxonomy. *Fringilla querula* Nuttall, 1840, few miles west of Independence, Missouri, USA.
Genus probably close to *Junco*. Monotypic.
Distribution. Breeds in Canada from N Mackenzie (possibly from Yukon) E to C Nunavut, S to NE Saskatchewan, N Manitoba and NW Ontario. Winters in C & S USA primarily from SW South Dakota, N Nebraska and C Iowa S, E of foothills and W of R Mississippi, to SC & C Texas.
Descriptive notes. 16–19 cm; 28·4–48·8 g. A large sparrow with long tail. Has crown, eyestripe, face, chin and throat black, eyestripe brownish-buff in fresh (autumn) plumage; above and around eyestripe, including ear-coverts and side of neck, grey, with black patch or spot at back of ear-coverts; nape brownish; back and scapulars brown, broadly streaked brownish-black, rump brownish; upperwing brownish, tips of median and greater upperwing-coverts edged with white or buffy

On following pages: 60. White-crowned Sparrow (*Zonotrichia leucophrys*); 61. White-throated Sparrow (*Zonotrichia albicollis*); 62. Golden-crowned Sparrow (*Zonotrichia atricapilla*); 63. Song Sparrow (*Melospiza melodia*); 64. Lincoln's Sparrow (*Melospiza lincolnii*); 65. Swamp Sparrow (*Melospiza georgiana*); 66. Savannah Sparrow (*Passerculus sandwichensis*); 67. Belding's Sparrow (*Passerculus guttatus*); 68. Large-billed Sparrow (*Passerculus rostratus*); 69. San Benito Sparrow (*Passerculus sanctorum*).

white (forming two wingbars); tail brown, slightly notched; iris deep brown; bill pink; legs fleshy-pink to fleshy-brown. Sexes similar, male slightly larger and perhaps on average brighter than female. Juvenile has forehead and crown streaked black, side of head creamy buff with some black streaking, nape and upperparts dull chestnut or mottled with dark, back streaked and mottled, rump greyer and mottled with black; upperwing blackish, feathers narrowly edged buff, median and greater upperwing-coverts narrowly tipped white (two wingbars); chin and throat white, spotted with black; centre of breast with conspicuous black spot, chin and flanks buffy and heavily streaked, belly whitish. VOICE. Song consists of one to several clear whistled notes in same minor key, often following other notes that may be in different key, sometimes ending with slow trill. Call a loud "chip" or "wink".

Habitat. Found at forest–tundra interface in islands of white spruce (*Picea glauca*), black spruce (*Picea mariana*) and tamarack larch (*Larix laricina*), with scattered dwarf willow (*Salix*), birch (*Betula*), alder (*Alnus*), Labrador tea (*Rhododendron*), and lichens. In non-breeding season in various shrubby edge situations, and commonly visits suburban backyards and bird-feeding stations. Sea-level to low elevations.

Food and Feeding. Invertebrates, also spruce needles; in winter eats seeds and fruits. Forages principally on or close to ground; in breeding season also gleans and chases arthropods, and makes aerial sallies to catch insects.

Breeding. Season mid-Jun to mid-Jul, nest-building beginning when snow-melt has occurred (typically, first half Jun); single-brooded. Monogamous. On arrival on breeding grounds males form territories, and pair formation follows. Nest built by female, requiring 2·5 days, constructed from sedges, grasses, moss and lichens, lined with softer grasses and sedges, placed on ground, usually beneath small shrub (alder, spruce, Labrador tea) and typically close to stand of conifers. Clutch normally 4 eggs, clutch size on average slightly larger in N part of range, eggs variable, typically pale green with brownish spots; incubation by female, period 12–15 days, normally 13 days (more only in cold-weather years); chicks fed by both parents, nestling period 8·5–10 days, commonly 9 days.

Movements. Migratory; entire population migrates through a relatively narrow corridor between breeding and wintering areas, largely bordered by E Saskatchewan and Manitoba, the Dakotas and W Minnesota. Begins to leave wintering sites late Feb and early Mar, but peak movements N of wintering areas not noted until late Apr and early May; arrival on breeding grounds at sites as distant as in Northwest Territories and in Manitoba (Churchill) occur typically in last week of May, but cold spring weather can delay arrival, and males and females arrive together. First S-bound movements from breeding sites late Aug/early Sept, peak movements in S Canada and N USA in Oct, and arrival in wintering areas not until mid-Nov to early Dec. Autumn migration appears to be slower than that in spring; one ringed individual from Saskatchewan was found in C USA (Iowa) 21 days later, having travelled an average of 61 km per day. Despite narrow migratory and wintering range through centre of North American continent, occurs as a vagrant on both coasts; also casually in N Alaska, and accidental in N Canada on Banks I (Northwest Territories) and Jenny Lind I (Nunavut), and in SE USA S to Florida.

Status and Conservation. Not globally threatened. Often common or very common in appropriate habitat. Relatively little known. Breeds in remote and isolated places where there is little human interference, and winters in old fields and woodland edge. Winter Christmas Bird Count data indicate a general decline in numbers since 1970s, but confirmation of this trend, and study of causes, remain to be made.

Bibliography. Anon. 60. White-crowned Sparrow

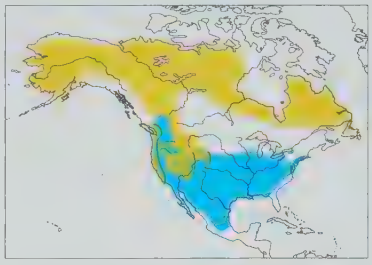
Zonotrichia leucophrys

French: Bruant à couronne blanche **German**: Dachsammer **Spanish**: Chingolo Coroniblanco
Other common names: California White-crowned Sparrow (*nuttalli*); Pacific White-crowned Sparrow (*pugetensis*)

Taxonomy. *Emberiza leucophrys* J. R. Forster, 1772, Severn River, west shore of Hudson Bay, Canada.

Genus probably close to *Junco*. Present species perhaps most closely related to *Z. atricapilla*, with which it hybridizes; hybrids with *Z. albicollis* and *Melospiza melodia* also recorded. Coastal races *pugetensis* and *nuttalli* differ from others morphologically, vocally, in breeding habitat, and in migration distance; biologically they are dissimilar, and it has been suggested that they would be better treated as two separate species. In Canada, race *gambelii* intergrades with *oriantha* in SE British Columbia and with nominate in N Manitoba. Proposed race *aphaea* (described from Idaho, presumably on migration) included within nominate. Five subspecies currently recognized.

Subspecies and Distribution.



Z. l. gambelii (Nuttall, 1840) – breeds Alaska and W Canada (E to Nunavut and N Manitoba, S to S British Columbia, SW Alberta and N Saskatchewan; non-breeding quarters in S British Columbia and W USA (E to NE Kansas, S to California) and Mexico (S to Nayarit, Aguascalientes and San Luis Potosí).

Z. l. leucophrys (J. R. Forster, 1772) – breeds in C & E Canada from N Manitoba and N Ontario E through N & NC Quebec to N Labrador and N Newfoundland; winters in S & SE USA (S from Kansas, Missouri, Kentucky and North Carolina) and N Mexico (S to Sonora).

Z. l. pugetensis Grinnell, 1928 – breeds extreme SW Canada (SW British Columbia) S along US coast to NW California; non-breeding S to SW California.

Z. l. nuttalli Ridgway, 1899 – coastal & C California (from Mendocino County S to Santa Barbara County).

Z. l. oriantha Oberholser, 1932 – breeds in mountains of SW Canada (SE British Columbia, S Alberta and SW Saskatchewan) and W USA (N Idaho S through SC Oregon to C & E California and SC Nevada, E to Wyoming, Utah, Colorado and CE Arizona); non-breeding SW USA (S California and S Arizona E to C Texas) and Mexico (S to S Baja California, Jalisco, Michoacán, Querétaro, San Luis Potosí and Nuevo León).

Descriptive notes. 14·0–17·0 cm; 21·0–38·5 g. A fairly large, long-tailed sparrow. Nominate race has broad white median crownstripe extending from back of head nearly to bill, black lateral crownstripes, narrow black eyestripe; side of face grey; nape greyish, upperparts boldly streaked brownish (feather centres) and grey; tail brown; median and greater upperwing-coverts with broad rufous edges and whitish tips (forming two wingbars); throat and underparts greyish, buff wash on flanks, undertail-coverts buff; iris dark brown; bill reddish-pink to yellow; legs fleshy-orange to pinkish-brown, often duller on feet. Sexes similar. Juvenile is like adult, but with head markings rusty brown where adult black and buffy where adult white. Races fairly well marked: *gambelii* is relatively large, with small bill, white supraloral area, bill pinkish with dark tip; *pugetensis* is shorter-winged than previous and nominate, has whitish supraloral area, browner (less greyish) above and below, bill yellowish or yellowish-orange with dark culmen and tip; *nuttalli* is similar in coloration to previous, but even shorter-winged, less slim, with larger bill, also often retains brown in crown into first summer (mature slightly later); *oriantha* is very like nominate, but marginally smaller, perhaps a shade paler above, bill perhaps very slightly darker pink. VOICE. Song variable, with many regional dialects, but distinctive, characteristically consists of 2 (1–4) clearly whistled notes, the second slightly lower than the first, followed by 3 descending buzzy or husky notes, "dear-dear buzz buzz buzz"; along Pacific coast usually starts with a long, clear whistle that is higher-pitched than rest of song. Call a hard "pink" or "tsit", somewhat flatter in tone on Pacific coast than elsewhere.

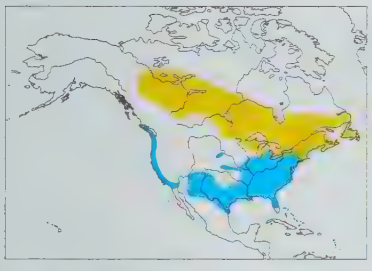
Habitat. In N parts of range breeds at tree-line in dwarf spruce–birch (*Picea–Betula*) and tamarack (*Larix laricina*) woods; in Rocky Mts in alpine meadows; on W coast found in coastal fog zone, usually in coastal scrub or edge habitats, sometimes in urban areas. In non-breeding season, N migrants found in brush and woodland edge; in Midwest often in hedgerows and grassy edges of woodland. Where coastal and interior races winter together, such as in C California, *gambelii* tends to occupy more open and arid habitats, while *pugetensis* prefers moister and more shrubby and closed habitats. Sea-level to 2500 m.

Food and Feeding. Diet during breeding season primarily arthropods, including larval Lepidoptera, beetles (Coleoptera) and bugs (Hemiptera). In winter eats small seeds (e.g. *Amaranthus*), buds and fruits, also arthropods when available. Forages principally on or near ground or low in vegetation. In pairs and small groups, often mixed with *Z. albicollis* and *Z. atricapilla* and with *Junco hyemalis*; on migration, often in moderately large flocks.

Breeding. Season varies geographically, breeds mid-Jun through Jul in C Canada (Manitoba and Ontario), and in USA begins late Apr to early May in Oregon, from late May through mid-Jun in mountains of Arizona and early Mar through early Apr in coastal California; generally single-brooded in N, multi-brooded on Pacific coast. Monogamous, occasionally polygynous (*nuttalli*). Nest built by female, taking 3–8 days, a cup of dry grasses, sticks, dead leaves or moss, lining includes finer grasses and hair, placement variable, in coastal areas often in low bush such as in coastal chaparral or scrub, farther N and in highlands tends to be on ground and concealed by overhanging branches of small tree or shrub such as spruce, tamarack, fir (*Abies*), crowberry (*Empetrum*) or Labrador tea (*Rhododendron*). Clutch 3–7 eggs, clutch size larger in N and smaller in S (nominate and *gambelii* typically 5 eggs, *oriantha* and *pugetensis* 4, *nuttalli* 3), eggs pale greenish to bluish and marked with brownish to reddish spots; incubation by female, period 11–13 days (normally 12 days); chicks fed by both parents, nestling period 8·5–10 days. Brood parasitism by Brown-headed Cowbird (*Molothrus ater*) most frequent in S populations of race *oriantha*, also for *nuttalli* in California (where parasitism rates can be quite high), but not recorded in N (e.g. *gambelii*).

Movements. N and montane populations entirely migratory; S coastal *nuttalli* sedentary, while more N *pugetensis* is migratory. In C California ringing data show that individuals, having chosen wintering area during first winter of life, return each year to same site. Overall, migration on broad front, although in W spring migration restricted to lower-elevation valleys (as highlands still under snow), whereas autumn passage through highland meadows (quite productive at this season) likely. S-bound migration may begin as early as early Aug in extreme N, reaching much of S Canada and N USA from middle to late Sept, and in S part of wintering areas arrival begins in early Oct and largely finished by mid-Nov; in C California arrival of wintering populations occurs by early Sept, and is broad scale by mid-Sept; on average, arrival of *pugetensis* in coastal C California slightly earlier than that of N race *gambelii*, and in spring *gambelii* may remain in wintering areas slightly later than *pugetensis*. Average stopover time for 382 migrating *gambelii* in autumn in California was 3·6 days, and mass gain was 0·4 g/day for 4–5 days, but c. 33% of individuals failed to put on weight. In spring, migration is progress throughout much of USA by early to late Mar, with peak in mid-Apr towards Canadian border and further pulses to early May; males reach breeding grounds on average a few days before females, but much overlap, and experienced breeders arrive before inexperienced ones. Comparative studies of survival of wintering *pugetensis* (shorter-distance migrant) and *gambelii* (longer-distance migrant) in San Jose (California) reveal that migration distance appears not to have negative effect on survival rates. Race *gambelii* is casual in Pribilof Is and Alaska and accidental in Japan; nominate race casual S to Florida, C Mexico (Aguascalientes), Cuba and Jamaica. Vagrant to Greenland, Iceland, Azores, Britain, France and Netherlands.

Status and Conservation. Not globally threatened. Often common or very common in appropriate habitat. Logging often benefits this species, as it thrives in young second growth on Pacific coast. Most of breeding range in N lies in areas with low human population densities, and in habitats little used by people.



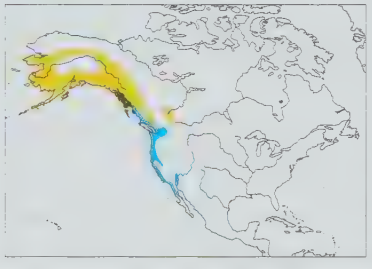
Bibliography. Anon. (1998), Baker (1975), Baker & Mewaldt (1979), Baker *et al.* (1981), Banks (1963), Baptista (1976), Beadle & Rising (2002), Caraco (1983), Chilton (2003), Chilton & Lein (1996a, 1996b), Chilton *et al.* (1995), Clement (1968), Cortopassi & Mewaldt (1965), Coverdill *et al.* (2008), Cramp & Perrins (1994), Derryberry (2009), Dunning (2008), Farner *et al.* (1980), Fugle *et al.* (1984), Glutz von Blotzheim & Bauer (1997), Hafner & Petersen (1985), Hahn *et al.* (2004), Harwood (2009), Hellmayr (1938), Hough *et al.* (2000), Howell & Webb (1995), Kern (1979), King & Mewaldt (1982), King *et al.* (1963), Lein & Corbin (1990), Lewington *et al.* (1991), Lewis *et al.* (1968), McCarthy (2006), Mead & Morton (1985), Mewaldt & King (1977), Miller *et al.* (1957), Morton (1967a, 1967b, 1992, 1997), Morton & Pereyra (1987), Morton & Welton (1973), Morton, Horstmann & Osborn (1972), Morton, Orejuela & Budd (1972), Nelson & Poesel (2009), Nelson & Soha (2004), Norment (1992, 2003), Norment & Fuller (1997), Orejuela & Morton (1975), Patterson & Petrinovich (1978), Peck & James (1987), Petrinovich (1985, 1988), Petrinovich & Patterson (1978), Petrinovich & Peeke (1973), Petrinovich, Patterson & Peeke (1976), Plamondon, Goller & Rose (2008), Plamondon, Rose & Goller (2010), Pleszczynska (1980), Pyle (1997), Ramenofsky *et al.* (2008), Rattenborg *et al.* (2004), Ridgway (1901), Rising & Beadle (1996), Sandercock & Jaramillo (2002), Simons & Alcock (1971), Slabbekoorn *et al.* (2003), Soha & Marler (2001), Trainer (1983), Urban (1959), Valone & Wheelbarger (1998), Webb & King (1983), Weckstein *et al.* (2001), Wheeler & Porter (2009), Zink, Dittmann & Rootes (1991).

61. White-throated Sparrow

Zonotrichia albicollis

French: Bruant à gorge blanche **German**: Weißkehlammer **Spanish**: Chingolo Gorjiblanco

Taxonomy. *Fringilla albicollis* J. F. Gmelin, 1789, Pensilvania = Philadelphia, Pennsylvania, USA.
Genus probably close to *Junco*. Hybrids between present species and *Z. atricapilla*, *Z. leucophrys* and nominate race of *Junco hyemalis* reported. Monotypic.
Distribution. Breeds in Canada (mainly E of Rocky Mts) from SE Yukon, WC & S Mackenzie, N & C Saskatchewan and N Manitoba E to Newfoundland, S to SC Alberta, S Saskatchewan, S Ontario, Vermont and Nova Scotia, and in NE USA S to NC North Dakota, N & E Minnesota, C Wisconsin, C Michigan, New York, New Hampshire, Massachusetts and N Pennsylvania. In non-breeding season found in SE Canada (S Maritimes, SE Quebec, rarely S Ontario), in USA from E South Dakota, S Wisconsin and S Michigan S to SC Florida and Gulf Coast, and from S Arizona E to S Texas, and in N Mexico (S to N Tamaulipas, Nuevo León, rarely to Sonora); also uncommonly along Pacific coast from extreme SW Canada (S British Columbia) S to extreme NW Mexico (N Baja California).



Descriptive notes. 15–17 cm; 19–35·4 g. A fairly large, long-tailed sparrow, polymorphic in head colour (a few birds intermediate). Has median crownstripe and broad supercilium either both white ("white-stripe morph") or both pale brownish-tan ("tan-stripe morph"), and always yellow from above eye to bill; lateral crownstripe and eyestripe dark chocolate-brown to black (generally darker in "white-morph" birds), ear-coverts and lores grey; mantle and scapulars brown or rusty brown, streaked dark brown or black, feathers edged beige, rump grey-brown with faint streaks; tail brown, slightly notched; upperwing brown, median and greater upperwing-coverts with brighter edges and tipped whitish (forming two narrow wingbars); throat white or dull white, sharply contrasting with greyish breast, which may be faintly streaked, flanks light brown and faintly streaked, belly dull white and unmarked; iris brown to deep reddish-brown; upper mandible dark horn-coloured, lower mandible lighter; legs flesh-coloured to pinkish-brown. Sexes similar in coloration, male slightly larger than female. Juvenile has median crownstripe indistinct, yellow in supercilium reduced or absent, forehead, crown and nape chestnut-brown, streaked black, chin and throat whitish, flaked with dusky, dark moustachial stripe, breast and flanks heavily streaked dark brown, belly and undertail-coverts white. Voice. Song a clear, loud whistle characteristically starting with lower note, this followed by 3 or 4 higher, wavering notes, or less frequently first note higher than others; song almost always has a change in pitch. Call a distinctive "tseet"; also quiet "tip" notes, and louder "pink" alarm call.
Habitat. Breeds in open coniferous and mixed forests, often in second growth following logging or fire, or along roadsides. On migration and in winter usually found in thick cover at woodland edge and in woodland clearings; visits gardens. To 3500 m.
Food and Feeding. In summer a variety of insects, including dragonflies and damselflies (Odonata), Hymenoptera, heteropteran bugs, and larval beetles (Coleoptera) flies (Diptera) and Lepidoptera, as well as spiders (Araneae), millipedes (Diplopoda), centipedes (Chilopoda) and snails (Gastropoda). Young fed with arthropods. In winter feeds principally on small seeds, e.g. ragweed (*Ambrosia*) and smartweed (*Polygonum*), and fruits (of *Viburnum*, *Sorbus*, *Rosa*), also arthropods when available. In early spring eats oak (*Quercus*) buds, and flowers of maple (*Acer*), beech (*Fagus*) and apple (*Malus*). Forages mainly on ground in small openings in dense thickets, often in leaf litter. Uses both feet together to scratch at soil and litter. In non-breeding season visits feeders. Singly and in pairs; outside breeding season often in large flocks, commonly with *Z. leucophrys* and *Junco hyemalis*.
Breeding. Breeds from late May to early Aug; sometimes double-brooded. Socially monogamous; rarely polygamous. Exceptionally unusual in having two colour morphs which correlate with slightly different behaviour: individuals mate in disassortative fashion, always choosing a partner of opposite morph, and in general white-stripe males more aggressive, territorial and more likely to mate outside pair-bond, and tan-stripe birds of either sex provide more parental care than do white-stripe ones; pair formation of tan-stripe males with white-stripe females begins earlier than that of white-stripe males with tan-stripe females, and nest-building by latter starts very soon after pairing, whereas pairs with tan-stripe male and white-stripe female start up to two weeks after pair formation. Nest built by female, a sturdy cup constructed from dry grasses, twigs, bark and moss, softer lining of finer grass, rootlets, pine (*Pinus*) needles and deer hair, usually placed on ground and concealed by vegetation, often under blueberry bush (*Vaccinium*), sometimes off ground in small tree or bush e.g. sweet gale (*Myrica gale*). Clutch 1–7 eggs, most commonly 4 or 5, clutch size on average larger farther N, eggs pale greenish or bluish with dark purplish or reddish-brown streaks, spots and scrawls; incubation by female, period 11–14 days, most frequently 12 days; chicks fed by both sexes, female doing on average more provisioning, but tan-stripe morph of either sex provisions more than does white-stripe morph of corresponding sex, thus white-stripe males feed young at lowest rates, while tan-stripe females feed at highest rates (as tan-stripe morph always pairs with white-stripe morph, overall provisioning rates of the two combinations are roughly equal); nestling period 7–12 days, most commonly 8–9 days. Brood parasitism by Brown-headed Cowbird (*Molothrus ater*) relatively uncommon, and in some populations unknown, owing to generally N breeding distribution.
Movements. Short-distance to medium-distance nocturnal migrant. Females winter farther S on average than males, and young females winter S of adult females. Migration generally on broad front, and mainly N–S; NW populations appear to have greater W–E component in migrations, moving towards SE wintering areas (rather than heading directly S). Breeding origin of sparse wintering population on Pacific coast not known, possibly W of Continental Divide. Wintering areas entirely vacated by late Apr to mid-May, although bulk of migrants leave well before that. Spring migration occurs from mid-Mar to late May; arrival in S breeding areas as early as late Mar, though more typically early to middle Apr, and reaches breeding areas farther N or W (N British Columbia, Newfoundland, Yukon) in first half May, sometimes early Jun; in Great Lakes region peak migration in last week Apr and first week May. During N-bound migration males travel 1–2 weeks earlier than females, and arrive earlier at breeding grounds; particularly with females, white-stripe morph moves N earlier than tan-stripe morph. Stable-isotope research indicates that time of arrival of spring migrants in Delta (Manitoba) is influenced by wintering latitude (not breeding latitude), body size and minimum temperatures during Apr. During S-bound migration adults and juveniles migrate at same time through Long Point (Ontario), but adults arrive on wintering grounds earlier, suggesting faster or more efficient migration by older birds; on average, S-bound migration slower and stopovers longer than during spring. In NW of breeding range (Yukon and C Alberta) S-bound passage begins late Aug into Sept, with peak in late Sept; peaks farther S and E, e.g. in S Ontario and Nova Scotia, during mid-Sept through late Oct; in main wintering range, arrivals span period from early Oct into Dec, with mid-Oct to mid-Nov as peak times of arrival. Casual or vagrant to Alaska, NC Canada (Kugluktuk, Baffin I and Coats I, in Nunavut), Iceland, British Is, Continental Europe (Fennoscandia, Netherlands, Germany, France, Gibraltar), and Puerto Rico.
Status and Conservation. Not globally threatened. Common to very common in appropriate habitat in many parts of range. Benefits from logging and fires. Has bred in N Germany (presumed to be escaped birds).

(1998), Beadie & Rising (2002), Christiansson & Gerell (1966), Denny (2005), Falls (1988), Falls & Kopachena (1995), Glutz von Blotzheim & Bauer (1997), Good & Adkins (1927), Hellmayr (1938), Hock (1973), Houtman & Falls (1994), Howell & Webb (1995), Hurly, Ratcliffe, Weary & Weisman (1992), Hurly, Ratcliffe & Weisman (1990), Hurly, Weisman *et al.* (1991), Jenkins & Cristol (2002), Kanerva (1967), Knapton & Falls (1983), Kontogiannis (1967), Kopachena & Falls (1993a, 1993b, 1993c), Lewington *et al.* (1991), Lowther & Falls (1968), Mazerolle & Hobson (2007), McCarthy (2006), Michopoulos *et al.* (2007), Mikkola & Rautatiek (1969), Miller, A.H. *et al.* (1957), Miller, L.J. & Weise (1978), Muheim *et al.* (2009), Pauly & Ferrell (1984), Peck & James (1987), Piper (1990a, 1990b), Piper & Wiley (1990a, 1990b), Pleszczynska (1980), Pyle (1997), Ridgway (1901), Riede & Suthers (2009), Rising & Beadle (1996), Russell & Monson (1998), Ruthke (1973), Stoffels & van der Weijden (1978), Thomas *et al.* (2008), Thorneycroft (1966), Vardy (1971), Wasserman (1977, 1986), Weeden & Weeden (1973), Whillans & Falls (1990), Zink, Dittmann & Rootes (1991).

62. Golden-crowned Sparrow

Zonotrichia atricapilla

French: Bruant à couronne dorée **German**: Kronenammer **Spanish**: Chingolo Coronidorado

Taxonomy. *Emberiza atricapilla* J. F. Gmelin, 1789, "in Sinu Natka, et insulis Sandwich" = Prince William Sound, Alaska, USA.
Genus probably close to *Junco*. Present species perhaps most closely related to *Z. leucophrys*, with which it sometimes hybridizes; hybridizes less frequently with *Z. albicollis*. Monotypic.
Distribution. Breeds in Aleutian Is (E from Unimak I and Shumagin Is) and W & NC Alaska, W Canada (C Yukon and probably SW Northwest Territories S to S British Columbia and SW Alberta) and adjacent USA (extreme NW Washington). Non-breeding from S Alaska and S British Columbia S to SW USA (S to W California and E Nevada) and NW Mexico (N & C Baja California, rarely S to Sonora).

Descriptive notes. 15–18 cm; 21·2–36·5 g. A fairly large, long-tailed sparrow. In breeding plumage, crown is blackish-brown, becoming brownish toward nape, with broad yellow or yellowish median crownstripe; lores yellow or grey, ear-coverts grey, sometimes with faint streaking; upperparts greyish olive-brown, mantle, back and scapulars broadly streaked with brownish-black, suffused with rusty brown, rump and uppertail-coverts greyish-brown; tail brown, slightly notched; median and greater upperwing-coverts edged rufous and with white tips (forming two thin wingbars); throat and underparts grey, becoming paler on belly, and buffy on flanks; iris deep brown; upper mandible mostly dusky, lower mandible flesh-coloured; legs pale brownish. In non-breeding plumage loses strong head pattern, but amount of black and golden colour retained varies individually, some largely brown on crown with dull golden centrally, others strongly black on much of crown and with brown restricted to rear portion and strong golden stripe down mid-crown; once non-breeding head pattern develops in second winter, that pattern maintained in consecutive winters. Sexes similar in coloration, male slightly larger than female. Juvenile and first-winter are like adult, but lateral crownstripes brownish, and crown brownish (sometimes tinged with yellow) and faintly brown-streaked. Voice. Song characteristically consists of 3 plaintive, clearly whistled descending notes in minor key, typically transliterated as "three blind mice" or "oh dear me". Call a loud "chink" or "chip"; flight call a high "seeep".
Habitat. Breeds in forest–tundra ecotone and shrubby tundra with scattered birch (*Betula*) and dwarf conifers (*Picea*, *Abies*), alders (*Alnus*), cottongrass (*Eriophorum*), sedges (*Carex*), Labrador tea (*Rhododendron*), blueberry (*Vaccinium*) and crowberry (*Empetrum*). In winter in brush, field edges, chaparral and gardens. Sea-level to 2700 m.
Food and Feeding. Little information on diet. Outside breeding season principally vegetable matter (seeds and fruits), and takes small insects and spiders (Araneae) when available; summer diet not well known, but thought to feed small insects such as Hymenoptera, Lepidoptera, beetles (Coleoptera), flies (Diptera) and other animal items to young. Also eats young cabbages, beets and peas. Forages principally on or near ground or low in vegetation. Scratches soil and leaf litter in search of food items; gleans items from vegetation.
Breeding. Season Jun–Jul; single brooded, rarely second broods attempted. Monogamous. Pair formation occurs within two weeks of arrival on breeding grounds. Nest constructed by female, a thick cup of grasses, twigs, ferns and moss, lining of fine grasses and sometimes ptarmigan (*Lagopus*) feathers, usually placed on ground, sometimes less than 1 m from ground in small stunted conifer; nest-site often in or near shrub thicket, sometimes near stream. Clutch typically 4 eggs, pale blue to pale greenish with brown, reddish or purplish spotting; incubation by female alone, period 11–12 days; chicks fed by both parents, nestling period at least 10 days.
Movements. Migratory. Passage largely along coastal slope, interior breeding populations likely using river valleys (highland areas still covered in snow during N movement). During first winter, individuals fix on a wintering area and return to it in subsequent winters. Wintering areas in USA extend rarely E to Colorado, Kansas and W Texas, and S in Mexico to Sonora. Migration N from California wintering areas begins in early Mar, peak in late Mar and early Apr, some remaining into late Apr or rarely early May; in Oregon main migration period mid-Apr to mid-May; reaches Alaskan breeding grounds from middle to late Apr into late May, males and females arriving at similar times. Begins to move out of breeding grounds from mid-Aug, and first S-bound migrants detected in coastal British Columbia, Washington and Oregon in late Aug to early Sept; arrival in C California usually by mid-Sept, although bulk of migrants occur in late Sept to mid-Oct. Vagrants recorded in Canada E to Nova Scotia and in USA to Massachusetts and Florida; W of normal range, accidental in Russian Far East (Wrangel I, Chukotka, Koryak Highlands and Kamchatka).
Status and Conservation. Not globally threatened. Fairly common to locally common; often common in appropriate habitat. Some indications that populations increasing in size. Breeds in areas with low human populations, and probably little affected by human activities. On wintering grounds,

in brushy areas, was in the past sometimes persecuted as an agricultural pest, but apparently this is no longer the case.

Bibliography. Anon. (1998), Beadle & Rising (2002), Bull (1988), Chesser & Zink (1994), Colwell (1999, 2000), Davis (1973), Garrett & Dunn (1981), Gerasimov (1997), Harris (1983), Hellmayr (1938), Hendricks (1987), Hoffman *et al.* (1991), Holmes & Dirks (1978), Howell & Webb (1995), Kazama (1987), Mattsson (2009), McCarthy (2006), Mewaldt & Farner (1957), Miller *et al.* (1957), Norment *et al.* (1998), Pearson (1979), Pyle (1997), Ralph & Vroman (1990), Ridgway (1901), Rising & Beadle (1996), Weckstein *et al.* (2001), Zink, Dittmann & Rootes (1991).

Genus *MELOSPIZA* S. F. Baird, 1858

63. Song Sparrow

Melospiza melodia

French: Bruant chanteur **German**: Singammer **Spanish**: Chingolo Cantor

Taxonomy. *Fringilla melodia* A. Wilson, 1810, Philadelphia, Pennsylvania, USA.

Genus generally considered to be closely related to *Passerella* and *Zonotrichia*; unpublished molecular studies suggest close relationship with *Xenospiza* and some of the grassland sparrows (*Passerculus*, some *Ammodramus*, *Pooecetes* and *Oriturus*). In molecular-genetic studies of present species, little concordance found between mitochondrial DNA patterns and geographical variation in plumage and morphology, suggesting rapid post-glaciation radiation, combined with plumage evolution that has occurred more quickly than changes in mitochondrial DNA. One of the most variable of all avian species, as many as 52 races have been named, many of them weakly differentiated. Proposed races considered insufficiently distinct include: *amaka* (described from Amak I, in extreme E Aleutians), which is synonymized with *sanaka*, *inexspectata* (from c. 4·8 km E of L Moose, in British Columbia), synonymized with *morphna*, *juddi* (from L Rock, Tower County, in North Dakota), *melanchra* (Bay Point, Ohio) and *euphonia* (Cranberry Glades, Pocahontas County, in West Virginia), all included within nominate; in California, *saltonis* (from margin of Salton Sea 1·6 km SE of Mecca), subsumed into *fallax*, *fisherella* (from L Honey, near Milford), subsumed into *montana*, *mailliardi* (from Ranchos Dos Rios, near Modesto, in Stanislaus County) and *cooperi* (from San Diego), both synonymized with *heermanni*, and *micronyx* (from San Miguel I), *clementae* (from San Clemente I) and *coronatorum* (from North I, in Los Coronados Is, off NW Baja California), all synonymized with *graminea*; also, in Mexico, *yuriria* (from Yuriria, in SE Guanajuato), treated as synonym of *adusta*, and *niceae* (from Tulancingo, in Hidalgo) and *azteca* (from Lago de Zumpango, in México), both subsumed into *mexicana*. Thorough taxonomic review required. Twenty-five subspecies currently recognized.

Subspecies and Distribution.

M. m. maxima Gabrielson & Lincoln, 1951 – W Aleutian Is (Attu I E to Atka I).

M. m. sanaka McGregor, 1901 – E Aleutian Is (Seguam I E to Unimak I and Amak I), Alaska Peninsula E to Stepovak Bay and islands S of peninsula (Sanak I E to Semidi Is).

M. m. insignis S. F. Baird, 1869 – Kodiak I and Alaska Peninsula at Kukak and Katmai; non-breeding also S along Alaskan coast.

M. m. kenaiensis Ridgway, 1900 – Alaska on Pacific coast of Kenai Peninsula and islands in Prince William Sound; non-breeding also S to British Columbia.

M. m. caurina Ridgway, 1899 – coast of N Gulf of Alaska; non-breeding also in Pacific Northwest S to NW California.

M. m. rufina (Bonaparte, 1850) – outer islands of Alexander Archipelago, in SE Alaska, and in Queen Charlotte Is, in British Columbia (Canada).

M. m. morphna Oberholser, 1899 – C & SW British Columbia S (W of Cascades) in NW USA to NW Oregon.

M. m. merrilli Brewster, 1896 – E British Columbia S in USA to SE Washington and NW Montana; non-breeding farther S (S to SE California).

M. m. cleonensis McGregor, 1899 – W of Cascades in SW Oregon and NW California.

M. m. gouldii S. F. Baird, 1858 – C coast of California (except San Francisco Bay), also Santa Cruz I.

M. m. samuelis (S. F. Baird, 1858) – San Pablo Bay and N San Francisco Bay, in California.

M. m. maxillaris Grinnell, 1909 – Suisun Bay, E of San Pablo Bay.

M. m. pusillula Ridgway, 1899 – S San Francisco Bay.

M. m. heermanni S. F. Baird, 1858 – C & SW California and extreme NW Mexico (NW Baja California); non-breeding S to SE California.

M. m. graminea C. H. Townsend, 1890 – Channel Is (San Miguel, Santa Rosa and Anacapa), off SW California (USA), and Los Coronados Is, off NW Baja California (Mexico).

M. m. montana Henshaw, 1884 – breeds in W USA throughout Rocky Mts and Great Basin from SE Washington E to NC Montana, S to N & E California and N New Mexico; non-breeding S to SE California and N Mexico (E Sonora E to Coahuila).

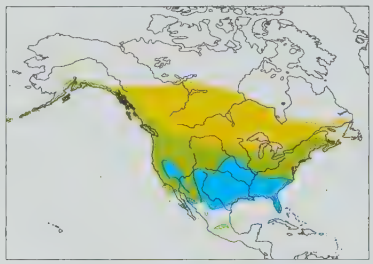
M. m. melodia (A. Wilson, 1810) – breeds from WC Canada (Prairie Provinces and E Great Plains) E to Newfoundland, and S in USA (except middle Atlantic coast) to N Georgia; non-breeding S to Florida and S Texas.

M. m. atlantica Todd, 1924 – breeds US Atlantic coast from Long I (New York) S to C North Carolina; non-breeding from Maryland S to Georgia.

M. m. fallax (S. F. Baird, 1854) – SW USA from S Nevada and SW Utah S, including E Mojave Desert and Sonoran Desert, to Gulf of California and SE Arizona.

M. m. rivularis W. E. Bryant, 1888 – S Baja California (from San Ignacio S to Sierra Laguna), in W Mexico.

M. m. goldmani Nelson, 1899 – W Durango (El Salto), in WC Mexico.



M. m. zacapu Dickerman, 1963 – Michoacán (Zacapu), perhaps also in Jalisco (at Laguna Chapala), in SW Mexico.

M. m. adusta Nelson, 1899 – R Lerma from L Yuriria (Guanajuato) S to Pátzcuero (Michoacán), in SC Mexico.

M. m. villai A. R. Phillips & Dickerman, 1957 – upper R Lerma drainage from Tarandacuao (Guanajuato) E to Toluca area (México), in SC Mexico.

M. m. mexicana Ridgway, 1874 – S Hidalgo, N México and Distrito Federal E to N Puebla and Tlaxcala, in SC Mexico.

Descriptive notes. 12–17 cm; 11·9–53 g. A medium-sized to large sparrow, largest in Aleutian Is and smallest in SW USA; rather long and rounded tail, often pumped up and down during flight. Nominate race has faintly dark-streaked dull brownish crown, narrow greyish-white median crownstripe, rather broad greyish-white supercilium extending posteriorly to side of nape, pale buffish eyering, narrow reddish-brown eyestripe behind eye, grey-buff lores and ear-coverts, latter bordered anteriorly by dark red-brown moustachial stripe, with contrasting whitish moustachial stripe and dark brown malar stripe; nape and side of neck greyish with faint dark streaking; upperparts greyish-brown with coarse black streaking (streaks with reddish-brown edges), rump olive-brown and faintly streaked, upper-tail-coverts greyer with stronger dark shaft streaks; tail feathers brown with slight rufous tinge, paler edges; lesser upperwing-coverts grey with rufous wash, rest of wing blackish-brown, edged warmer reddish-brown, median and greater coverts with narrow pale buff tips (forming two indistinct wingbars); throat and underparts whitish, breast and flanks boldly streaked dark rufous-brown, streaks often coalescing to form obvious small patch in centre of breast; iris dark reddish-brown; bill horn-coloured to grey, often dusky grey on culmen; legs yellowish-flesh to dusky brownish-grey. Sexes similar in appearance, male on average somewhat larger than female. Juvenile is generally more buffish in appearance than adult, has finely dark-streaked buff-brown crown with indistinct paler median stripe (sometimes lacking), underparts with somewhat thinner streaks, these not forming spot on breast. Races differ in size, bill size, and plumage coloration and markings, in broad terms NW races very large with large bill, plumage greyish with reddish streaking (juvenile has nearly uniform dark back), those from Pacific NW coast large, sooty or rusty, E races medium-sized and brownish, mainland California races relatively small and brownish-olive with blackish streaking below, races on Mexican plateau large and with dark brown/black ventral markings and white throat: *atlantica* is very like nominate, but tends to be slightly greyer and more distinctly streaked above; *montana* is slightly longer-tailed and longer-legged than nominate, but with slightly smaller bill, also a shade darker and greyer; *fallax* is clearly paler than previous and with paler rufous streaking; *maxima* is largest and biggest-billed of all races, plumage rather grey, streaks above and below dull rufous; *sanaka* is fairly large, olive-grey (in worn plumage looking ash-grey) with fairly heavy brown streaks above; *insignis* is slightly smaller than last, also upperparts darker and more uniformly brownish-grey; *kenaiensis* is smaller and browner than previous, with darker streaking; *morphna* is dark rufous-brown above, heavily streaked dark rufous below; *rufina* is larger, darker and more sooty-looking than previous; *caurina* is marginally larger and greyer than last; *merrilli* is somewhat darker and more uniform above than nominate, with less obvious streaking; *cleonensis* is more rufous in tone, with rufous-washed olive upperparts heavily streaked dark rufous-brown, rufous-brown streaks below becoming blackish at side of breast; *gouldii* is like previous, but less reddish above and with blacker (less rufous) streaks below; *heermanni* is relatively dark rufous above, with rather heavy blackish streaking both above and below; *samuelis* is very like last, but smaller and with slimmer bill; *maxillaris* tends to be darker brown above and more heavily streaked below than previous, also is larger and has bigger bill; *pusillula* is like *samuelis*, but smaller, more greyish-olive (less rufous) above and more heavily streaked (and often tinged yellowish) below; *graminea* is distinctly grey above and whitish below, with contrasting dark streaks; *rivularis* is pale, resembling *fallax*, but less rufous above, also larger and with longer, narrower bill; *goldmani* is like *montana*, but somewhat darker and less distinctly streaked above, also larger; *zacapu* is rather bright rufous above; *adusta* is similar to last, but slightly duller; *mexicana* is similar to *heermanni*, but darker, more olive-brown above, more heavily streaked and spotted below; *villai* is a large race, dark, more sooty and less rufous above than last. Voice. Song variable, but distinctive, characteristically starts with a series of 2–4 loud, clear whistles on same pitch, followed by a trill, often a buzzy trill, then several short notes, e.g. "chrup chrup chee chee tceeeee tzcu". Call a distinctive "tchenk", "tchip" or "chimp"; also a distinctive "tseep" call note.

Habitat. Open and semi-open areas with some cover. Generally on border of ponds or steams (invariably so in SW), or in old fields, thickets or woodland edge, or moist ravines. In Aleutian Is and coastal Alaska found in beach grass, commonly on boulder-strewn beaches, amid drift wood and boulders, and in winter feeding on tidal mudflats. In San Francisco Bay area (California) in saltmarsh and brackish marsh, and on both Pacific and Atlantic coasts in brackish marshes with cattails (*Typha*), cordgrass (*Spartina*), and pickleweed (*Salicornia*). In winter generally in brush, often near water. Sea-level to 2500 m.

Food and Feeding. Variety of foods. In British Columbia and NE, eats more plant food than animal food, but percentage of animal items increases during breeding season. Animal items include variety of insects, especially beetles (Coleoptera), Orthoptera, Lepidoptera, bugs (Hemiptera) and flies (Diptera), as well as earthworms (Annelida) and small gastropods. Plant foods consist of variety of seeds, e.g. millet (*Panicum*), wheat (*Triticum*), ricegrass (*Oryzopsis*), sunflowers (*Helianthus*), amaranth (*Amaranthus*), clover (*Trifolium*) and dock (*Rumex*), as well as fruits (e.g. *Vaccinium*, *Morus*, *Prunus*). Forages principally on or near ground or low in vegetation. Often in pairs or small groups, sometimes with other seed-eating species.

Breeding. Season varies geographically, generally Mar–Aug in W and Apr–Jul in E; two or three broods. Generally monogamous, but up to 13% of males and 21% of females at least occasionally mate in a polygamous group, depending on local density, sex ratio, and loss of mate. In migratory populations, males arrive at least a week before females, and begin to sing and defend a territory; pairs formed soon after females arrive, and nests built early, but egg-laying can be delayed by cold or wet weather. Nest built by female, a well-constructed cup of dry grass, plant stems, dry leaves and strips of bark, lining includes soft grasses, rootlets and sometimes hair, placed commonly on ground, under tuft of grass or shrub, sometimes as high as 4 m above ground in grass, shrub or tree. Clutch 1–6 eggs, usually 3–5, variably pale greyish, greenish or bluish with brown or rusty spots; incubation strictly by female, period 12–15 days, typically 13 days; chicks of first brood fed by both parents, later broods fed by female only; nestling period typically 10 days, although variable, and disturbance can cause young to leave early. Brood parasitism by Brown-headed Cowbird (*Molothrus ater*) very common (except in far N of range). Breeding success generally high; monogamous females have higher fledging success than those in polygamous groups; cowbird parasitism has negative and sizeable effect on reproductive success.

Movements. N populations generally migratory or partly migratory; S ones, including W coast populations as far N as Alaskan coast and islands, resident, but some populations partially migratory. Situation complex, but clearer and easier to understand in E, where N breeders all migratory; ring returns show that those breeding farthest N travel farthest S to winter quarters, a classic leapfrog pattern of migration. In E, migrates on NW–SE axis, concentrating in wintering areas in SE of USA; in W, much migration likely altitudinal, but in California presence of dark "Pacific Northwest" type individuals in winter suggests that some also perform significant N–S movements. In spring first departures from E wintering area from mid-Feb and last to mid-May, although peak migration mid-Mar to mid-Apr; reaches breeding areas in late Feb in S, Mar or Apr farther N, and May in Newfoundland. In W, spring passage noted between Apr and early May in Oregon; after breeding, begins to head S in Sept, with peak of movements at migration watchpoints from late Sept to early Nov, most in Oct. Arrives in wintering areas of far S, such as Sonora (Mexico), as early as mid-Sept; in SE wintering areas arrival begins in Sept, peak in mid-Oct, and some not

arriving until late Nov or early Dec. Accidental S to Bahamas and Dominican Republic. Vagrant to Russian Far East (Chukotka) and Japan; also to Europe, including British Is, Belgium, Netherlands and Norway.

Status and Conservation. Not globally threatened. Common to very common in much of range. In USA, populations on Santa Barbara I and San Clemente I, off W coast of California, have been extirpated by overgrazing of habitat, and populations in saltmarshes of San Francisco Bay, in California, have declined as a consequence of habitat loss. In desert areas of SW, overgrazing resulted in population declines. In California, races *samuelis*, *maxillaris*, *pusillula* and *graminea*, also "*mailliardi*" (subsumed in *heermanni*), are considered "of Special Concern". This species, however, responds well to conservation efforts that have reduced grazing in riparian habitats. In E North America, clearing of forests benefited this species by creating edge habitat for it. Although commonly parasitized by cowbirds, numbers of this emberizid remain high, suggesting that parasitism does not have a deleterious effect at population level (despite significant adverse effect on breeding success).

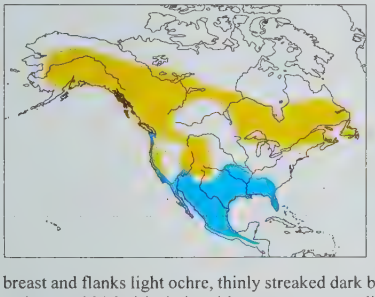
64. Lincoln's Sparrow

Melospiza lincolnii

French: Bruant de Lincoln **German**: Lincolnammer **Spanish**: Chingolo de Lincoln

Taxonomy. *Fringilla Lincolnii* Audubon, 1834, Labrador = near mouth of Natashquan River, Quebec, Canada.



Genus generally considered to be closely related to *Passerella* and *Zonotrichia*; unpublished molecular studies suggest close relationship with *Xenospiza* and some of the grassland sparrows (*Passerculus*, some *Ammodramus*, *Pooecetes* and *Oriturus*). Geographical variation of present species weak and clinal, and differences among populations obscured by individual variation; *alticola* often considered to be a synonym of nominate. Three subspecies provisionally recognized.

Subspecies and Distribution.

M. l. lincolnii (Audubon, 1834) – breeds from NW Alaska E through Canadian boreal forest (S from NC Yukon and C Northwest Territories) to Labrador, Newfoundland and Nova Scotia, and S in USA to C Washington, N Idaho, NW Montana, N Minnesota, N Wisconsin, C Michigan, W New York and C Maine; winters in region from S USA (S from N California, S Nevada and Arizona E to N Oklahoma, E Kansas, C Missouri, S Kentucky and N Georgia, also Florida) S to S Mexico and Guatemala, rarely S to Honduras, Panama and Greater Antilles.

M. l. gracilis (Kittlitz, 1858) – breeds coastal S Alaska and W Canada (C British Columbia, rarely Vancouver I); winters in SW USA (C California and Arizona) and NW & NC Mexico (Baja California, Sonora and Coahuila).

M. l. alticola (A. H. Miller & McCabe, 1935) – breeds in mountains of W USA from NC Oregon E to SC Montana and NC Wyoming, S to California (inner coastal ranges to San Jacinto Mts), WC Nevada, SW Utah, EC Arizona and N New Mexico; non-breeding from C California, Arizona and S Texas S through Mexico (except Yucatán Peninsula) to Guatemala and El Salvador (rare).

Descriptive notes. 11·5–14·5 cm; 14·3–24 g. A medium-sized sparrow; often pumps tail up and down during flight. Nominate race has crown brown to dark rusty brown, grey median crownstripe, supercilium and side of neck; ear-coverts brownish, outlined with darker brown, moustachial and malar stripes brown, submoustachial stripe buffy ochre; upperparts buffy olive, sharply streaked with black, rump olive and streaked brown; tail feathers greyish-brown; upperwing dark brown, sometimes slightly rusty edges on median and greater upperwing-coverts and tertials; chin and throat buffy white, thinly streaked with dark brown; breast and flanks light ochre, thinly streaked dark brown, sometimes with median breast spot; belly and vent whitish; iris dark red-brown; upper mandible mostly dark grey to dark horn-brown, lower mandible paler horn-coloured; legs pinkish-flesh to brownish. Sexes similar. Juvenile is like adult, but crown brown or greyish-brown and streaked, supercilium buffish to brownish, edges of upperwing-coverts and tertials buffy (sometimes somewhat rusty), with marking less pronounced. Races differ minimally in size (differences slight, and some overlap between races) and plumage, probably inseparable in the field: *gracilis* is marginally smaller than nominate, with greyish-brown upperparts, heavier streaking above and below; *alticola* is on average slightly larger than nominate, with upperparts very slightly darker. Voice. Song a rich warble similar to that of Northern House Wren (*Troglodytes aedon*); occasionally performs flight song. Call a sharp "tep" or "chip".

Habitat. Often in boggy sites with dense low willows (*Salix*), sedge (*Carex*) and in moss-dominated habitats, usually where dense low cover. At lower elevations often in dense willows, but sometimes in willows mixed with poplars (*Populus*) and small spruce (*Picea*) and tamarack (*Larix laricina*), and usually near bogs. In non-breeding season generally found in brush, often near water. Sea-level to 3000 m.

Food and Feeding. Feeds on a variety of foods. During breeding season mostly arthropods, such as insect larvae, and adult beetles (Coleoptera), flies (Diptera), homopteran bugs, Lepidoptera and mayflies (Ephemeroptera), as well as spiders (Araneae); also takes small seeds when available. In winter, primarily small seeds, but takes invertebrates if available. Forages principally on or near ground and low in vegetation; generally shy. Often in pairs or small groups, sometimes mixed with other species.

Breeding. Egg-laying from late May (mostly Jun and Jul), fledglings mid-Jun to mid-Aug; often two or more broods. Apparently monogamous. Usually in loose colonies of a few nests. Nest built by female, work requiring 3 days, a cup-shaped structure of dry grass, often sedges, lined with fine grass and sometimes hair, placed on ground, slightly elevated, often inside small willow shrub or birch (*Betula*) containing dense sedge cover, rarely in elevated branches. Clutch 3–5 eggs, commonly 4, variably off-white to pale bluish with darker brown or rusty spots and scrawls; incubation by female, period 10–13 days, typically 11 days; chicks fed by both parents, nestling period 10–11 days; second clutch may be initiated before first brood fledged. Nests parasitized rarely by Brown-headed Cowbird (*Molothrus ater*).

Movements. Migratory; in parts of W can be found in both summer and winter, although at different elevations, and possible that winter and breeding populations are of different individuals. Details of migration little known. In spring, passage in E begins middle to late Apr, peak in May, and ends in late May; in W migrates earlier, most having left wintering sites in California by mid-Apr. Departure from breeding grounds begins early Sept, and autumn migration peaks late Sept and early Oct, ending late Oct/early Nov through much of E; arrival in C California by early Sept, sometimes late Aug, suggesting earlier migration in W than in E. Arrival and departure in S Mexico (Oaxaca) late Nov and early May, respectively; in Costa Rica mid-Nov and late Feb. Generally three routes of travel: those breeding farthest W migrate mainly along lowlands W of Cascades–Sierra Nevada; mountain populations move through Great Basin; E populations migrate throughout, E of the mountains. Recorded as vagrant in Azores.

Status and Conservation. Not globally threatened. Common in W parts of range; uncommon to marginally rare in parts of E. In some areas of range habitat has been degraded by grazing of livestock. Reaches perhaps highest densities in subalpine meadows; nesting may be affected by recreational activities of humans.

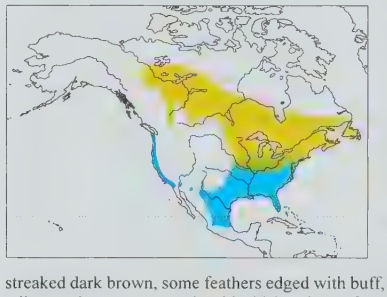
Bibliography. Allen (1967), Ammon (1995), Anon. (1998), Armani (1985), Beadle & Rising (2002), Caro *et al.* (2010), Cicero (1997), Cicero & Benowitz-Fredericks (2000), Dickey & van Rossem (1938), Gregorie & Gregorie (1996), Hellmayr (1938), Hofslund (1969), Howell & Webb (1995), Hubbard & Crossin (1974), Keith *et al.* (2003), Miller *et al.* (1957), Peck & James (1987), Pyle (1997), Ridgway (1901), Rimmer (1986), Rising & Beadle (1996), Sockman (2009), Speirs & Speirs (1968), Wortman-Wunder (1997), Zink (1982).

65. Swamp Sparrow

Melospiza georgiana

French: Bruant des marais **German**: Sumpfammer **Spanish**: Chingolo Pantanero

Taxonomy. *Fringilla georgiana* Latham, 1790, interior of Georgia, USA.



Genus generally considered to be closely related to *Passerella* and *Zonotrichia*; unpublished molecular studies suggest close relationship with *Xenospiza* and some of the grassland sparrows (*Passerculus*, some *Ammodramus*, *Pooecetes* and *Oriturus*). Race *nigrescens* rather distinctive, and apparently differs from others in ecology, migratory behaviour and nesting biology; further study required. Differences between *ericrypta* and nominate race slight. Three subspecies currently recognized.

Subspecies and Distribution.

M. g. ericrypta Oberholser, 1938 – breeds S Canada from SW Mackenzie E to C Quebec and Newfoundland and S to NE British Columbia, C Alberta, S Saskatchewan, W Ontario and SE Quebec, and S in USA to E North Dakota and N Minnesota; non-breeding from extreme SW Canada (coast of S Vancouver I) S in USA to CW California and C Nevada, also from E Texas E to S Georgia and NE Florida, and in Mexico in Sonora (rare) and Chihuahua, Coahuila and Tamaulipas S to Durango, Jalisco, San Luis Potosí and Veracruz.

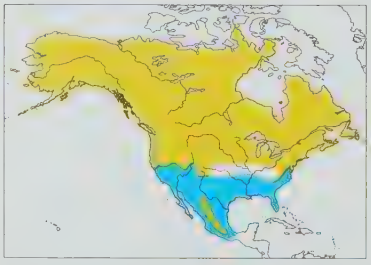
M. g. georgiana (Latham, 1790) – breeds from E South Dakota E to SE Canada (Prince Edward I and Nova Scotia), S to E Nebraska, N Missouri, Illinois, Ohio and West Virginia; non-breeding S to S Texas, Gulf Coast and S Florida.

M. g. nigrescens G. M. Bond & Stewart, 1951 – breeds coastal E USA (from New Jersey S to SE Maryland).

Descriptive notes. 12–15 cm; 13·1–24 g. A medium-sized sparrow; often pumps tail up and down during flight. Nominate race breeding has black forehead with short, narrow white median stripe above bill; crown rusty or dark brown (possibly differs with age or sex), bold grey supercilium, dark brown postocular stripe, grey to brownish-grey ear-coverts sometimes faintly outlined with ochre, thin dark moustachial stripe, pale submoustachial stripe, sometimes a thin dark malar stripe; chin and throat white or whitish, sometimes flecked with brown; nape greyish or greyish-brown; upperparts rusty, mantle and scapulars boldly streaked dark brown, some feathers edged with buff, rump and uppertail-coverts more rusty brown; tail rusty brown; upperwing blackish, edges of upperwing-coverts rusty (variable), some edged dark brown, tertials broadly edged rusty; breast greyish or greyish-brown, sometimes with faint thin streaking, flanks beige and thinly streaked, belly white, undertail-coverts whitish with brown centres; iris brown; upper mandible dark brown, lower mandible yellowish with brown tip; legs fleshy-pink to brownish. Non-breeding plumage is similar to breeding, but generally duller, crown browner and dark-streaked, often with narrow median stripe, side of head more buffish or brownish, breast with diffuse streaks. Sexes similar in plumage, but female tends to be less extensively rufous and more heavily streaked. Juvenile resembles adult, but crown blackish or darkly streaked, facial markings brown (rather than grey), usually some rusty in wing-coverts, underparts streaked. Race *ericrypta* is paler on upperparts than nominate, more greyish on back and rump, with pale dorsal feather edgings whiter and broader; *nigrescens* is distinctive, has larger bill, greyish plumage, and black on head and nape. Voice. Song a clear, slow liquid trill on single pitch, "weet-weet-weet-weet-weet-weet". Call a metallic "chink".

Habitat. Variety of habitats, from open cedar (*Chamaecyparis*) forests to bogs and freshwater marshes, and brackish tidal marshes on Atlantic coast (race *nigrescens*). In much of range nests in freshwater marshes or brush near water on pond margins with emergent vegetation such as cat-tail (*Typha*), bulrushes (*Scirpus*) and reed grass (*Calamogrostris*), with scattered willows (*Salix*) or alders (*Alnus*). In N, utilizes bogs with sedges (*Carex*), leatherleaf (*Chamaedaphne*), blueberry (*Vaccinium*) and sweet gale (*Myrica gale*). On migration and in winter found in thickets, often near water. Sea-level to 1800 m.

Food and Feeding. In breeding season mostly insects, but some fruit if available; race *nigrescens* probably eats more non-insect animal food than do other races. At other times of year diet includes insects, as well as seeds and fruit. Probably consumes more animal food items than do congeners. Forages principally on or near ground or low in vegetation, especially in reedbeds, also in shallow water; shy. Generally singly and in pairs; sometimes in small groups outside breeding season.
Breeding. Season late Apr to early Jul, mostly mid-may to early Jul; two broods common in S parts of range. Generally monogamous, but 10–20% of males bigamous in at least some years. Male begins territorial defence and advertisement through song immediately on arrival on breeding grounds; after female arrival, 1–2 weeks elapse before pair formation. Nest built by female alone, taking 3–4 days, a bulky cup with coarse exterior of dry grass, stems, sedges and similar material, soft inner lining of fine grasses, rootlets and hair, generally slightly elevated or above water and tending to be supported by emergent vegetation ranging from grasses to cat-tails; some nests on ground. Clutch 1–6 eggs, average c. 4, pale greenish or bluish with reddish-brown spots and blotches; incubation by female, period 12–14 days, typically 12 days; chicks fed by both parents, nestling period 9–11 days. Nests sometimes parasitized by Brown-headed Cowbird (*Molothrus ater*); appears to be poor host, as few cowbirds hatch.
Movements. Generally migratory; some perhaps resident in NE USA (N Iowa E to Massachusetts), where species present all year. Race *nigrescens* often cited as resident, but appears to be migratory, though wintering grounds not known. Recaptures of ringed individuals in different years at migratory sites suggest fidelity to traditional migratory routes, and some retrace routes in both directions; other data from coastal Atlantic sites and Florida suggest that more migrate along E route in autumn than in spring. In spring males migrate earlier than females; *nigrescens* arrives later in spring and leaves earlier in autumn than nominate migrants. Movement N from wintering areas begins early Mar, with peak early to mid-Apr, reaching breeding areas in S by mid-Apr, but late Apr in Minnesota and mid-May in C Alberta; *nigrescens* arrives in Maryland after 15th May. Autumn migration slower and lasts longer than spring migration: departure from breeding grounds from late Aug, most remaining to mid-Sept, peaks of passage over broad area spanning period from late Sept to mid-Oct; arrival on wintering grounds from mid-Oct to late Nov and even early Dec, males up to 2 weeks earlier than females.
Status and Conservation. Not globally threatened. Fairly common; often abundant in optimum habitat. Numbers greatly affected by loss of wetlands; a current decrease in populations is likely to continue.
Bibliography. Anderson (2009), Anon. (1998), Balaban (1988a, 1988b), Ballentine (2009), Ballentine *et al.* (2008), Beadell *et al.* (2003), Beadle & Rising (2002), Bond & Stewart (1951), Campbell *et al.* (2001), Cicero & Benowitz-Fredericks (2000), DuBois *et al.* (2009), Godfrey (1949), Greenberg (1988, 2003), Greenberg & Droege (1990), Greenberg, Cordero *et al.* (1998), Greenberg, Marra & Wooler (2007), Greenberg, Olsen & Etterson (2010), Hellmayr (1938), Howell & Webb (1995), Legare *et al.* (2000), Liu *et al.* (2008), Marler & Peters (1982, 1988a), Marler & Pickert (1984), Mowbray (1997), Nowicki *et al.* (2001), Okanoya & Dooling (1988), Olsen *et al.* (2008), Peck & James (1987), Peele *et al.* (2009), Podos, Nowicki & Peters (1999), Podos, Peters & Nowicki (2004), Poole *et al.* (2003), Pyle (1997), Reinert & Golet (1979), Ridgway (1901), Rimmer (1986), Rising & Beadle (1996), Russell & Monson (1998), Watts *et al.* (2008), Wetherbee (1968), Willson (1966b).



Genus *PASSERCULUS* Bonaparte, 1838

66. Savannah Sparrow

Passerculus sandwichensis

French: Bruant des prés **German**: Grasammer **Spanish**: Chingolo Sabanero
Other common names: Aleutian Savannah Sparrow (*sandwichensis*); Ipswich Sparrow (*princeps*); Dwarf Savannah Sparrow ("*brooksi*")

Taxonomy. *Emberiza sandwichensis* J. F. Gmelin, 1789, Unalaska, Alaska, USA.
Genus sometimes subsumed in *Ammodramus*. Traditionally treated as conspecific with *P. guttatus* and *P. rostratus*, and often also with *P. sanctorum*, but all differ in morphology and plumage and, to some extent, in ecology; separation at species level supported by recent molecular-genetic findings. Race *princeps* has been considered a separate species. Geographical variation of nominate race largely clinal: other proposed races are, from Canada, *anthinus* (described from Kodiak I, in Alaska), *crassus* (Sitka, in Alaska), *brooksi* (Chilliwack, in British Columbia), *oblitus* (Fort Churchill, in Manitoba) and *labradorius* (L'Anse-au-Loup, in Labrador), from USA *mediogriseus* (Ashtabula County, in extreme NE Ohio), *alaudinus* (from California, probably San Francisco), *nevadensis* (Soldier Meadows, Humboldt County, in NW Nevada) and *savanna* (Savannah, in E Georgia), from Mexico *rufofuscus* (Babicora, in Chihuahua) and *brunnescens* (Valley of Mexico), and from W Guatemala *wetmorei* (Hacienda Chancol); all are synonymized with nominate. Two subspecies recognized.
Subspecies and Distribution.
P. s. sandwichensis (J. F. Gmelin, 1789) – breeds in Alaska and Canada (except extreme N) S in USA to N California, W Colorado, Nebraska, Iowa, Indiana and N Georgia, in C Mexico S to Puebla, possibly also SW Guatemala, also in Russian Far East (Chukotka); non-breeding S Canada S to C Mexico.
P. s. princeps Maynard, 1872 – breeds Sable I, in E Canada (E Nova Scotia); winters on Atlantic coast of USA (E Massachusetts S to S Georgia).

Descriptive notes. 11·4–15·4 cm; 13–32·5 g. A rather small to medium-sized sparrow with relatively short, notched tail, geographically variable; tends to be larger on islands than on mainland, birds from Aleutian Is largest, size decreasing E along Alaska Peninsula. Nominate race has crown variably dark brown to grey-brown or buffish-brown, pale median crownstripe, generally yellowish supercilium (often paler posteriorly), dark eyestripe behind eye, dark moustachial stripe, whitish or light buffish submoustachial, dark brown malar stripe; chin and throat whitish, sometimes lightly spotted; nape and upperparts grey-buff to brown or grey-brown, mantle with heavy beige to blackish streaks, sometimes some thin rufous streaks, highly variable (generally paler in W than in E, darkest in NE, i.e. Labrador and Newfoundland, also darker in S); tail feathers dark brown with narrow paler edges; upperwing dark brown to blackish, feathers usually with pale rufous/buffish edges, median and greater coverts with whitish tips; underparts whitish to pale greyish-buff, breast and flanks heavily to lightly spotted/streaked, often an indistinct central breast spot; iris dark brown to dark red-brown; most of upper mandible dark greyish, lower mandible pinkish to horn-coloured; legs pink. Sexes alike. Juvenile is like adult, but tends to be more buffy. Race *princeps* is larger and paler than nominate, streaks below pinkish-brown and narrow. Voice. Song in breeding season a lisping "tzip-tzip-tzip streeeeeeeip", variable; race *princeps* slightly lower in pitch, with longer terminal trill. Calls include thin "seet", "chip", "tzip"; usually silent outside breeding season.
Habitat. Open areas, especially grasslands, generally with scattered shrubs, also tundra, meadows, farmland; in arid areas near water, often in grasses at edges of ponds. During migration also in urban parks.
Food and Feeding. In breeding season takes variety of larval, pupal and adult insects and other small invertebrates, e.g. spiders (Araneae), millipedes (Diplopoda), crustaceans, snails (Gastropoda); some seeds, but these a far less significant part of diet. On migration and in winter feeds principally on seeds and some fruits, as well as invertebrates when available. Small grass seeds and forbs make up more than 90% of diet in winter, *Digitaria*, *Ambrosia*, *Sorghum* and *Eleusine* predominating in some habitats; fruits include strawberries (*Fragaria*) and blueberries (*Vaccinium*). Forages on ground, sometimes (especially in autumn) in low bushes and trees. In non-breeding season occurs in small groups; often larger flocks during migration.
Breeding. Season mid-Feb to Aug, earlier in S and in coastal California than in N; usually two broods, sometimes three or more, but single-brooded at high latitudes. Female chooses nest-site, often at edge of or outside male's territory, she also constructs nest, a cup of woven grasses and other fine material, generally placed on ground, partly concealed with grasses and other vegetation, often at base of small bush. Clutch 2–6 eggs, usually 4–5, clutch size slightly larger at high latitudes than at low latitudes, eggs variable from off-white to pale greenish, with darker markings typically concentrated about wide end; incubation by female, period 9–15 days, usually c. 12 days; chicks fed by both parents, nestling period 8–13 days; fledglings stay with one parent for c. 15 days. Nests commonly parasitized by Brown-headed Cowbird (*Molothrus ater*).
Movements. Most populations migratory; some coastal California populations and those in Mexico and Guatemala resident. Commonly migrates at night, but some movements continue early in morning. In spring arrives from late Feb in S parts of breeding range, although most arrive early Mar; slightly farther N, in N USA and S Canada, arrival late Mar to early Apr, and does not reach N outposts until early May. Males and females may arrive together on breeding grounds, although on average males one week before females. From N breeding outposts in Alaska, moves S by middle to late Sept, and farther S & E, in Ontario and the Maritimes, departure by late Sept to mid-Oct. S of breeding areas passage early Sept to mid-Nov, and first arrivals by early Sept in Georgia and by late Sept in Florida; overall, S of Canadian border, migration peaks between early Oct and mid-Oct; in W moves through Oregon from late Sept to early Nov, so timing similar to that in E. Race *princeps* and populations of nominate race in Aleutian Is migrate earlier in spring and later in autumn than their smaller conspecifics: *princeps* leaves wintering grounds from mid-Mar to early Apr, arriving in Nova Scotia late Mar through early May, and in autumn starts to migrate in mid-Sept, most having departed from Nova Scotia by early Nov, though some apparently try to overwinter on Sable I; Aleutian birds reach Alaska by late Apr and breeding grounds by early May, and leave breeding grounds by late Sept. Rare migrant in El Salvador. Accidental on Cocos I, off Pacific coast of Costa Rica; also NE Russia (Wrangel I), Korea and Japan. Vagrant to British Is (nominate and race *princeps*) and Azores.
Status and Conservation. Not globally threatened. Often common or very common in appropriate habitat. Race *princeps* has tiny global range, a single small island c. 45 km long and 1 km wide, and small population; possibly at long-term risk from natural erosion of the island, which consists wholly of sand. This species moves into areas after clearance, logging or fires, and populations decline as woody vegetation replaces grassland. Thus in E North America, increased in abundance with the clearing of forests for farmland, but is decreasing as marginal farms abandoned, and as urban areas expand. In California, coastal breeding population ("*alaudinus*") is listed as being "of Special Concern" in the state owing to its low population size, restricted range, and decreasing habitat.

67. Belding's Sparrow

Passerculus guttatus

French: Bruant de Belding **German**: Beldingammer **Spanish**: Chingolo de Belding

Taxonomy. *Passerculus guttatus* Lawrence, 1867, San José del Cabo, Baja California Sur, Mexico.
Genus sometimes subsumed in *Ammodramus*. Traditionally treated as conspecific with *P. sandwichensis* and *P. rostratus*, and often also with *P. sanctorum*, but all differ in morphology and plumage and, to some extent, in ecology; separation at species level supported by recent molecular-genetic findings. Two additional proposed races from Baja California: *annulus*, described from Scammon's Lagoon (Guerrero Negro), is treated as a synonym of *beldingi*, and *magdalenae*, from North Estero (in Bahía Magdalenae), is synonymized with nominate. Two subspecies currently recognized.
Subspecies and Distribution.
P. g. beldingi Ridgway, 1885 – breeds extreme SW USA (coastal S California S from Santa Barbara, possibly from San Luis Obispo County) S in NW Mexico (Baja California), including Todos Santos I, to Laguna de Ojo Liebre.
P. g. guttatus Lawrence, 1867 – breeds in S Baja California from Laguna San Ignacio S to Bahía Magdalena; non-breeding S to Cabo San Lucas.
Descriptive notes. 11–14 cm; 15·5–22·5 g. Medium-sized sparrow, with relatively large bill. Nominate race is olive-grey above, with lemon-yellow supercilium fading behind eye, crown to back with dark brown streaks, tail dark brown and notched, upperwing feathers edged lighter brown; creamy-white submoustachial stripe, contrasting dark brown malar stripe; throat whitish, often flecked with brown, underparts white, breast and flanks streaked dark brown; iris dark; bill pinkish to horn-coloured, upper mandible often mostly dark horn-brown; legs pink. Differs from rather

similar *P. sandwichensis* mainly in darker general coloration, tendency to lack pale median crownstripe. Sexes similar. Juvenile is like adult, but perhaps buffier. Race *beldingi* is similar to nominate, but on average smaller in size and with smaller bill (but considerable overlap in dimensions), also darker general coloration and more intense yellow in supercilliary stripe. Voice. Primary song a highly variable, rather unmusical series of high-pitched chips and buzzes, often a "tzip tzip tzip zipppppppppp ip"; some versions have more emphatic ending, a "tick-a-see" note, than song of *P. sandwichensis*. Alarm "tsip"; also an intraspecific agonistic note, a loud buzz.

Habitat. Coastal saltmarshes with pickleweed (*Salicornia*), *Allenrolfea*, sea blight (*Suaeda*), alkali heath (*Frankenia grandifolia*), *Batis maritima*, *Monanthochloe*, *Atriplex*, *Triglochin*, and saltgrass (*Distichlis*); found in xeric scrub on Todos Santos I. After breeding, sometimes moves out of marsh and forages along beach strand and adjacent weedy areas.

Food and Feeding. Feeds on a variety of decapods, especially fiddler crabs (*Uca*), also isopods and amphipods, as well as on probable *Salicornia* seeds, also on adult and larval insects and small molluscs. Forages on ground and low in vegetation.

Breeding. Season mid-Feb to early Jun, mostly Apr and early May, and by mid-May most first broods have hatched; probably generally double-brooded. Possibly colonial nester, or at least nests quite densely packed in saltmarsh habitats. Nest made with dried *Salicornia* and *Distichlis*, also other vegetation, lined with finely woven grasses and fibres, including horsehair, placed on ground or close to it (to 15 cm up), often in saltgrass and in shelter of *Salicornia* or other taller vegetation; on Todos Santos I may be placed in low shrub. Clutch 3 eggs, rarely 4, pale blue with brown spots and blotches; no information on incubation and nestling periods. Nests susceptible to high water levels, such as those caused by storm tides.

Movements. Apparently sedentary. Some post-breeding movement to nearby beach strand; perhaps a certain amount of post-breeding wandering, and dispersal by juveniles at this time.

Status and Conservation. Not globally threatened. Locally common. Has suffered much loss of habitat to residential and recreational development, particularly in California, where now listed as a "State Endangered Species", as a consequence of the great reduction in saltmarshes.

Bibliography. Bradley (1977, 1994), Burnell (1998), Davis *et al.* (1984), Goldstein *et al.* (1990), McCarthy (2006), Omel'ko (1974), Powell (1993), Pyle (1997), Rising (1987a, 1987b, 1988, 2001, 2007, 2010), Rising & Beadle (1996), Rising *et al.* (2009), van Rossem (1947), Taber (1968b, 1968d), Wheelwright & Rising (1993), Williams & Hansell (1981), Zink *et al.* (2005).

68. Large-billed Sparrow

Passerculus rostratus

French: Bruant du Sonora **German**: Kalifornienammer **Spanish**: Chingolo Picudo

Taxonomy. *Emberiza rostrata* Cassin, 1852, seashore at San Diego, California, USA.

Genus sometimes subsumed in *Ammodramus*. Traditionally treated as conspecific with *P. sandwichensis* and *P. guttatus*, and often also with *P. sanctorum*, but all differ in morphology and plumage and, to some extent, in ecology; separation at species level supported by recent molecular-genetic findings. Geographical variation of present species apparently clinal, but difficult to determine as populations not distributed continuously along coast. Two subspecies recognized.

Subspecies and Distribution.

P. r. rostratus (Cassin, 1852) – breeds in NE Baja California (delta of R Colorado, San Felipe) and NW Sonora (mouth of R Colorado S to Patos I), in NW Mexico; non-breeding N to extreme SW USA (Salton Sea, Santa Cruz and Channel Is, all in S California) and on both shores of Baja California S to Cabo San Lucas.

P. r. atratus van Rossem, 1930 – breeds from coast of Sonora (Tepopa Bay and Kino Bay) S to C Sinaloa (El Molino); non-breeding individuals perhaps wander to extreme S Baja California.

Descriptive notes. 13–14·5 cm; 21–25·2 g. Medium-sized sparrow with large bill. Nominate race is light greyish-brown above, crown flecked blackish and with indistinct median crownstripe, mantle and back diffusely streaked darker brown; pale beige or pale yellowish supercilium and whitish submoustachial stripe; tail feathers brown, edged paler; upperwing blackish-brown, feathers edged light rufous, tips of median and greater coverts whitish (forming two wingbars); pale or rusty brown malar stripe, whitish throat, often flecked with brown, whitish underparts washed light buff, breast and flanks streaked rusty beige or brown; iris dark; bill flesh-coloured to yellowish-horn, dark culmen; legs pink. Distinguished from *P. sandwichensis* and *P. guttatus* mainly by larger and in particular longer bill, also diffuse nature of upperpart pattern and overall pale coloration. Sexes similar. Juvenile resembles adult. Race *atratus* is darker than nominate. Voice. Primary song a variable, rather unmusical series of high-pitched chips and buzzes, often as "tzip tzip tzip zipppppppppp ip". Alarm "tsip"; also has an intraspecific agonistic note, a loud buzz. Vocalizations differ from those of *P. guttatus*, but are similar.

Habitat. Coastal saltmarshes with pickleweed (*Salicornia*), *Allenrolfea*, sea blight (*Suaeda*), alkali heath (*Frankenia grandifolia*), *Batis maritima*, *Monanthochloe*, *Atriplex* and *Triglochin*.

Food and Feeding. Variety of decapods, especially fiddler crabs (*Uca*), also isopods and amphipods, as well as *Salicornia* seeds (probable), adult and larval insects, and small molluscs. Forages on ground and low in vegetation.

Breeding. Breeds mid-May through early Jun, mostly in May. Nest made from dried *Salicornia* and saltgrass (*Distichlis*) and other vegetation, lined with finely woven grasses and fibres (little difference between outer wall and lining), commonly placed in saltgrass, close to ground (up to 15 cm up), and often in shelter of *Salicornia* or other taller vegetation. Clutch 3 eggs, rarely 4, whitish to pale blue with dark spots and blotches; no information on incubation and nestling periods. Nests susceptible to high water levels, such as those caused by storm tides.

Movements. Some individuals breeding along coast of N Sonora wander in post-breeding season, many moving N to S California (especially Salton Sea and Pacific coast); winter vagrant as far N in California as Marin County (N San Francisco Bay area).

Status and Conservation. Not globally threatened. Common to abundant; local in occurrence. Habitat greatly reduced through residential and recreational development. In California listed as "Species of Conservation Concern", in second highest order of priority, because of steep declines in its numbers following major changes to environment of Colorado River Delta.

Bibliography. Anthony (1906), Garrett (1994), Grinnell (1905), Johnson & Ohmart (1973), McCarthy (2006), Pyle (1997), Ridgway (1901), Rising (1988, 2001, 2007, 2010), Rising & Beadle (1996), Rising *et al.* (2009), van Rossem (1947), Shuford & Gardali (2008), Taber (1968e), Wheelwright & Rising (1993), Zink *et al.* (2005).

69. San Benito Sparrow

Passerculus sanctorum

French: Bruant des San Benito **German**: Benediktammer **Spanish**: Chingolo de las San Benito

Taxonomy. *Passerculus sanctorum* Coues, 1884, Isla San Benito, Baja California, Mexico.

Genus sometimes subsumed in *Ammodramus*. Traditionally treated as conspecific with *P. sandwichensis*, *P. guttatus* and *P. rostratus*, and apparently most closely related to *P. guttatus*, but all differ in morphology and plumage and, to some extent, in ecology; present species almost certainly reproductively isolated from those, and separation at species level supported by recent molecular-genetic findings. Monotypic.

Distribution. San Benito Is, off CW Baja California, in extreme NW Mexico.

Descriptive notes. 12–13·7 cm; 19·4–24 g. Medium-sized sparrow, relatively large-bodied and with large, stout bill deep at base. Plumage is greyish-brown above, crown mottled brown and with no median crownstripe, mantle and back with darker feather centres; dirty whitish supercilium, whitish submoustachial stripe; tail feathers brown, edged paler; upperwing blackish-brown, feathers edged lighter, tips of median and greater coverts whitish (forming two indistinct wingbars); brown malar stripe, throat white, spotted dark brown, whitish below, breast and flanks streaked brown; iris dark; bill horn-coloured, lower mandible paler; legs pinkish to brownish. Sexes similar. Juvenile resembles adult. Voice. Song not described, apparently like that of *P. guttatus*. Calls include "tsip".

Habitat. Xeric scrub; coastal desert-thorn (*Lycium californicum*), known also as "frutilla", a prominent plant in this species' environment, and apparently exploited extensively. Forages also along beach.

Food and Feeding. Feeds extensively on fruit of *Lycium* when this available; probably also takes variety of small arthropods. Also eats rice when offered, and accepts table scraps from humans. Forages on ground and low in vegetation; searches among tidewrack along beach.

Breeding. Eggs late Mar or early Apr, recently fledged young seen late Apr (in 1906), and one young seen on nearby Cedros I on 21st Apr; no evidence of nesting in late Apr in 1999, suggesting that timing may vary from year to year. Nest composed of grasses, lined with finer grasses and few feathers, placed on or near ground under small bush and sunk level with ground or placed up to c. 0·3 m up in low bush. One clutch contained 3 eggs, pale with dark spots. No other information.

Movements. Resident; possibly some limited dispersal.

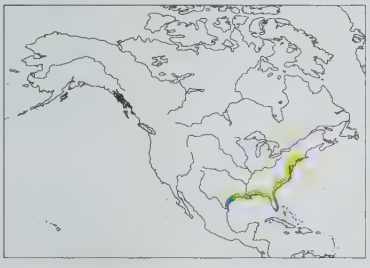
Status and Conservation. Not globally threatened. Abundant where found; local. Has very small global range, restricted to three small islands, rendering it potentially vulnerable. May be threatened also by accidental introduction of deer mice (*Peromyscus*). Can become rather tame; readily interacts with human inhabitants of a small fishing village on the islands, accepting food scraps from them.

Bibliography. Rising (1988, 2001, 2007, 2010), Rising & Beadle (1996), Rising *et al.* (2009), van Rossem (1947), Taber (1968c), Wheelwright & Rising (1993), Zink *et al.* (2005).

PLATE 47

inches 2

cm 5



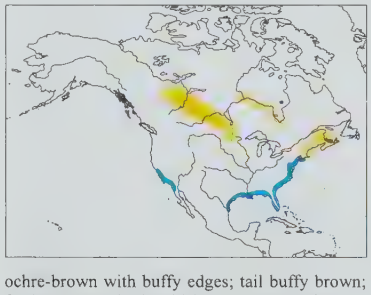
Genus *AMMODRAMUS* Swainson, 1827

70. Seaside Sparrow

Ammodramus maritimus

French: Bruant maritime **German**: Strandammer **Spanish**: Chingolo Costero
Other common names: Common Seaside Sparrow (*maritimus*); Dusky Seaside Sparrow (extinct race *nigrescens*); Cape Sable Seaside Sparrow (*mirabilis*)

Taxonomy. *Fringilla maritima* A. Wilson, 1811, Great Egg Harbor, New Jersey, USA.
Genus, as currently delimited, is probably polyphyletic. Molecular studies suggest that this species is in a clade with *A. nelsoni*, *A. caudacutus* and *A. leconteii*; hybrid with *A. caudacutus* has been described. Distinctive races *mirabilis* and recently extinct *nigrescens* have been considered to represent two further species. Otherwise, races along Atlantic coast not well marked, nor are those on Gulf of Mexico, but the two groups are clearly different from each other; racial differences, however, confused by individual variation and plumage dichromatism (buffy and grey morphs). Seven extant subspecies recognized.
Subspecies and Distribution.
A. m. maritimus (A. Wilson, 1811) – breeds coastal E USA from New Hampshire and Massachusetts S to extreme N North Carolina; non-breeding S to NE Florida.
A. m. macgillivraii (Audubon, 1834) – North Carolina S to extreme SE Georgia.
A. m. sennetti J. A. Allen, 1888 – coastal S Texas (from Aransas County S to Nueces Bay); winters S to mouth of R Grande and to extreme NE Mexico (NE Tamaulipas).
A. m. fisheri Chapman, 1899 – San Antonio Bay (Refugio County), in SE Texas, E to SW Alabama; non-breeding SW to Nueces County, in Texas.
A. m. juncicola (Griscom & Nichols, 1920) – coastal NW Florida from Escambia County E to Taylor County.
A. m. peninsulae J. A. Allen, 1888 – W Florida from about Dixie County S to Old Tampa Bay.
A. m. mirabilis (A. H. Howell, 1919) – SW Florida from vicinity of Everglades SE (formerly) to Cape Sable.



Descriptive notes. 12·5–15 cm; 18·9–28·7 g. A small sparrow with rather long and narrow conical bill, and relatively short tail with "sharp" rectrices. Nominate race has largely grey head with yellow supraloral patch (sometimes extended posteriorly into short supercilium), whitish submoustachial stripe, dark malar stripe and whitish throat; upperparts greyish with some brownish streaking (can look unstreaked); tail brownish; upperwing contrastingly brownish, greater upperwing-coverts mostly rufous; underparts greyish, breast and lower flanks washed buff, weak to moderately strong grey-brown streaking on breast and flanks; iris dark brown; bill leaden-grey with dusky grey culmen; legs dull brownish-grey. Sexes similar. Juvenile has olive-brown crown and upperparts streaked dark brown, mantle feathers with pale edges, face pattern like adult, with supraloral stripe pale buffish (rather than yellow), underparts light buff-white, breast and flanks more strongly buff and with thin brown streaks; first-winter like adult, but may be somewhat buffier. Race *macgillivraii* is similar to nominate, but smaller and more noticeably streaked; *mirabilis* is rather small, plumage tinged olive above, conspicuously streaked below; *peninsulae* has dark back, and breast somewhat more heavily streaked; *juncicola* is marginally larger than previous, also darker and browner; *fisheri* is whitish below with bright buff tinge around ear-coverts and on breast to flanks; *sennetti* is greenish-grey and unstreaked above, greyish-white below, with buff breastband and yellowish breast, juvenile unstreaked below; recently extinct race *nigrescens* was the darkest and most contrasted race, upperparts and side of head mostly black, contrasting with yellow supraloral patch, underparts white with bold, broad black streaks. Voice. Song a buzzy "spitsh-sheer, tup tup zee eeeee", or "oka-chee weeee", sounding like faint Red-winged Blackbird (*Agelaius phoeniceus*). Call "chak".
Habitat. Edge and interior of saltmarsh in most of range; occupies wettest, muddiest parts of marsh, nesting in vegetation consisting chiefly of cordgrass (*Spartina*), blackgrass (*Juncus gerardii*), cat-tail (*Typha*) and marsh-elder (*Iva annua*). In S Florida, race *mirabilis* breeds in freshwater habitats, especially in sparse sawgrass (*Cladium jamaicense*) or *Muhlenbergia* grass prairies, in which commonest three years after fire.
Food and Feeding. Largely animal matter, which accounts for more than 80% of diet in some places. Eats marine insects, small snails (Gastropoda) and crabs (Decapoda), beetles (Coleoptera); in winter more vegetable matter, mainly seeds of marsh grasses. Along New York coast, also takes adult and larval soldier flies (Stratiomyidae), shore flies/brine flies (Ephydridae), plant bugs (Miridae), and horseflies (Tabanidae). Nestling diet includes soft-bodied insects, e.g. moths (Lepidoptera). Forages mostly on ground, tending to keep close to cover. Catches some insects in air, and apparently also probes in mud for food. Usually in pairs; outside breeding season also in small groups.
Breeding. Season late Mar to Aug; some pairs double-brooded. Monogamous. Nest built by female alone, a cup of dry grasses, lined with finer grasses, suspended by grass stems in blackgrass tussock, cordgrass or marsh-elder, usually close to ground just above high-tide line, generally 14–71 cm above water, placement dependent on available marsh grass. Clutch 3–6 eggs, usually 4 or 5, whitish to pale blue with brown splotching, marks thickest at wide end; incubation by female, period 12 days; chicks fed by both parents, nestling period 9 days.
Movements. S populations sedentary. N populations (nominate race) move S to wintering grounds from Virginia to NE Florida, some occasionally remaining N as far as Massachusetts. S-bound movements begin by late Aug, peak later, continuing into late Oct; tower kills inland (up to 180 km from coast) suggest that some may move S away from immediate coast, or are displaced by winds during migration; N populations migrate back to breeding areas by late Apr, males arriving a week before females. Some movement N into Canadian Maritimes noted between late Aug and late Oct, possibly involving post-breeding wanderers.
Status and Conservation. Not globally threatened. Classified as "Highest Concern" in the USA (Red WatchList priority species for conservation). Race *mirabilis* protected under the Endangered Species Act in USA since 1973. This species can be common in suitable habitat. Estimated total population c. 110,000 individuals. Numbers declining, and many local populations have been extirpated by habitat loss, pesticide use, and development. Race *nigrescens* of CE Florida (a few sites from N Brevard County S to Titusville and Merritt I) extinct since 1987; heavily affected by measures aimed at mosquito control, first through DDT spraying and subsequently by flooding of marshland; ultimately, draining of marshes for road construction, combined with pesticides and pollution eliminated this race. Possible race *pelonotus* (perhaps no more than an isolated population of race *macgillivraii*) extinct since mid-1970s; formerly found in NE Florida (from Georgia–Florida boundary S to New Smyrna). In 2007 race *mirabilis* population c. 3184 individuals, largely within Everglades National Park and adjacent Big Cypress National Preserve; this is less than 50% of numbers in early 1990s, before hurricane "Andrew" struck, in 1992. Conservation initiatives for this race include efforts to restore water flows, and controlled burns at intervals of five to ten years. In general, the future viability of this species depends also on protection of large remaining tracts of undiked saltmarshes. Potential effects of climate change need also to be considered. It is not parasitized by Brown-headed Cowbird (*Molothrus ater*).
Bibliography. Almario *et al.* (2009), Anon. (1998), Avise & Nelson (1989), Baynard (1932), Beadle & Rising (2002), Bent & Austin (1968), Boulton & Lockwood (2010), Boulton, Baiser *et al.* (2011), Boulton, Lockwood *et al.* (2009), Curnutt *et al.* (1998), David & Gosselin (2002a), Elderd & Nott (2008), Gabrey & Afton (2000), Gjerdrum *et al.* (2005), Graves (1981), Greenlaw & Post (1985), Hill & Post (2005), Jenkins *et al.* (2003), Kale (1983), La Puma *et al.* (2007), Lebbin *et al.* (2010), Lockwood *et al.* (1997), Marshall & Reinert (1990), McCarthy (2006), McDonald (1989), McDonald & Post (1982), Nelson *et al.* (2000), Phillips & Einem (2003), Post & Greenlaw (1995, 2000, 2006), Poulson (1969), Quay *et al.* (1983), Rakestraw & Baker (1982), Rising & Beadle (1996), Tracey & Greenlaw (2009), Walters *et al.* (2000), Woolfenden (1956), Zink & Kale (1995).

71. Nelson's Sparrow

Ammodramus nelsoni

French: Bruant de Nelson **German**: Nelsonammer **Spanish**: Chingolo de Nelson
Other common names: Nelson's Sharp-tailed Sparrow; Sharp-tailed Sparrow (when treated as conspecific with *A. caudacutus*)

Taxonomy. *Ammodromus* [sic] *caudacutus nelsoni* J. A. Allen, 1875, Calumet Marshes, Cook County, Illinois, USA.
Genus, as currently delimited, is probably polyphyletic. Molecular studies suggest that present species is in a clade with *A. maritimus*, *A. caudacutus* and *A. leconteii*; has hybridized with *A. leconteii*. Until recently considered conspecific with *A. caudacutus*, but differs in its natural history; the two hybridize in NE USA (S Maine and N Massachusetts); precise ranges of the two on Atlantic coast not fully known, as references to "Sharp-tailed Sparrow" not always clear. Distinctive race *subvirgatus* perhaps represents a distinct species; further study needed. Race *alter* poorly differentiated from nominate. Three subspecies provisionally recognized.
Subspecies and Distribution.
A. n. nelsoni J. A. Allen, 1875 – breeds in Canada from NE British Columbia and S Mackenzie SE through Alberta to C & S Saskatchewan and C Manitoba, and in N USA in N, W & SE North Dakota, NE South Dakota and NW Minnesota; winters on Pacific coast of SW USA (California) and in extreme NW Mexico (N Baja California) and on Gulf Coast from Texas E to Florida Panhandle, also rarely S to Tamaulipas (NE Mexico).
A. n. alter (Todd, 1938) – breeds in EC Canada from N Manitoba E to N Ontario and W Quebec; probably winters on Gulf Coast of USA (W to Texas).
A. n. subvirgatus Dwight, 1887 – breeds in SE Canada (S side of St Lawrence R in S Quebec E to New Brunswick, Prince Edward I and Nova Scotia), and in NE USA S to S Maine and N Massachusetts; non-breeding on Atlantic coast S to South Carolina and N Florida, casually N to New York.

Descriptive notes. 11–13·5 cm; 12·8–20 g. A fairly small sparrow, short tail having spike-like rectrices. Nominate race has broad grey median crownstripe (not sharply defined) outlined by two dark brown lateral crownstripes, all extending back onto nape, hindneck grey with variable brown centre; broad yellow-ochre supercilium, wedge-shaped blackish eyestripe narrow at eye; ear-coverts greyish-ochre, thinly edged brown, ochre submoustachial stripe and postauricular area; mantle and upper back brown to greyish-brown with whitish stripes (in worn plumage stripes can be obscure), lower back and rump feathers dark ochre-brown with buffy edges; tail buffy brown; lesser upperwing-coverts dark olive-grey, wing feathers otherwise blackish-brown with rufous edges, these broadest on greater coverts and tertials; throat pale buffish; breast and flanks ochre, streaked brown, belly white, undertail-coverts buffy; iris dark brown; bill pinkish to leaden-grey, broadly dark horn-brown on culmen; legs flesh-coloured. Sexes similar in coloration. Juvenile has blackish crown, broad orange-buff median crownstripe and supercilium, brown mantle and scapular feathers edged buff (forming streaks), rump and uppertail-coverts unstreaked, throat and underparts mostly orange-buff, variously streaked, belly and vent paler. Race *alter* is very like nominate, but perhaps duller; *subvirgatus* is somewhat larger than others, and noticeably greyer in coloration, juvenile has median crownstripe olive-buff, rump slightly streaked. Voice. Song, often in aerial display and often at night, likened to sound made by water dropping on to a hot skillet, "psdhee-zipt" or "pshhh'tpt", c. 1 second in duration. Call a sharp "tsick" or "chip".
Habitat. Breeds in wet freshwater grasslands, sometimes mixed with cat-tail (*Typha*) and *Phragmites* reeds, and in sedge (*Carex*) marshes, often interspersed with small trees or bushes. In winter found in rank tall grasses, damp weedy fields and cat-tails, and in overgrown short-grass prairie; on migration often in cat-tail marshes, sometimes in salt or brackish marshes. Occurs from sea-level up to 1100 m.
Food and Feeding. In breeding season feeds almost exclusively on animal material, especially larval insects, spiders (Araneae) and amphipods, augmented with seeds of grasses such as wild rice

On following pages: 72. Saltmarsh Sparrow (*Ammodramus caudacutus*); 73. Le Conte's Sparrow (*Ammodramus leconteii*); 74. Baird's Sparrow (*Ammodramus bairdii*); 75. Henslow's Sparrow (*Ammodramus henslowii*); 76. Grasshopper Sparrow (*Ammodramus savannarum*); 77. Grassland Sparrow (*Ammodramus humeralis*); 78. Yellow-browed Sparrow (*Ammodramus aurifrons*); 79. Sierra Madre Sparrow (*Xenospiza baileyi*).

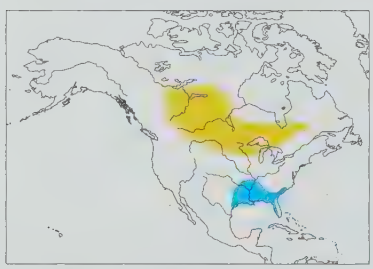
(*Zizania aquatica*); diet at other times also principally animal matter, augmented with seeds. Forages mostly on or near ground and low in vegetation. Generally secretive.
Breeding. Season late May to mid-Aug; race *subvirgatus* sometimes double-brooded. Promiscuous and non-territorial; does not form pair bonds. Possibly loosely colonial. Often performs elaborate aerial display while singing. Nest a loosely built cup (details not available) built in grass column, supported by vegetation on all sides, can be quite low above water (average 5 cm up), though sometimes to 25 cm above surface. Clutch 2–6 eggs, usually 3–5, pale greenish with reddish-brown speckling; incubation of eggs and feeding of chicks by female alone, no information on duration of incubation and nestling periods. Nests parasitized extremely rarely by Brown-headed Cowbird (*Molothrus ater*).
Movements. Migratory. Very difficult to detect during migration, and much remains to be learnt regarding movements; spring and autumn migration routes expected to be similar. Individuals of nominate race wintering in S USA (Texas coast) depart from Apr, most having left wintering areas by late May, and move N along Mississippi R lowlands, and those wintering in SE move towards NW in spring; most do not reach Canadian Prairies until May, most arriving by late May, and earliest in middle to late Apr. In autumn most move S along Mississippi lowlands to Gulf Coast, but some appear to head SE to Atlantic coast and move S along coastal marshes. Migration of race *alter* little known: perhaps most that migrate through S Ontario and upstate New York are of this population; few specimens known from farther W, in Michigan and Ohio; probably winters on Gulf Coast; in Ontario spring migration nearly non-existent, while autumn movements reach peak in mid-Oct. Coastal *subvirgatus* simply moves N and S along Atlantic coast: arrival on breeding grounds late May to early Jun, and post-breeding movement spans period from early Oct to early Dec; in warm winters, some may remain on breeding grounds well into Dec, sometimes moving S when harsher weather sets in.
Status and Conservation. Not globally threatened. Classified as "Rare" in the USA (Yellow WatchList priority species for conservation). Often common locally in appropriate habitat. Global population estimated at c. 510,000 individuals. In Canada, may be declining in the Maritimes owing to habitat loss. Nominate race formerly bred in Illinois (N USA). Main threats are loss, degradation and fragmentation of marshland areas as a result of draining, conversion to agriculture, and coastal development, and also invasive *Phragmites*; predicted sea-level rise caused by climate change would further reduce and fragment coastal habitats. Environmental contaminants may pose a series of problems, e.g. high levels of mercury found in some blood samples taken from this species.

(1996), Tracey & Greenlaw (2009), Zink & Avise (1990).

72. Saltmarsh Sparrow
Ammodramus caudacutus

French: Bruant à queue aiguë **German**: Spitzschwanzammer **Spanish**: Chingolo Colifino
Other common names: Saltmarsh Sharp-tailed Sparrow; Sharp-tailed Sparrow (when treated as conspecific with *A. nelsoni*)

Taxonomy. *Oriolus caudacutus* J. F. Gmelin, 1788, New York, USA.
Genus, as currently delimited, is probably polyphyletic. Molecular studies suggest that present species is in a clade with *A. maritimus*, *A. nelsoni* and *A. leconteii*. Until recently considered conspecific with *A. nelsoni*, but differs in its natural history; the two hybridize in NE USA (S Maine and N Massachusetts); precise ranges of the two on Atlantic coast not fully known, as references to "Sharp-tailed Sparrow" not always clear. Races poorly differentiated, and probably indistinguishable in the field; original description of *diversus* was based on material from S of species' breeding range. Two subspecies tentatively recognized.
Subspecies and Distribution.
A. c. caudacutus (J. F. Gmelin, 1788) – breeds NE USA from S Maine S along coast to New Jersey; non-breeding mainly from New Jersey S to N & W Florida.
A. c. diversus Bishop, 1901 – breeds from coastal New Jersey S to Delmarva Peninsula; non-breeding probably from breeding range S to NE Florida, and casually to Louisiana.



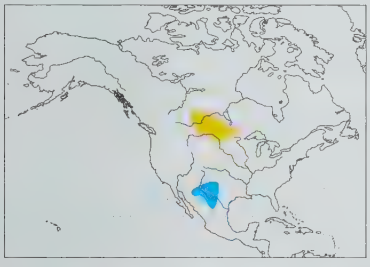
Descriptive notes. 11·5–13 cm; 15·3–23·1 g. A fairly small sparrow with short tail, rectrices spike-like. Nominate race has grey median crownstripe thin and often indistinct, bordered by two dark brown lateral crownstripes, with orange-buff to yellow-orange supercilium, submoustachial stripe and postauricular stripe; ear-coverts and nape grey; mantle and upper back greyish with white streaking (in worn plumage streaks obscure), lower back, rump and uppertail-covert feathers brown with buffy edges; tail buffy brown; lesser upperwing-coverts olive-grey, wing feathers otherwise mainly blackish, median upperwing-coverts brown with broad blackish centres and buffy tips, greater coverts and tertials blackish on centres, buff to whitish fringes on tips becoming rufescent brown and much broader towards feather bases, primaries and secondaries with narrow rufescent brown to pale buffy edges; throat white; breast and flanks pale buff with blackish-brown streaks, belly white, undertail-coverts pale buffish with some blackish streaks on shorter ones; iris dark brown; bill dark horn above, paler below; legs flesh-coloured. Sexes similar in coloration. Juvenile fairly similar to adult, but buffy in hue and with underparts more extensively, although finely, streaked. Race *diversus* is very similar to nominate, but bill on average slightly smaller, and upperparts perhaps darker. Voice. Male has a "whisper song" that has a whispery, wheezy quality, and may last for more than one minute, "ts-ts-sssss-tsik" or "si-lik tssss-s-s-s-s". Call is a sharp "chic", and also a repeated series of "tsick", "chuck" or "chip" notes.
Habitat. Occupies saltmarshes and wet meadows with dense cordgrass (*Spartina alterniflora*), blackgrass (*Juncus gerardii*), arrowgrass (*Triglochin*) or saltmeadow cordgrass (*Spartina patens*) present; also found along ditch margins or pool edges. Usually occurs in tidal areas; very rare away from coast.
Food and Feeding. No detailed information on diet; presumably small invertebrates and seeds. Forages principally on or near ground or low in vegetation.
Breeding. Season mid-May to Aug; two peaks of egg-laying, one in late May to early Jun, and other in middle to late Jul, suggest two broods. Promiscuous and non-territorial; does not form pair-bond; perhaps loosely colonial. Begins nesting one to two weeks after arrival on breeding grounds. Nest a loose, bulky cup of grasses and other marsh vegetation, lined with finer material, placed on or near ground, typically within 10 cm of ground or water's surface, suspended in emergent vegetation, usually in a site having a "roof" of dry grasses or sedges from previous season. Clutch 2–6 eggs, most commonly 3–5, modal clutch size 4 eggs, pale greenish or bluish with reddish-brown speckling throughout; replacement generally laid if initial clutch lost (often destroyed by high tides); incubation by female, period 12 days; chicks fed by female alone, nestling period 8–11 days.
Movements. Migratory. Spring migration from late Apr through early May, and autumn migration from Sept through Nov, most moving in Oct; difficult to observe and thus probably often overlooked. Presumably most, if not all, movements are carried out along Atlantic coast, but nominate race has been recorded in W Pennsylvania. Nominate race winters casually N as far as Massachusetts.
Status and Conservation. VULNERABLE. Classified as "Highest Concern" in the USA (Red WatchList priority species for conservation). Often common in appropriate habitat. Numbers decreasing; populations reduced by modification of marshland, and other coastal habitat. Estimated total population c. 250,000 individuals in first years of 21st century; recent crude estimate of density suggests that true figure more likely 50,000–100,000 individuals, and probably at lower end of this range. The species' geographical range extends in a narrow coastal band over c. 20,000 km², within which suitable habitat is greatly fragmented; effective area occupied is less than 2000 km². Main threat is the continuing loss, degradation and fragmentation of marshlands as a result of urban development; also chemical pollution of marshes, and invasive species, particularly *Phragmites* reeds (which render habitat completely unsuitable for this species). In addition, rise in sea levels caused by climatic warming potentially a serious threat. No records of brood parasitism of this species by Brown-headed Cowbird (*Molothrus ater*). Occurs within many protected areas, including Monomoy National Wildlife Refuge (Massachusetts), Blackwater National Wildlife Refuge and Fishing Bay Wildlife Management Areas (Maryland), and Cumberland Island National Seashore (Georgia).
Bibliography. Anon. (1998, 2010c), Bayard & Elphick (2011), Beadle & Rising (2002), Butchart & Stattersfield (2004), DiQuinzio *et al.* (2001, 2002), Gjerdrum *et al.* (2005, 2008), Greenlaw (1993), Greenlaw & Rising (1994), Hellmayr (1938), Hill *et al.* (2010), Hodgman *et al.* (2002), Howell & Sibley (1998), Howell & Webb (1995), Humphreys *et al.* (2007), Lebbin *et al.* (2010), Lowther (1996), McCarthy (2006), McLaren (2002), Murray (1969), Parkes (1992), Peck & James (1987), Post (1998b), Post & Greenlaw (2006), Poulson (1969), Pyle (1997), Ridgway (1901), Rising & Avise (1993), Rising & Beadle (1996), Shriver, Gibbs *et al.* (2005), Shriver, Hodgman *et al.* (2010), Shriver, Vickery *et al.* (2007), Sibley, D.A. (1996), Stattersfield & Capper (2000), Tracey & Greenlaw (2009), Woolfenden (1956), Zink & Avise (1990).

73. Le Conte's Sparrow
Ammodramus leconteii

French: Bruant de Le Conte **German**: Leconteammer **Spanish**: Chingolo de Le Conte

Taxonomy. *Emberiza leconteii* Audubon, 1844, prairies of upper Missouri River = Fort Union, North Dakota, USA.
Genus, as currently delimited, is probably polyphyletic. Molecular studies suggest that present species is in a clade with *A. maritimus*, *A. nelsoni* and *A. caudacutus*; has hybridized with *A. nelsoni*. Monotypic.
Distribution. Breeds in Canada from SC Mackenzie (in Northwest Territories), Peace R lowlands of NE British Columbia and throughout lowlands of Alberta E to C Manitoba, N & E Ontario and locally S Quebec, S in USA to NW Montana, N South Dakota, S Minnesota and N Michigan; non-breeding S USA from C Kansas, NW Arkansas, S Georgia and coastal South Carolina S to Gulf Coast (Texas E to W Florida).

Descriptive notes. 10·5–12·5 cm; 10–16·3 g. A small sparrow with short tail, rectrices spike-like, and bright ochre supercilium. Has whitish median crownstripe bordered by two dark brown lateral crownstripes, bright yellow-ochre supercilium, blackish eyestripe wedge-shaped, being narrow at eye; ear-coverts greyish-ochre, thinly edged with brown, submoustachial stripe ochre; nape greyish with chestnut stripes; mantle and upper back dark brown or blackish with buffy feather edges, rump and uppertail-coverts dark with buffy feathers edges; tail buffy brown; lesser upperwing-coverts brown, remaining wing mostly blackish-brown, feathers with pale buffy edges, broadest on median and greater coverts and tertials (by breeding season, buffy edges of fresh plumage have mostly worn off); throat white or whitish; breast and flanks buff, breast with long narrow streaks, flanks with broader blackish streaks, belly white, undertail-coverts buffy; iris dark brown; bill greyish-blue with broadly blackish culmen (non-breeding, bill brownish-horn to pinkish); legs flesh-coloured. Sexes similar in coloration. Juvenile resembles adult, but more extensively streaked on underparts, less ochre, and lacks chestnut marks on nape. Voice. Song a short insect-like "reese-reese", "z-z-z-buzz" or "tzeek-tzzz-tick". Call a sharp "chip".
Habitat. Breeds in moist to wet grasslands, sometimes mixed with cat-tail (*Typha*) and *Phragmites* reeds, or sedge (*Carex*) marshes, often interspersed with small trees or bushes. In winter found in rank tall grasses, damp weedy fields, cat-tails, and in overgrown prairies. Occurs from sea-level up to 1100 m.
Food and Feeding. Little detailed information. Diet during breeding mainly adult and larval insects, also seeds; probably feeds young principally on insects. Stomach analyses show that diet during migration principally grass seeds (e.g. *Andropogon*, *Panicum*, *Myosotis*, *Setaria*, *Sorghastrum*), as well as arthropods, including arachnid and beetles (Coleoptera). Forages principally on or near ground and low in vegetation. Occasionally in pairs or small groups outside breeding season.
Breeding. In general, has been little studied, and breeding behaviour is not well known. Season late May to mid-Aug. Monogamous. Perhaps loosely colonial. Nest a cup made from dried grasses, lined with finer grass and hair, placed on or up to 20 cm above ground, when on ground well hidden and with overhanging canopy of dead grass concealing nest from above. Clutch 4–5 eggs, whitish to pale greenish with brown to cinnamon spotting; incubation by female only, period up to 13 days; chicks fed by both parents, no information on nestling period. Nests relatively frequently



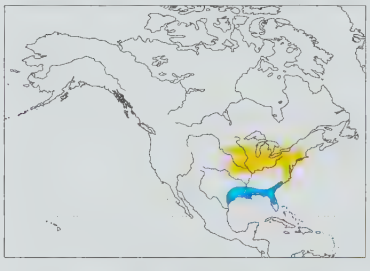
parasitized by Brown-headed Cowbird (*Molothrus ater*); success rates of host and parasite as yet unstudied.
Movements. Migratory. Difficult to observe and probably often overlooked; migration routes appear to be through E Great Plains E to Mississippi Valley. Leaves wintering areas from late Mar to early Apr, and first arrivals in S portion of breeding range by late Apr/early May, into late May in N part of breeding range. A relatively late autumn migrant, first movements S in mid-Sept and peak passage in middle to late Oct, arrival on wintering grounds in early Nov; some young migrate S still in juvenile plumage. Casual on E US coast and in N Mexico (Coahuila); vagrant in W USA as far as California.
Status and Conservation. Not globally threatened. Classed as "Declining" in the USA (Yellow WatchList priority species for conservation). Often common in appropriate habitat; most numerous in W of range. Declining. Global population recently estimated at 2,900,000 individuals, but this requires corroboration. Has suffered loss and degradation of native grasslands through extensive conversion to cropfields, overgrazing, and fire suppression; also, early mowing or haymaking reduces breeding success in hay fields. Has benefited from carefully planned burning, breeding densities in some areas reaching a peak two years after fire; in US part of range, some habitat restoration has been achieved through the Conservation Reserve Program. Occurs as a breeder or winterer in many protected areas.
Bibliography. Anon. (1998), Beadle & Rising (2002), Boulva & Browne (1965), Cooper (1984), Dove *et al.* (2001), Easterla (1962), Gilligan *et al.* (1985), Guarente (2009), Hellmayr (1938), Howell & Webb (1995), Igl & Johnson (1995, 1999), Johnson & Usyk (2009), Kaplan & Moore (1988), Lebbin *et al.* (2010), Lowther (1996), Maxwell *et al.* (1988), McCarthy (2006), McNair & Post (2000), Murray (1969), Patrikeev (2006a), Peck & James (1987), Powell & Nyari (2007), Pyle (1997), Ridgway (1901), Rising & Beadle (1996), Villard & Bracken (1989), Winter *et al.* (2005).

74. Baird's Sparrow

Ammodramus bairdii

French: Bruant de Baird **German**: Bairdammer **Spanish**: Chingolo de Baird

Taxonomy. *Emberiza bairdii* Audubon, 1844, prairies of upper Missouri = near Old Fort Union, North Dakota, USA.
Genus, as currently delimited, is probably polyphyletic. Molecular studies suggest that present species is closely related to *A. henslowii* in a clade that includes also *Melospiza*, *Passerculus* and *Xenospiza baileyi*. Monotypic.
Distribution. Breeds in SW Canada from SE Alberta, C Saskatchewan and SW Manitoba, S in N USA to NE & NC Montana (possibly to E Wyoming) and NW South Dakota, perhaps also still NW Minnesota; winters in S USA (SE Arizona, New Mexico and NC Texas) and N Mexico (NE Sonora E to W Coahuila, S to Durango and N Zacatecas).



Descriptive notes. 12–14 cm; 15–21·5 g. A medium-sized, rather short-tailed sparrow. Head is mostly ochraceous, crown heavily streaked with dark brown, a more or less distinct buffy-ochre median crownstripe tending to become wider towards nape, buff or ochre supercilium bordered below by indistinct dark spots; ear-coverts buffy or ochre, edged posteriorly with dark brown spots, thin dark brown moustachial stripe, thin dark brown malar stripe; nape ochre, boldly marked with short, thin dark streaks; mantle and back dark brown, feathers distinctly edged buff, rump and uppertail-coverts brownish with darker centres; tail dark brown, outermost feather pair with whitish on outer webs; upperwing brown, wing-coverts and scapulars edged with ochre, often slightly rusty in colour; throat pale buff; breast and flanks pale buffy ochre, thinly streaked with blackish (necklace of small dark spots), rest of underparts whitish; iris brown; bill pale flesh-coloured, darker brownish on culmen; legs pale flesh-coloured. Sexes similar. Juvenile has crown and nape buffy ochre, heavily speckled with brown, broadly edged with buffy-ochre; breast and flanks more heavily spotted than on adult. VOICE. Song a clear, loud series of ringing notes ending in melodious trill, "zhe zhe she zurrrrrrrrl". Call a whining "meeerr", sometimes repeated if agitated, also a sharp "chup", "chip" or "kee-keep".
Habitat. Breeds in ungrazed or lightly grazed grassland interspersed with scattered clumps of grass and low shrubs, such as sage (*Artemisia*) and western snowberry (*Symphoricarpos occidentalis*), with tangled matted grass on ground; in some places shows strong preference for native grasses such as wheatgrass (*Agropyron*), junegrass (*Koeleria*) and needlegrass (*Stipa*), but in other places breeds in exotic grasses a few years after their introduction. May move into an area 3–5 years after a burn; in dry years often found in dried-out ponds or depressions. In non-breeding season found mainly in bunchgrasses (*Bouteloua*, *Eragrostis*). Occurs at elevational range of 1200–2000 m.
Food and Feeding. Feeds on seeds, but also takes insects such as beetles (Coleoptera), Orthoptera, Lepidoptera larvae and flies (Diptera), and spiders (Araneae); in winter probably principally on seeds and waste grain. Forages mostly on or near ground and low in vegetation. Generally rather shy.
Breeding. Season late May to mid-Aug; usually single-brooded, sometimes two broods. Monogamous, occasionally polygynous. Nest had coarse exterior made from thicker dry grass and stems, lining includes fine grasses, rootlets, fur or moss, placed on ground in depression. Clutch 2–6 eggs, usually 4 or 5, greyish-white with rusty or chestnut spots; incubation by female, period 11–12 days; chicks fed by both parents, nestling period 8–11 days. Nests parasitized with moderate frequency by Brown-headed Cowbird (*Molothrus ater*); cowbirds known to have fledged successfully.
Movements. Migratory; movements occur through Great Plains (passage recorded through E Colorado, W & C Kansas, W Oklahoma, W Texas, perhaps E to W Missouri). Leaves wintering areas in N Mexico (Sonora) by early Mar, but some remain later in S USA (Texas); because of this species' very skulking nature, particularly during migration, timing of migration difficult to assess, but present through much of Great Plains between early Apr and mid-May; arrival on breeding grounds early May to late May depending on latitude, males from a few days to a week before females. Leaves breeding area by late Sept; migration S spans period from late Aug to late Oct, reaching Texas from early Sept and Sonora by early Oct. Casual in SW British Columbia (SW Canada) and (in USA) California, S Texas, Oklahoma, and E to Wisconsin, New York and Maryland.
Status and Conservation. Not globally threatened. Classified as "Highest Concern" in the USA (Red WatchList priority species for conservation). Locally common in appropriate habitat. Declining. Global population estimated at 1,200,000 individuals, but this requires corroboration. Apparently was formerly quite common, but has been greatly affected by habitat destruction caused mainly by agricultural expansion and overgrazing. On wintering grounds in Arizona has decreased in historic times, but difficult to assess degree of this decrease; currently found in Arizona mostly in Cochise County, in extreme SE. Main threats are the continuing loss and degradation of native grasslands through conversion to cropfields, overgrazing, and fire suppression (which leads to growth of shrubs). This species is vulnerable also to elevated levels of cowbird parasitism in habitat fragments, and reduced breeding success caused by early mowing of fields. Population in Saskatchewan (Canada) increased locally following habitat management; habitat-restoration work in progress at several National Wildlife Refuges in USA, and breeding densities in North Dakota found to reach a peak 2–4 years after controlled burns. This species occurs in several protected areas.
Bibliography. Ahlering *et al.* (2006, 2009), Anon. (1998), Beadle & Rising (2002), Cartwright *et al.* (1937), Davis (2003), Davis & Sealy (1998), Green *et al.* (2002), Hellmayr (1938), Howell & Webb (1995), Hubbard (1972a), Jones *et al.* (1998), Lebbin *et al.* (2010), Marks & Nordhagen (2005), Miller *et al.* (1957), Ridgway (1901), Rising & Beadle (1996), Russell & Monson (1998), Sutter *et al.* (1995), Voelker (2004), Winter (1999a), Zink & Avise (1990).

75. Henslow's Sparrow

Ammodramus henslowii

French: Bruant de Henslow **German**: Henslowammer **Spanish**: Chingolo de Henslow

Taxonomy. *Emberiza henslowii* Audubon, 1829, opposite Cincinnati, Kentucky, USA.
Genus, as currently delimited, is probably polyphyletic. Molecular studies suggest that present species is closely related to *A. bairdii* in a clade that includes also *Melospiza*, *Passerculus* and *Xenospiza baileyi*. Races weakly differentiated; proposed race *houstonensis* (based on a population that lived in Houston, in SE Texas), probably inseparable from nominate, is now extinct. Species sometimes treated as monotypic. Two subspecies provisionally recognized.
Subspecies and Distribution.
A. h. henslowii (Audubon, 1829) – breeds from E South Dakota E through C Wisconsin and S Canada (S Ontario) to C New York, S to C Kansas, Missouri, Arkansas, N Kentucky and C West Virginia; winters in S USA from C Texas E to South Carolina, S to Gulf Coast and N Florida.
A. h. susurrans (Brewster, 1918) – breeds from C New York E to S New Hampshire, S to E West Virginia and E North Carolina; winters along US coastal plain from South Carolina S to C Florida.

Descriptive notes. 12·1–13·3 cm; 10·6–15 g. A small sparrow, with a short tail, large bill and flat head. Nominate race has head with median crownstripe buffy olive, lateral crownstripes dark brown and streaked with buffy olive; supercilium broad and buffy olive, sometimes with greenish hue; eyestripe, moustachial stripe and malar stripe dark brown and fairly thin; nape buffy olive, streaked dark brown; mantle and upper back feathers dark brown, edged buff, lower back and rump buffy olive with brown feather centres; tail feathers blackish with rufous edges, central pair dark brown with broad rusty-brown edges; lesser upperwing-coverts rufous with olive fringes, remaining wing feathers dark brown, median and greater coverts edged rufous, tertials and sometimes secondaries edged rusty, tertials with whitish fringes; yellow at bend of wing; throat pale buff; breast and flanks darker and with thin brown streaks, belly whitish, undertail-coverts buffy; iris dark brown; culmen and most of upper mandible dark horn-grey to dusky brown, cutting edges and lower mandible flesh-coloured; legs flesh-coloured. Sexes similar in coloration. Juvenile is similar to adult, but somewhat buffier, lacks moustachial and malar stripes, has little or no streaking on breast and flanks. Race *susurrans* is darker, more saturated in colour, than nominate and has larger and deeper bill. VOICE. Song, often delivered at night, is a short, insect-like "tsi-lick" or "flee-sic"; rarely, a longer song given. Call "tsip".
Habitat. Breeds in native prairie with tall, dense grass and with matted ground cover. Often colonizes an area a few years after a burn, or occupies infrequently mowed pastures, but avoids fields with encroachment of woody plants. Breeds also in extensive grasslands covering reclaimed strip mines. In non-breeding season found in open prairies or open pine (*Pinus*) forest; most common in meadows in pine woods where broomsedge (*Andropogon virginicus*) and wiregrass (*Aristida stricta*) predominate. Sea-level to 1100 m.
Food and Feeding. In summer feeds primarily on insects, especially grasshoppers (Orthoptera) and beetles (Coleoptera); in winter mainly seeds, especially those of wiregrass. Forages principally on or near ground and low in vegetation; unobtrusive. Occasionally in small groups outside breeding season.
Breeding. Laying May–Aug; perhaps single-brooded in N of range, and in some S areas, such as Missouri, two peaks of egg-laying, suggesting species may be double-brooded. Monogamous. Cooperative breeding recorded: three adults feeding nestlings at one nest. Nest built in 4–6 days, a cup constructed from dry grass, lined with finer grasses, placed 6–8 cm above ground and sitting snugly within adjacent vegetation (not woven into it), in area with much litter such as dry grass and weedy stalks. Clutch 2–5 eggs, most commonly 4, creamy-coloured to pale greenish with reddish spotting; incubation by female, period 11–12 days; chicks fed by both parents, nestling period 9 days. Nests parasitized rarely by Brown-headed Cowbird (*Molothrus ater*).
Movements. Short-distance migrant; movements strictly nocturnal. Migration routes and timing very poorly known, as species is extremely difficult to observe. Movements N from wintering areas begin in Mar, but more move in Apr; in Tennessee recorded early Mar to late May, in Kansas mid-Apr to early May, and at Point Pelee (Ontario) largely in first two weeks of May; arrival on breeding grounds in Illinois by mid-Apr, some as early as late Mar. Often does not return to same breeding areas as those used in previous years. Many birds begin to leave breeding grounds in Sept, but true picture unclear as species becomes extremely difficult to detect once breeding over; arrival in wintering areas early to middle Oct. Accidental W to North Dakota, Colorado and New Mexico.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Classified as "Highest Concern" in the USA (Red WatchList priority species for conservation). Often common in appropriate habitat. Decreasing. Global population estimated at c. 79,000 mature individuals. Data from Breeding Bird Survey and Christmas Bird Count reveal that this species has suffered a large and significant decrease of c. 96% since 1970s; recent analysis indicated that population now stable (and may have started to increase in some regions). Greatest declines in N & E of range; now extinct or locally rare breeder in NE USA from Vermont S to Delaware. Main threats are

wetland drainage and destruction of grassland through fire suppression, conversion to agriculture or exotic plantations, combined with earlier (and more frequent) cutting of hay fields. S populations may have increased, apparently assisted by creation of undisturbed grassland habitat by the Conservation Reserve Program. Periodic burning of tall-grass prairie, on a three-year or four-year cycle benefits this species, as does occasional mowing of pastures.

Bibliography. Anon. (1998, 2010c), Aquila *et al.* (2007), Arbour & Wood (2006), Bajema & Lima (2001), Bajema *et al.* (2001), Beadle & Rising (2002), Bechtoldt & Stouffer (2005), Burhans (2002), Butchart & Stattersfield (2004), Carrie *et al.* (2002), Cully & Michaels (2000), Dimiceli *et al.* (2007), Dornak (2010), Graber (1968), Guzy *et al.* (2002), Heller & Hughes (1997), Hellmayr (1938), Herkert (2007), Herkert & Glass (1999), Herkert *et al.* (2002), Holimon *et al.* (2004), Hyde (1939), Ingold *et al.* (2009), Johnson, DiMiceli & Stouffer (2009), Johnson, DiMiceli, Stouffer & Brooks (2011), Kim (2005), Lebbin *et al.* (2010), Leftwich & Ritchison (2008), McNair (1998a), McNair & Post (2000), Monroe & Ritchison (2005), Plentovich, Holler & Hill (1998, 1999), Pranty & Scheuerell (1997), Pyle (1997), Reinking (2002), Reinking & Hendricks (1993), Reinking *et al.* (2000), Ridgway (1901), Rising & Beadle (1996), Shaffer *et al.* (2003), Silcock & Jorgensen (2007), Skipper (1998), Thatcher *et al.* (2006), Thompson & Ely (1992), Tucker & Robinson (2003), Winter (1999b), Zimmerman (1988).

76. Grasshopper Sparrow

Ammodramus savannarum

French: Bruant sauterelle **German**: Heuschreckenammer **Spanish**: Chingolo Saltamontes

Taxonomy. *Fringilla savannarum* J. F. Gmelin, 1789, Jamaica.

Genus, as currently delimited, is probably polyphyletic. Molecular studies suggest that present species is closest to two Neotropical species, *A. humeralis* and *A. aurifrons*, all in a clade that includes some of the *Aimophila* sparrows and *Arremonops*, most of which are primarily Neotropical in distribution. Geographical variation often minimal, and many races poorly differentiated. Twelve subspecies generally recognized.

Subspecies and Distribution.

A. s. perpallidus (Coues, 1872) - breeds in SW Canada (SE British Columbia E to W Ontario) and in USA discontinuously S to W California and E to Minnesota, W Oklahoma and C Texas, also extreme NW Mexico (N Baja California); non-breeding S USA (C California, S Arizona, C Oklahoma and Gulf Coast) S through Mexico and Guatemala to El Salvador.

A. s. pratensis (Vieillot, 1818) – breeds E of Great Plains from Wisconsin E through Michigan to SE Canada (SE Ontario, S Quebec and S New Brunswick), S to E Oklahoma, NE Texas, Arkansas, North Carolina and SE Virginia; non-breeding from S limits of breeding range S to Bahamas, Cuba, E & S Mexico, Belize and Guatemala.

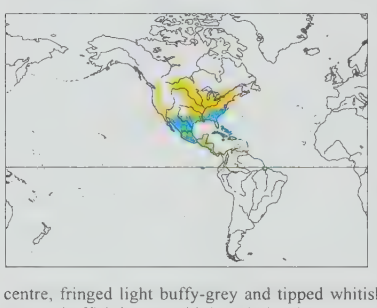
A. s. ammolegus Oberholser, 1942 – breeds in S Arizona and adjacent NW Mexico (N Sonora); non-breeding also in W Mexico (S to Oaxaca) and Guatemala.

A. s. floridanus (Mearns, 1902) – C Florida (Kissimee Prairie).

A. s. bimaculatus Swainson, 1827 – C & S Mexico (at least Zacatecas, México, S Veracruz, possibly also Oaxaca), Guatemala, Nicaragua and Costa Rica.

A. s. cracens (Bangs & Peck, 1908) – N & E Guatemala (Petén and Izabál), Belize, E Honduras and NE Nicaragua.

A. s. beatriceae Olson, 1980 – C Panama (Coclé Province).



A. s. savannarum (J. F. Gmelin, 1789) – Jamaica.

A. s. intricatus E. J. O. Hartert, 1907 – Hispaniola.

A. s. borinquensis J. L. Peters, 1917 – Puerto Rico.

A. s. caribaeus (E. J. O. Hartert, 1902) – Netherlands Antilles (Curaçao and Bonaire).

A. s. caucae Chapman, 1912 – S Colombia (upper Cauca Valley) and NW Ecuador.

Descriptive notes. 12–12·5 cm; 13·4–28·4 g. A small to medium-sized, chunky sparrow with short tail and large bill. Nominate race has head with dark brown lateral crownstripes, pale buffy median crownstripe, supercilium buffish with golden patch anteriorly, lores and ear-coverts pale buffy yellow, thin dark postocular stripe; nape buffish-grey with blackish streaks, side of neck buffy; upperparts greyish, streaked blackish, with centres of feathers light rufous, rump and uppertail-coverts mottled rufous; tail feathers brown, edged pale buff; upperwing brown, feathers edged pale brown, median coverts broadly blackish-brown on centre, fringed light buffy-grey and tipped whitish-buff, with short brown apical streak, greater coverts buffish-brown with broad blackish centres, each divided by fulvous brown apical triangle and with narrow greyish-buff margin, becoming whitish-buff near tip, tertials largely blackish on inner web and proximally on outer web, becoming brownish near tip, especially on inner web, rest of outer web brown becoming blackish near shaft and pale buff on edge towards feather tip; throat whitish, underparts whitish with pale buffy wash; iris dark brown; bill fleshy-horn to grey, culmen broadly darker greyish; legs pinkish. Sexes alike in coloration. Juvenile has crown, nape and upperparts dark brown, feathers edged pale buff or rusty brown, median crownstripe indistinct, underparts finely streaked with brown spots, streaks strongest on breast, upper mandible dark. Races differ mainly in size, bill size and general coloration: *borinquensis* is smaller than nominate, and has brighter median crownstripe; *intricatus* is like previous, but browner on head; *caribaeus* is paler than previous two and nominate; *pratensis* is rather small, with heavy bill and dark mantle colour, darker than nominate, streaks on nape rufous (not blackish); *perpallidus* is like last, but somewhat paler; *ammolegus* has distal portion of feathers of back and wing with rufous centres, breast to flanks also more richly coloured; *floridanus* has dark back; *cracens* is very dark above, with buffy underparts; *bimaculatus* is rather richly coloured, but paler than previous; *beatriceae* has paler grey back, is paler than preceding two races; *caucae* is similar to last, but brownish-black on nape, perhaps even paler below. Voice. Song, often at night, variable, characteristically 2–3 high notes followed by high trill, "chip chip scheeeeeeeee" or "c chit zhuzeeeeee"; also gives more complex excited song at times. Call a weak "tillic".

Habitat. Tall dense grassland, also rice fields. In arid W Great Plains, tends to be found in areas with relatively lush grass with weeds. In E North America often in drier habitats than those preferred by *Passerculus sandwichensis*, and often at lower elevations than *Passerculus sandwichensis* (although overlap in ranges and ecology); in Florida, generally in wiregrass (*Aristida stricta*) and palmetto (*Serenoa repens*). In winter, in E, occurs in grass-dominated areas with smooth crabgrass (*Digitaria ischaemum*) and broomsedge (*Andropogon virginicus*); in C Florida in native prairie; in Mexico and Belize occasionally in grazed pastures. Lowlands to 2500 m.

Food and Feeding. Diet small arthropods and seeds. In summer mainly insects, especially grasshoppers (Orthoptera), but also beetles (Coleoptera) and larval butterflies and moths (Lepidoptera), also some spiders (Araneae); also variety of seeds, such as those of panicgrass (*Panicum*) and sedges (Cyperaceae). Forages principally on or near ground and low in vegetation.

Breeding. Season varies depending on region, in Great Plains mid-May to Jul/mid-Aug and often two or more broods raised, farther S up to four broods per season; in Florida and Jamaica may be bi-modal, breeding often following fires, and up to four broods; little information on more tropical populations. Monogamous; cases of polygyny recently documented. Sometimes breeds co-operatively, with helpers, the latter juveniles from earlier brood(s). Nest constructed from dry grasses and stalks, lined with finer grasses, sedges or hair, placed on ground, often with a concealing dome of overhanging grasses. Clutch 3–6 eggs, usually 4–5, creamy white with greyish or reddish spots, which concentrated towards wider end; incubation by female, period 11–13 days; chicks fed by both parents and by any helpers present, nestling period 8–9 days. Brood parasitism by Brown-headed Cowbird (*Molothrus ater*) generally infrequent.

Movements. N populations (especially races *pratensis* and *perpallidus*) migratory, *ammolegus* a partial migrant; other populations resident, but may move locally depending on rainfall and grass heights. In spring, a relatively late migrant; in California arrives in C part of state by late Feb to early Mar, although in some years not until late May or Jun, and in E arrives in S of breeding range by middle to late Apr; farther N reaches N US states and S Canada in early or middle May, Massachusetts to Maine in late May; males arrive on breeding grounds 3–5 days before females. Autumn migration difficult to detect owing to the species' secretive nature; leaves N breeding grounds from Aug, mainly in Sept; migrants observed in Florida late Sept to Dec, and tower kills in C Florida show peak numbers between late Oct and late Nov. In Canadian Maritimes autumn vagrants tend to occur in Oct; off-course individuals in Bermuda from late Sept.

Status and Conservation. Not globally threatened. Race *floridanus* federally listed as Endangered; listed as a California Bird Species of Special Concern. Often common in appropriate habitat. In many parts of range local in distribution. Many populations have decreased in size in recent years as a consequence of habitat loss, the result largely of agricultural conversion and urbanization. For example, in California this species is placed in the second highest order of priority for conservation, this due to conversion of grasslands throughout the state.

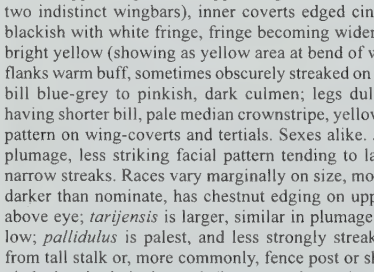
77. Grassland Sparrow

Ammodramus humeralis

French: Bruant des savanes **German**: Wachtelammer **Spanish**: Chingolo Pajonalero

Taxonomy. *Tanagra humeralis* Bosc, 1792, Cayenne, French Guiana.

Formerly placed with *A. aurifrons* in a separate genus, *Myospiza*. The two sometimes considered to form a superspecies, but ranges overlap sufficiently to make such treatment implausible. Genetic studies indicate that the two are closely related to *A. savannarum*, which is, in turn, distant from other six species currently included in genus; these last should perhaps be reassigned to a different genus. Four subspecies recognized.



Subspecies and Distribution.

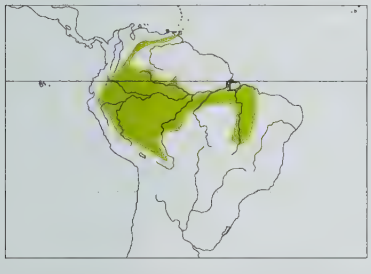
A. h. pallidulus (Wetmore, 1949) – Guajira Peninsula of N Colombia and NW Venezuela.

A. h. humeralis (Bosc, 1792) – Colombia and Venezuela (except Guajira Peninsula), and the Guianas E to E Brazil (S to Paraná).

A. h. xanthornus Gould, 1839 – extreme SE Peru (Pampas del Heath) and NE Bolivia E through SC Brazil to Paraguay and Uruguay and S to C Argentina.

A. h. tarijensis (J. Bond & Meyer de Schauensee, 1939) – SE Bolivia (Santa Cruz, Tarija and Chuquisaca).

Descriptive notes. 13 cm; 13–19 g. A short-tailed and large-headed sparrow with medium-sized bill, relatively long legs and large feet, and short wing, primaries entirely hidden by tertials. Nominate race has distinctive head pattern, having brown crown with neat and well-defined white central crownstripe, greyish-brown face with pale lores, noticeable yellow patch in supraloral area continuing as pale grey supercilium; dark brown postocular stripe broadens as it reaches side of neck; nape and hindneck grey with narrow rusty streaking, back grey and warm brown with darker streaking, rump unstreaked warm brown; tail brown; upperwing brown, upperwing-coverts with broad blackish centres and pale tips (creating two indistinct wingbars), inner coverts edged cinnamon, outer ones grey or grey-brown, tertials blackish with white fringe, fringe becoming wider and cinnamon towards bases; marginal coverts bright yellow (showing as yellow area at bend of wing on perched bird); throat whitish; breast and flanks warm buff, sometimes obscurely streaked on rear flanks, rest of underparts off-white; iris dark; bill blue-grey to pinkish, dark culmen; legs dull pinkish. Distinguished from *A. aurifrons* by having shorter bill, pale median crownstripe, yellow on face restricted to supraloral area, and bolder pattern on wing-coverts and tertials. Sexes alike. Juvenile is similar to adult, but paler and duller plumage, less striking facial pattern tending to lack yellow in loral area, and has breastband of narrow streaks. Races vary marginally on size, more distinctly in plumage darkness: *xanthornus* is darker than nominate, has chestnut edging on upperparts, and deeper and more extensive yellow above eye; *tarijensis* is larger, similar in plumage to previous, but browner above and buffier below; *pallidulus* is palest, and less strongly streaked on upperparts than nominate. Voice. Song, from tall stalk or, more commonly, fence post or shrub, plaintive, musical and sweet, though high-pitched and relatively weak (but on cool mornings with little air movement, carries for surprising distance), begins with sweeter longer note (sometimes 2), then short and buzzy notes, and ends in light and longer trill usually falling slightly in pitch, "sweep–siip tzzt tk treeeeeeeee"; individual



variation, and middle elements quite buzzy in some variants, but pattern similar through range. Call a high-pitched yet rather liquid "tiip".
Habitat. Variety of grassland, from tall grassland to savanna, *campos* and *cerrado* of Brazil, as well as drier *pampas* in S Brazil, Uruguay and Argentina; moist grassland, in *pampas* also those moist enough to have sedges (*Cyperus articulatus*). Found also in pastures and other agricultural areas with grassy field edge. Absent where overgrazed and grass is too short. To 1300 m.
Food and Feeding. Diet seeds and insects, latter particularly during breeding season. Forages exclusively on ground. Adults specialize on grass seeds, and will use feet to pull down taller grasses, enabling them to feed on them while on ground.
Breeding. Season Apr–Aug in N and Sept–Feb in S. Cup-shaped nest placed on ground, with runway leading to it through grass; sometimes grass grows over runway, creating loosely covered tunnel. Clutch 3–4 eggs, pale whitish. No other information.
Movements. Resident in much of range; possibly short-distance migrant in C Argentina.
Status and Conservation. Not globally threatened. Fairly common throughout most of extensive range. Preference for a variety of grassy and open habitats makes this a low-sensitivity species, and forest clearance likely increasing available habitat for it. Occurs in several protected areas.
Bibliography. Armani (1985), Byers, Curson & Olsson (1995), Carson & Spicer (2003), Costa & Costa (2003), Cruz & Andrews (1989), Graham *et al.* (1980), Klicka & Spellman (2007), Lill (1974), Marcondes-Machado (1988d), de la Peña (1975, 1987), Restall *et al.* (2006), Ridgely & Tudor (1989), Storer (1989b).

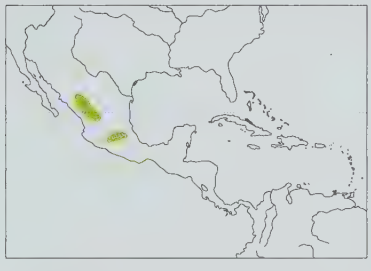
78. **Yellow-browed Sparrow**

Ammodramus aurifrons

French: Bruant à front d'or **German**: Gelbwangenammer **Spanish**: Chingolo Cejigualdo

Taxonomy. *Tanagra aurifrons* Spix, 1825, "in provincia Bahia"; error = Fonte Bõa, Rio Solimões, Brazil. Formerly placed with *A. humeralis* in a separate genus, *Myospiza*. The two sometimes considered to form a superspecies, but ranges overlap sufficiently to make such treatment implausible. Genetic studies indicate that the two are closely related to *A. savannarum*, which is, in turn, distant from other six species currently included in genus; these last should perhaps be reassigned to a different genus. Four subspecies recognized.
Subspecies and Distribution.
A. a. apurensis (Phelps, Sr & Gilliard, 1941) – NE Colombia E through *llanos* of W Venezuela to Orinoco Delta.
A. a. cherriei (Chapman, 1914) – EC Colombia (in *llanos* of Meta).
A. a. tenebrosus (J. T. Zimmer & Phelps, Sr, 1949) – SW Venezuela (SW Amazonas), SE Colombia (Guainía and E Vaupés) and adjacent W Brazil.
A. a. aurifrons (Spix, 1825) – SE Colombia (SE of Andes) S through E Ecuador and E Peru to NE Bolivia, and E through Amazonian Brazil.

Descriptive notes. 13 cm; 14·5–19 g. A short-tailed and long-legged sparrow with relatively long and stout bill and short wing, primaries entirely hidden by tertials. Nominate race has grey head with fine darker streaking on crown, prominent bright yellow supercilium extending half-way back on head and continuing pale grey on rear head, largely greyish face with yellow wash on lores, yellow often extending below eye and to base of malar region; upperparts grey with darker streaking, rump unstreaked grey-brown; tail brown; lesser upperwing-coverts dark brown with broad olive-yellow fringes, median coverts similar but fringed buffish, often paler at tip, forming rather weak wingbar, rest of upperwing feathers dark brown with brown to grey fringes, marginal coverts bright yellow (showing as yellow area at bend of wing on perched bird); throat whitish, narrow brownish moustachial line; breast and flanks grey, rest of underparts off-white; iris dark; bill dark above, blue-grey below; legs greyish-flesh to dull pink. Distinguished from *A. humeralis* by longer bill, extensive yellow on face, lack of median crownstripe, and less distinct pattern on coverts and tertials. Sexes alike. Juvenile is similar to adult, but paler and duller plumage, lacking much yellow on face, and has breastband of narrow streaks. Races differ in darkness of plumage, also in extent of yellow on face: *cherrieri* has less yellow on face than nominate; *apurensis* is like previous, but has blacker and wider streaking on upperparts, and brighter white throat contrasting with buff of breast; *tenebrosus* is darkest, has orange wash on area above lores, dark grey flanks. Voice. Song, often given in heat of midday, a high-pitched, insect-like, nasal double trill, "tzeeee-tzneeeeee", often preceded by very soft "tk" note (audible only at very close quarters). Call a high-pitched "tip".
Habitat. Lowland tropical grassland and open sites, although found commonly to 1000 m in E Ecuador, and exceptionally to 2500 m. Essentially will accept any open habitat, including short grass, taller grass, pastures, open areas adjacent to villages, roadside grassy spots, and all kinds of open and degraded habitats, including empty lots in cities. Very adaptable.
Food and Feeding. Seeds and insects; nestling diet arthropods. Forages exclusively on ground, specializing on grass seeds. Often forages in the open, and, unlike *A. humeralis*, not hidden in grass.
Breeding. Season May–Oct in Venezuela and Feb–Sept in Colombia. Cup-shaped nest of dried grass, lined with finer material, placed on ground; clutch 2–3 eggs, whitish. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Fairly common throughout most of extensive range. Very adaptable, this species' preference for variety of grassy and open habitats makes it one of low sensitivity, and forest clearance is increasing available habitat for it; is quickly gaining habitat as Amazonian forest being cleared, and more settlements and agricultural areas established. Occurs in several protected areas.
Bibliography. Armani (1985), Byers, Curson & Olsson (1995), Carson & Spicer (2003), Cruz & Andrews (1989), Hilty (2003), Klicka & Spellman (2007), Restall *et al.* (2006), Ridgely & Tudor (1989).



Genus *XENOSPIZA* Bangs, 1931

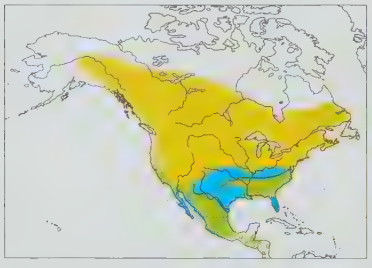
79. **Sierra Madre Sparrow**

Xenospiza baileyi

French: Bruant des sierras **German**: Sierraammer **Spanish**: Chingolo Serrano
Other common names: Bailey's Sparrow

Taxonomy. *Xenospiza baileyi* Bangs, 1931, Bolaños, Jalisco, Mexico.
Sometimes suggested as being close to *Ammodramus*, and genus sometimes subsumed in latter; song and limited molecular work, however, suggest close affinity with *Melospiza*, and may be better placed within that genus. Monotypic.
Distribution. C Mexico, where now restricted to two isolated localities: Distrito Federal (centred around La Cima and Milpa Alta, near Mexico City); and S Durango (Ejido Ojo de Agua–El Cazador).

Descriptive notes. 14–15·2 cm; 15·8–19 g. Medium-sized sparrow with very short wings. Plumage is brownish above, washed with rufous and streaked with dark brown, crown with indistinct pale median crownstripe, nape indistinctly streaked brown; supercilium grey, contrasting dark ear-coverts, with dark eyestripe, whitish submoustachial stripe often tinged buffy near side of neck, blackish malar stripe; tail dark brown, feathers edges pale greyish-rufous; upperwing dark brown, lesser coverts rufous, median and greater coverts with broad rufous edges and buffish tips, flight-feathers thinly edged buff, tertials broadly edged rufous and with narrow white fringes; bend of wing distinctly yellowish; throat and underparts whitish, breast and flanks washed buffy and with dark brown streaks, streaks sometimes coalescing into spot on central breast; iris dark; bill grey; legs yellowish-flesh to pink, often darker and greyer on feet. Sexes similar. Juvenile is duller than adult, with supercilium, throat and underparts washed yellowish-buff, lacks yellow at bend of wing. Voice. Song often begins with 2, 3 or as many as 4 or 5 rapid notes, these followed (as in song of *Passerculus sandwichensis*) by variable series of notes, 7–12 in number, expressed as "tzee", "zhip" or a scratchy "jeep", or "chi-chi-chi-chi-chi zzzzzzzr si-ch hu"; may be on a variable or ascending scale. Call a nasal "nyeu".
Habitat. Pine (*Pinus*) savanna at 2285–3050 m, mostly above 2800 m. Found in medium and tall bunchgrass meadows (*zacatón*) with the grasses *Muhlenbergia affinis*, *Muhlenbergia macroura*, *Festuca amplissima* and *Stipa ichu* interspersed with stands of pines, mainly Montezuma pine (*Pinus montezumae*), Hartweg's pine (*Pinus hartwegii*) and teocote (*Pinus teocote*); also in open pine–oak (*Pinus–Quercus rugosa*) woodland. In Durango occurs in dry marshes in tall grass, but not necessarily found near marshy areas. Bushes absent in habitat.
Food and Feeding. Observed to feed on moths and caterpillars (Lepidoptera), flying ants (Formicidae), earthworms (Lumbricidae), and grass seed. Stomach of one bird contained remains of a small beetle (Coleoptera) and a spider (Araneae). Forages mostly on and near ground within clumps of grass. Generally very secretive.
Breeding. Eggs and young found in Jun and Jul, nest with young in Aug, and juveniles recorded Aug and Sept. Nest built by female, taking 2–4 days, consists of outer shell of coarse grasses, lined with fine grasses and rootlets, and small amounts of horsehair, built c. 0·3 m above ground in middle of clump of bunchgrass or near ground between clumps of grasses. Clutch 3 eggs, blue-green with fine spots of burnt umber or blackish; incubation by female, period 15–16 days; chicks brooded by female, fed by both sexes, nestling period 9–12 days. Of eleven nests in one study, 36% succeeded in fledging young.
Movements. Apparently sedentary; possible short-distance post-breeding dispersal.
Status and Conservation. ENDANGERED. Restricted-range species: present in Sierra Madre Occidental and trans-Mexican range EBA. Locally common; has very small range, within which populations appear to be in rapid decline. Global population put at 2500–9999 mature individuals, great majority at a single site. According to recent survey, species now survives at only two locations: one in Distrito Federal (centred around La Cima and Milpa Alta, near Mexico City), where population in 1997 estimated at 5380–6150 adults; the other in S Durango (Ejido Ojo de Agua–El Cazador), where at least three breeding pairs concentrated in area of 0·5 ha within an 80-ha marsh and total population probably no more than 50 individuals. Density of 2·9 territories/ha recorded at La Cima. A report of this species at Los Dinamos (Distrito Federal) in 1993 referred to a misidentified juvenile of *Melospiza melodia*. Formerly occurred at four sites in S Durango and N Jalisco and at several localities around Distrito Federal–Morelos border. Had not been recorded in Durango since 1951 until rediscovered there in 2004. Overgrazing and fires remain a major threat; uncontrolled burning of bunchgrass meadows to create new pasture for sheep and cattle has destroyed much of the species' preferred habitat. Much of the tillable habitat in La Cima area has already been ploughed, and most of the habitat in Durango has been lost to logging and cultivation. At the main site, area of suitable habitat has decreased by c. 50% in ten years since end of 20th century. In addition, mycotoxins (from contaminated grain) found to have caused some mortality, and nesting failure very common owing to heavy predation, which may be exacerbated by habitat fragmentation. Conservation measures require urgent monitoring of remaining populations, and survey of suitable habitat in Durango, as well as effective protection of surviving habitat fragments; also encouragement for local inhabitants to develop appropriate grassland-management strategies and to ensure prevention of potential poisoning by micotoxins.
Bibliography. Anon. (2010c), Armani (1985), Butchart & Stattersfield (2004), Cabrera-Garcia *et al.* (2006), Collar *et al.* (1992), Dickerman *et al.* (1967), Howell & Webb (1995), Klicka & Spellman (2007), Miller *et al.* (1957), Oliveras de Ita & Gómez de Silva Garza (2002, 2007), Oliveras de Ita & Rojas-Soto (2006), Oliveras de Ita *et al.* (2001), Pitelka (1947), Rojas-Soto *et al.* (2008), Stattersfield & Capper (2000).



Genus *SPIZELLA* Bonaparte, 1832

80. Chipping Sparrow

Spizella passerina

French: Bruant familier **German**: Schwirrammer **Spanish**: Chingolo Cejiblanco

Taxonomy. *Fringilla passerina* Bechstein, 1798, Quebec City, Canada.
Probably closely related to *S. pallida* and *S. breweri*, and individuals of the three in first-winter plumage difficult to differentiate. Geographical variation rather minimal, and in North America clinal, with slight increase in darkness from W to E; also substantial individual variation within populations. Proposed races *stridula* (described from Pasadena, California) and *boreophila* (from Fort Simpson, Mackenzie, in Canada) are considered synonyms of *arizonae*, *comparanda* (from SE Nayarit, in W Mexico) is included within *atremaea*, *repetens* (from R Molino in S Oaxaca, in Mexico) is subsumed in *mexicana*, and *cicada* (from near Chalatenango, in NW El Salvador) is synonymized with *pinetorum*. Five subspecies recognized.
Subspecies and Distribution.
S. p. arizonae Coues, 1872 – breeds in E Alaska, W & C Canada (from W Yukon and C Mackenzie E to N Saskatchewan, N Manitoba and W Ontario) and W USA (E to W & C Texas), S to Mexico (N Baja California, NW Sonora, SW Chihuahua, Durango and Coahuila); non-breeding from SW USA (C California, S Nevada, C & SE Arizona, C New Mexico and C Texas) S to S Baja California and highlands of Mexico (S to Oaxaca).
S. p. passerina (Bechstein, 1798) – breeds in N Minnesota, N Michigan and SE Canada (C Ontario and S Quebec E to SW Newfoundland) S in USA to S Oklahoma, SE Texas, C Louisiana, S Mississippi, NW Florida, C Georgia and SE South Carolina; non-breeding from Oklahoma and Arkansas E to Virginia and Maryland S to S Florida, Gulf Coast and NE Mexico (Nuevo León and Tamaulipas).
S. p. atremaea R. T. Moore, 1937 – W Mexico in Sierra Madre Occidental from S Chihuahua and S Durango E to C Nuevo León and S to Aguascalientes and NE Jalisco.
S. p. mexicana Nelson, 1899 – highlands of C & S Mexico from Nayarit, NC Jalisco, Guanajuato, San Luis Potosí, Hidalgo and E Veracruz S to Chiapas, and NW Guatemala.
S. p. pinetorum Salvin, 1863 – NE Guatemala (E Petén), Belize, Honduras, N El Salvador and NE Nicaragua.

Descriptive notes. 12–14 cm; 10·3–15·5 g. A small, slim sparrow with long, notched tail. Nominate race breeding has forehead black, usually small whitish medial spot above bill, bright rusty cap, greyish-white supercilium and black eyestripe; nape and side of head grey, very thin dark moustachial line, broad white submoustachial stripe, thin dark malar line; upperparts rusty brown with dark brown streaking, rump grey; tail brown; upperwing dark brown, feathers edged rusty, median and greater upperwing-coverts rusty, tipped white or light beige (forming one or two wingbars); throat whitish; breast and flanks grey to greyish-brown, belly dull white; iris black; bill black; legs fleshyy-pink to light brown, often duller on feet. Non-breeding plumage is like breeding but duller, with cap dull chestnut and (especially late in season) finely streaked dark brown or black, supercilium tinged brownish-yellow, rump pale brown with fine dark streaks, becoming grey, wing edgings browner; bill brownish, lower mandible flesh-coloured. Sexes similar in coloration. Juvenile resembles non-breeding adult, but a little duller, and with face, breast and flanks heavily streaked blackish. Race *arizonae* is larger and paler than nominate; *atremaea* is darker and brighter than previous, and has wider streaking above; *mexicana* is larger and darker than nominate, with rustier crown; *pinetorum* is darkest and brightest race. Voice. Song a thin, dry rattle on one pitch. Call a thin, clear "tseep" or dry "chip".
Habitat. Breeds in dry open woodland with grassy understorey, orchards, parks and golf courses; also in mixed woodland. In SW USA (California) occupies wide variety of habitats, including coniferous forest at high elevations, and orchards in humid coastal belt, and at least occasionally in Channel Is. In S Mexico (Oaxaca) breeds in arid pine–oak (*Pinus–Quercus*) woodland, and in Central America in open pine woodland. In winter in various kinds of open woodland, shrubland, brush, and arid subtropical scrub. Sea-level to at least 3500 m.
Food and Feeding. Consumes seeds throughout year; insects form bulk of diet during breeding season. Seeds of dandelion (*Taraxacum officinale*) an important spring food, but also eat seeds of black bindweed (*Fallopia convolvulus*), sweet clovers (*Melilotus*), chickweed (*Stellaria media*), lamb's quarter (*Chenopodium album*), oats (*Avena*), and of many other species. Invertebrate food principally insects, e.g. Lepidoptera, beetles (Coleoptera), Orthoptera and others; sometimes takes spiders (Araneae). Forages principally on or near ground and low in vegetation, often near edges of fields and meadows. Outside breeding season usually in small flocks.
Breeding. Season Mar–Aug, from Mar (Jun in Morelos, in Mexico) in S, but from mid-May and Jun in Oaxaca (S Mexico); commonly double-brooded, sometimes three broods in S of range. Monogamous; occasional polygyny recorded. Sometimes breeds co-operatively, with helpers. Males of migratory populations begin to sing and defend territory very soon after arrival in spring. Nest constructed by female alone, within two weeks of her arrival, a cup of dried grasses and rootlets, lined with finer grass and usually hair, particularly horsehair, placed usually above ground and normally below 6 m in bush or tree, commonly a conifer, often in open grassy area; often young, short and thick conifer chosen (up to 90% of nests are in young conifers). Clutch 2–8 eggs, usually 4, generally pale blue with sparse dark brown to purplish markings; incubation by female, period 10–12 days; chicks fed by both parents, largely by male in early days, nestling period 9–12. Nests commonly parasitized by Brown-headed Cowbird (*Molothrus ater*), often resulting in abandonment of nest. Brood parasitism causes severe reduction in productivity, but effects vary depending on locality, and populations farther N only very rarely parasitized.
Movements. N races migratory; resident in S. Begins to leave wintering grounds in S USA (Florida and Texas) in late Feb; moves through Oklahoma from late Mar to early Apr, late Apr in Minnesota and Wisconsin, and arrival in Canada (S Alberta and N Ontario) by mid-May. Arrival in more S breeding areas, such as Texas, as early as Mar. Coastal migrants along Atlantic earlier than in areas farther inland; passage along W coast in Oregon during early Apr to mid-Apr W of Cascades, and late Apr to early May E of Cascades. Males arrive at breeding areas 1–2 weeks before females. Leaves breeding grounds as early as Jul in some areas, particularly interior W; Rocky Mts populations begin S-bound movement mid-Jul (as they head to moulting grounds in Great Plains), and movements out of breeding areas farther E peak by early Aug to mid-Sept; early arrivals in wintering areas in Texas and Florida by mid-Sept, and peak in arrival during early Nov.
Status and Conservation. Not globally threatened. Often common or very common in appropriate habitat. Widespread within its large range. Relatively tame, and easy to observe.
Bibliography. Albrecht & Oring (1995), Anon. (1998), Beadle & Rising (2002), Binford (1989), Bojfror (1959), Button (1937), Dickey & van Rossem (1938), Dunning (2008), Gilligan *et al.* (1994), Grinnell (1915), Hellmayr (1938), Howell & Webb (1995), Hubbard (1972a), Hubbard & Crossin (1974), Liu Wanchun & Kroodsma (2007), Marshall (1957), Middleton (1998), Middleton & Prescott (1989), Miller *et al.* (1957), Moldenhauer & Taylor (1973), Monroe (1968), Phillips *et al.* (1964), Pyle (1997), Reynolds & Knapton (1984), Rising & Beadle (1996), Rowley (1962), Russell & Monson (1998), Salvadori (1999), Scott (1988), Simmons & Sloan (1974), Sloan &

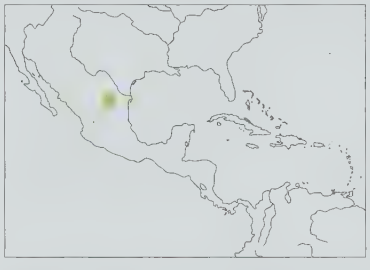
81. Field Sparrow

Spizella pusilla

French: Bruant des champs **German**: Klapperammer **Spanish**: Chingolo Campestre

Taxonomy. *Fringilla pusilla* A. Wilson, 1810, Philadelphia, Pennsylvania, USA.
Sometimes considered sister to *S. wortheni*; has been considered conspecific, but more closely resembles *S. atrogularis* in song and ecology, as well as bill colour. Races intergrade broadly in Great Plains; intermediate populations have been described as separate races, *perissura* (described from Valentine, Nebraska) and *vernonia* (Japonica, Texas), but great variability of these intergrading populations makes taxonomic separation both inappropriate and unhelpful; both herein included within *arenacea*. Two subspecies recognized.
Subspecies and Distribution.
S. p. arenacea Chadbourne, 1886 – breeds in C USA from SE Montana and North Dakota S through Great Plains to NE Colorado, W Oklahoma and C Texas; non-breeding from Kansas, C Oklahoma, N Arkansas and NW Mississippi S to NE Mexico (to N Coahuila, C Nuevo León and Tamaulipas).
S. p. pusilla (A. Wilson, 1810) – breeds in SE Canada (S Manitoba, S Ontario and S Quebec) and E USA from C Minnesota and C Michigan E to S Maine, S to E Texas, SE Louisiana, S Mississippi, SE Alabama and SW Georgia, rarely to NC Florida; non-breeding from E Kansas, C Missouri, C Ohio, N West Virginia, Maryland and S Massachusetts S to S Texas, Gulf Coast and C Florida.



Descriptive notes. 13·5–14·5 cm; 11–15·7 g. A small, slim sparrow with long, notched tail. Nominate race has rusty-pink crown with faint grey median crownstripe; side of head grey, thin white eyering, rusty postocular stripe; nape rusty; upperparts rusty with darker brown streaks, lower back to uppertail-coverts plain grey-brown or slightly streaked light brown; tail dark brown, feathers with narrow grey edges; upperwing mainly dark brown, lesser coverts mostly grey, median coverts blackish-brown with broad light buff to whitish tips, greater coverts and tertials blackish-brown with rusty to buffy edges (usually rustier on tertials) and paler tips (most notable on outer webs of greater coverts, forming a second wingbar); throat and underparts grey, tawny wash on breast and flanks; iris dark brown; bill pink; legs pale brown to pinkish-yellow. Sexes similar. Juvenile is similar to adult, but without rusty colours, crown dull grey to brown, and breast and flanks with light dusky streaks. Race *arenacea* is paler than nominate, also slightly larger, with postocular stripe less prominent. VOICE. Song, sometimes at night, a series of 2 or more clear, plaintive, run-on whistles that accelerate and ascend into a trill, "swee-swee-swee-swee-wee-wee-wiwiwi". Call "tsip", "zweep" or sharp "chip".
Habitat. Breeds in oldfields, and occasionally new plantations (Christmas-tree farms), in E parts of range often with broomsedge (*Andropogon virginicus*), crabgrass (*Digitaria*) and horseweed (*Leptilion*) and other grasses; also in shrubby woodland edges, fencerows, and brush borders of streams. Occurs up to 3500 m.
Food and Feeding. Diet includes seeds of broomsedge, horseweed, and crabgrass and other grasses; in summer insects comprise more than 50% of diet. Arthropods commonly eaten include cicadas (Cicadidae), spiders (Araneae), Orthoptera (commonly katydids), Lepidoptera larvae and adults, and flies (Diptera). Forages principally on or near ground and low in vegetation. Often in pairs or small groups outside breeding season.
Breeding. Season late Apr/early May to early Aug, in South Dakota late May through Aug; may rear several broods in a season. Usually monogamous; 2% of males in Pennsylvania polygynous. Female chooses nest-site and builds nest, often accompanied by male during building stage, nest a cup made from dry grasses and twigs, lined with finer grasses, rootlets and hair, placed on or near ground in grass clump or near base of shrub; later nests may be placed low in crotch of tree or shrub, in black raspberry (*Rubus allegheniensis*), prairie crab apple (*Malus ioensis*), red cedar (*Juniperus virginiana*), sprouting elm (*Ulmus*) or similar; nest sometimes reused for later broods. Clutch 3–5 eggs, most commonly 4, cream-coloured to pale bluish and spotted brownish or reddish throughout, but spots concentrated at wide end; incubation by female, period 10–12 days; chicks fed by both parents, nestling period 7–9 days. Nests commonly parasitized by Brown-headed Cowbird (*Molothrus ater*); often deserts parasitized nests and is a poor host, seldom raising cowbird young successfully.
Movements. Partially migratory; individuals breeding N of Massachusetts, N Kansas, and many in Ohio migrate into S USA. Routes not well known, movement likely on a generally broad front with some concentration along major river valleys. Migration has been characterized as slow and leisurely, with long stopovers. Movement out of Tennessee as early as late Feb, peak in early Mar, arriving in South Dakota, S Michigan and Wisconsin as early as mid-Mar, Nebraska mostly late Apr; overall, most of spring migration takes place during mid-Apr to early May. Males arrive in breeding areas 10–20 days before females. Begins to leave breeding grounds in Sept; mostly gone from Wisconsin by end Oct, from South Dakota and Nebraska mid-Nov; a few winter records for Nebraska, and one winter record from Manitoba. Casual in E Canada in Newfoundland, Nova Scotia, New Brunswick and SE Quebec (including Magdalen Is), and in Bermuda. Vagrant W in USA to Wyoming, California, Arizona and C New Mexico.
Status and Conservation. Not globally threatened. Often common or very common in appropriate habitat. Rare as a breeder in S Manitoba (Canada). Has benefited from clearance of forest. In Midwest numbers certainly increased after virgin forests cut; in Ohio became a common summer resident by late 19th century.

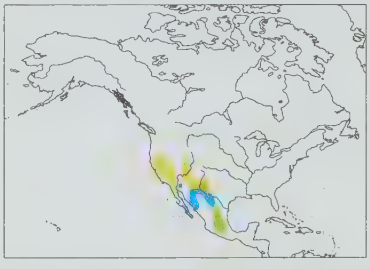
82. Worthen's Sparrow

Spizella wortheni

French: Bruant de Worthen **German**: Mexikoammer **Spanish**: Chingolo de Worthen

Taxonomy. *Spizella wortheni* Ridgway, 1884, Silver City, New Mexico, USA.
Sometimes considered sister to *S. pusilla*; has been considered conspecific, but *S. pusilla* appears closer to *S. atrogularis*. Recently published molecular data indicate that present species is sister to *S. breweri*, suggesting that plumage similarities to *S. pusilla* reflect convergence; song reminiscent of that of *S. passerina*, but molecular work suggests that the two are not sister-taxa. Race *browni* known only from three specimens from type locality (near Sombrerete, in W Zacatecas). Two subspecies recognized.
Subspecies and Distribution.
S. w. wortheni Ridgway, 1884 – SE Coahuila and SW Nuevo León, in NE Mexico.
S. w. browni Webster & Orr, 1954 – W Zacatecas, in NC Mexico.

Descriptive notes. 11–14 cm; 9·5–15 g. A small, slim, long-tailed sparrow. Male nominate race has crown rusty, becoming grey towards bill, grey nape; side of face greyish, with greyish-brown ear-coverts, buffy eyering, faint thin dark moustachial line and malar line (fainter in worn plumage); upperparts sandy brownish, mantle with dark brown streaks, rump plain grey; tail feathers dark brown with narrow greyish edges; upperwing dark brown, most feathers with pale greyish-buff edges, median and greater coverts with pale buff tips (forming two weak wingbars, which can largely disappear in worn plumage); throat white, underparts plain pale grey; iris dark; bill pink; legs black, or pink to pale orange (may vary seasonally). Female is very like male, but crown buffy brown, obscurely streaked blackish-slate, sometimes buffy brown on back, with ground colour a little more cinnamon, scapulars, secondaries and wing-coverts edged with buffy brown. Juvenile is similar to adult, but without rusty crown, and with prominent pale buffy eyering, and buffy postocular stripe, has dark streaks on head, breast and flanks. Race *browni* is said to be darker than nominate. VOICE. Song a high "peee churrrr", first note slurred, and usually on lower pitch, also described as a dry chipping trill suggesting song of *S. passerina*. Call a high, thin dry "tssip" or "tsip", sometimes repeated rapidly.
Habitat. Arid upland mesquite–juniper (*Prosopis–Juniperus*) and yucca–juniper (*Yucca–Juniperus*) grasslands with sparse shrubs. Appears to show preference for ecotones between gypsophilous grasslands (*Muhlenbergia*, *Hilaria* and *Bouteloua*) and desert scrub dominated by tarbush (*Flourensia cernua*), Berlandier's wolfberry (*Lycium berlandieri*), four-winged saltbush (*Atriplex canescens*), crown-of-thorns (*Koeberlinia spinosa*) and creosote bush (*Larrea tridentata*), with a few tree cholla (*Cylindropuntia imbricata*) and *Opuntia*, and perhaps with Russian thistle (*Salsola iberica*), and variety of other plants (*Machaeranthera*, *Croton*, *Zinnia* and *Ambrosia*). Found also in overgrown maize (*Zea mays*) fields. May forage in overgrazed pastures, but prefers pastures that are not overgrazed, with waist-high junipers. At 1200–2450 m.
Food and Feeding. Little information. Probably mostly seeds in winter, augmented with other plant food; insects e.g. moths (Lepidoptera), also spiders (Araneae). Forages on ground. Outside breeding season commonly in small flocks, formerly often of up to 50 individuals and exceptionally to 120; forms mixed flocks with *Pooecetes gramineus* and/or *S. pallida*.
Breeding. Peak of breeding activity in Zacatacas, Coahuila and Nuevo León in Jun and Jul, with juveniles observed in Aug; timing of nesting probably related to rains. Nest a cup woven from dry grasses, with finer lining, placed 0·1–1·5 m up in tarbush or thorn shrub, or close to (usually below 30 cm) or even on ground in weeds, usually of the mint family (Lamiaceae). Clutch 2–5 eggs, most commonly 3 (of six nests in Zacatecas, four had 4-egg clutches and two held 3-egg clutches; nests in Nuevo León and Coahuila contained 2 or 3 eggs), pale blue with brown to chestnut mottling at large end, resembling eggs of *S. pallida*. No information on incubation and nestling periods. Breeding success evidently very low, only 14% in one area and 0% in another; disturbance by livestock and predation seem to be main causes; snakes and coyotes (*Canis latrans*) thought to prey on nest contents.
Movements. Apparently sedentary; probably some short local movements in non-breeding season.
Status and Conservation. ENDANGERED. Rare and very local. Has extremely small range and population, both though to be decreasing. Global population probably no more than 100–120 mature individuals. Until very recently was known still to breed at only three locations (Las Esperanzas, in Nuevo León; and La India and Tanque de Emergencia, in Coahuila), at one of which population exceeds 50 individuals. In Jun–Jul 2006, three new breeding localities discovered, at La Carbonera and San Rafael, in Nuevo León, and at San José del Alamito, in Coahuila, with probable breeding also at El Erial–La Casita (in Nuevo León). Appears to be significantly affected by conversion of desert scrub to agriculture or livestock grazing; conservation measures should be geared to protect appropriate habitat. Formerly was found from SW New Mexico (and no doubt more widely in what is now SW USA) S through Mexican Plateau at least to Puebla. In New Mexico known only from type specimen, collected Jun 1884; in Mexico not recorded in C Chihuahua since 1959, no records from SW Tamaulipas since 1924, and last recorded in San Luis Potosí in 1951, in WC Veracruz in 1948 and in N Puebla in 1893. No records of race *browni* from Zacatecas (NW Sombrerete) since 1961; this poorly known race possibly extinct. Open shrub-grasslands have been severely reduced in extent by expansion of agriculture and grazing, and rate of habitat loss is increasing, mainly for potato-growing; unlikely that large tracts of suitable habitat survive near currently known sites. Very low reproductive success recorded, but effects on this on total population not known. Urgent conservation efforts required include implementation of full protection of all known breeding areas of this species and of other suitable areas of habitat.
Bibliography. Anon. (2010c), Behrstock *et al.* (1997), Butchart & Stattersfield (2004), Canales-del Castillo, González-Rojas *et al.* (2010), Canales-del Castillo, Klicka *et al.* (2010), Canales-Delgadillo *et al.* (2008), Collar *et al.* (1992), Garza de Leon *et al.* (2007), Howell & Webb (1995), Miller *et al.* (1957), Rising (1996a), Scott-Morales *et al.* (2008), Stattersfield & Capper (2000), Thayer (1925), Webster (1968), Wege *et al.* (1993).



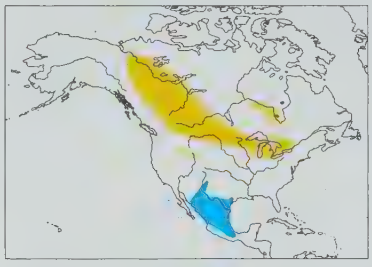
83. Black-chinned Sparrow

Spizella atrogularis

French: Bruant à menton noir **German**: Schwarzkinammer **Spanish**: Chingolo Barbinegro

On following pages: 84. Clay-colored Sparrow (*Spizella pallida*); 85. Brewer's Sparrow (*Spizella breweri*).

Taxonomy. *Spinites atrogularis* Cabanis, 1851, Mexico.
Probably closely related to *S. pusilla*, with which it shares many similarities in song and habitat, and *S. wortheni*, to which very similar in general appearance; mitochondrial DNA work on genus indicates that present species and *S. pusilla* are sister-taxa (*S. wortheni* may be closer to *S. breweri*). Present species is the only member of genus that exhibits sexual plumage dimorphism. Race *caurina* often synonymized with *cana*. Four subspecies generally recognized.
Subspecies and Distribution.
S. a. caurina A. H. Miller, 1929 – breeds in coast ranges of WC California from Contra Costa County S to San Benito County, occasionally N to S Oregon, in W USA; non-breeding range poorly known (one record from Santa Cruz I, in California).
S. a. cana Coues, 1866 – breeds in inner coastal mountains of C & SW California (from Monterey County S on W slopes of S Sierra Nevada) and extreme NW Mexico (N Baja California); non-breeding SW California S to S Baja California.
S. a. evura Coues, 1866 – breeds in SE California, S Nevada, SW Utah, C & SE Arizona, S New Mexico, W Texas and extreme N Mexico (NE Sonora); non-breeding range poorly known.
S. a. atrogularis (Cabanis, 1851) – C plateau of Mexico from Durango, S Coahuila and W Nuevo León S to C Oaxaca.



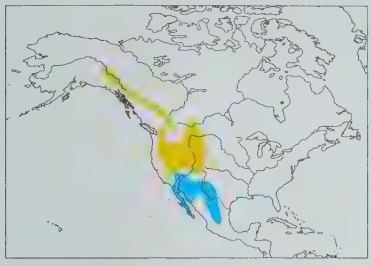
Descriptive notes. 14–15 cm; 9–14·8 g. A small, slim sparrow with long, notched tail. Male nominate race has grey head, with lores, area around base of bill and throat black (greyer in non-breeding plumage); upperparts cinnamon-brown to rufous-brown, streaked black, rump and uppertail-coverts grey or olive-grey; tail dark greyish-brown; upperwing mainly dark brown, feathers edged light buff, lesser coverts largely grey, median coverts with blackish-brown central area and broad buffy tips (during breeding, tips paler, forming wingbar), greater coverts and tertials broadly blackish on centre, tawny fringes broadest basally, narrower and paler buffy on tips, forming indistinct second wingbar (duller in worn plumage); chest and rest of underparts grey, palest on central belly and undertail-coverts; iris deep brown; bill bright pink; legs pinkish. Female is somewhat duller than male, has grey of head slightly washed brownish, black area of face smaller and greyer, thus less contrasting. Juvenile is like female, but without black on face, streaks above narrower, tertials edged pale rusty, chest grey, becoming nearly white on belly, and indistinctly streaked (variable) light grey. Race *evura* is paler than nominate, back sandy brown, black on throat restricted in extent; *cana* is shorter-tailed and smaller than nominate and previous, has underparts washed brownish; *caurina* is darker grey and less brown than other races, back richer cinnamon than in last. Voice. Song a clear ascending or descending trill, "sweet sweet sweet te te te te"; territorial males may countersing. Call a single thin "seep", "tsweet" or "cheep".
Habitat. Large tracts of undisturbed dry chaparral in foothills, and similar brushy habitats, commonly in tall and fairly dense sagebrush (*Artemisia*), manzanita (*Arctostaphylos*), ceanothus (*Ceanothus*) chaparral (dependent on frequent fires), often with scattered yucca (*Yucca*), also open juniper (*Juniperus*) woodlands, in rugged, rocky country. At 1200–2500 m; lower in winter.
Food and Feeding. Diet not well known. In winter principally seeds; in summer larval insects. Forages in variety of forbs, including pinyon (*Pinus*), juniper, coffeeberry (*Rhamnus californica*), mormon tea (*Ephedra nevadensis*) and chamise (*Adenostoma fasciculatum*). Gleans food from inner foliage and ground. Secretive and difficult to observe.
Breeding. Season middle to late Apr to early Jul, most activity mid-May to mid-Jun; probably single-brooded, perhaps occasionally two or three broods. Monogamous. May be loosely colonial. Nest a simple cup constructed from grasses, yucca fibres, stems, shredded bark, and perhaps a few small twigs or leaves, lined with finer material, in S California placed in big sagebrush (*Artemisia tridentata*) or California buckwheat (*Eriogonum fasciculatum*), less commonly in manzinita, oak (*Quercus*), desert ceanothus (*Ceanothus greggii*), holly-leaf cherry (*Prunus ilicifolia*) or redberry (*Rhamnus ilicifolia*), usually towards middle of shrub, mostly well concealed, at average height of c. 45 cm. Clutch 2–5 eggs, usually 3–4, pale greenish with scattered brown or blackish spots; replacement may be laid if first clutch lost; incubation by female, period 10–12 days; chicks fed by both parents, no information on duration of nestling period. Nests parasitized only very exceptionally by Brown-headed Cowbird (*Molothrus ater*).
Movements. Populations N of C Mexico migratory. Those breeding W of the Sierra and into N Baja California move S to C or S Baja California; migrant populations E of the Sierra move S to N & C Mexico (Sonora, Chihuahua, Coahuila). Arrivals of migrants in S part of breeding grounds from late Mar to early Apr, and correspondingly later farther N; in C & N California usually late Apr to early May, many not arriving until late May (presence in C California varies from year to year, depending on rainfall, sometimes entirely absent); reaches Great Basin early Apr to mid-Apr. S-bound movements not well known; breeding areas appear to be deserted by middle to late Aug. In 1955, an "extraordinary" autumn movement into SW Arizona took place following unseasonally heavy rains; many remained into winter and were identified as of race *cana*, which winters normally in S Baja California. Thus, migrations may vary in extent and geography depending on rainfall patterns.
Status and Conservation. Not globally threatened. Classified as "Highest Concern" in the USA (Red WatchList priority species for conservation). Generally uncommon and local; may be common in some places in optimum habitat. Global population estimated at 390,000 mature individuals. Declining in USA; Breeding Bird Survey data show average decrease in abundance of c. 5·4% per year during period 1966–2007. No information on population trends in Mexico. Characteristically found in large tracts of undisturbed habitat. Moves into areas in California a few years after fire, and may breed for several years in that area, before departing. Has suffered extensive habitat loss in recent decades. Main threats are continued degradation of habitat caused by mining activities, off-road vehicles, also fire suppression, as well as (especially in wintering range) overgrazing. Occurs within several protected areas, including Guadalupe Mountains National Park and Davis Mountains (Texas), Gray Ranch (New Mexico), Coronado National Forest (Arizona) and Vandenberg Air Force Base (California).
Bibliography. Anon. (1998), Armani (1985), Beadle & Rising (2002), Binford (1989), Grinnell & Swarth (1926), Hargrove (2010), Hellmayr (1938), Howell & Webb (1995), Lebbin *et al.* (2010), Miller *et al.* (1957), Phillips *et al.* (1964), Rising & Beadle (1996), van Rossem (1935), Russell & Monson (1998), Shackford (2003), Tenney (1997), Willoughby (1991).

84. Clay-colored Sparrow

Spizella pallida

French: Bruant des plaines **German**: Fahlammer **Spanish**: Chingolo Pálido

Taxonomy. *Emberiza pallida* Swainson, 1832, Carlton House, Saskatchewan, Canada.
Apparently closely related to *S. passerina* and *S. breweri*. Monotypic.
Distribution. Breeds in W & S Canada from WC Mackenzie, E British Columbia, Alberta, NW & C Saskatchewan and Manitoba (local and irregular in N) E to S Ontario and extreme S Quebec (rarely E to Gaspé Peninsula), S in USA to S Wisconsin, Michigan and New York (perhaps rarely S to SE South Dakota, NW Iowa, Illinois and N Indiana); non-breeding in S USA (S New Mexico and S Texas) and Mexico (S to Veracruz, Oaxaca and Chiapas), rarely Guatemala.



Descriptive notes. 12–13·5 cm; 9–15 g. A small, slim sparrow with long, notched tail. Has streaked crown with distinct cream-coloured median crownstripe and dark brown lateral crownstripe, broad whitish-buff supercilium, ochre ear-coverts, blackish eyestripe behind eye; blackish moustachial stripe, white submoustachial stripe and thin dark malar stripe; nape and side of neck grey; upperparts sandy brown to ochraceous buff, with bold blackish streaks, rump and uppertail-coverts plain and duller buffy-brown; tail brown; upperwing dark brown, feathers edged pale buff, median and greater coverts also with pale tips (forming two inconspicuous wingbars); throat whitish, underparts pale and unstreaked, with ochre breast; iris dark brown; bill reddish-flesh, dusky on culmen and near tip; legs pinkish or pale horn-coloured. Sexes similar. Juvenile is similar to adult, but crown clearly streaked with black, median stripe buffy, supercilium pale dull buff and indistinct, throat and flanks with distinct, thin brown streaks and spots. Voice. Song, occasionally at night, a series of 2–8 (usually 2–3) short, low-pitched, loud insect-like buzzes, "zee-zee-zee" or "buzz-buzz-buzz". Call a sharp "tsip", "chip" or "seep".
Habitat. Breeds in open, uncultivated brushy areas where shrubs interspersed in grasslands. In prairies characteristically found in rose (*Rosa*) or snowberry (*Symphoricarpos albus*) thickets, often along streams or around ponds; occurs also in alder (*Alnus*), willow (*Salix*) or poplar (*Populus*) parkland. In E, often in abandoned field with shrubs and small trees, and young conifer plantations. On migration may occur in mesquite (*Prosopis*) and other desert shrubs, thickets, open woodland and parks. In winter found in semi-arid grassland with small shrubs. Recorded from sea-level up to 2700 m.
Food and Feeding. Arthropods and seeds. Young fed mostly with Lepidoptera larvae, leafhoppers (Homoptera), adults and nymphs of grasshoppers (Orthoptera), spiders (Araneae), and damselflies (of family Coenagrionidae). In winter consumes variety of seeds, e.g. of alyssum (*Alyssum*), cockscomb (*Celosia*), lamb's quarters (*Chenopodium*), pigweed (*Axyris amaranthoides* and *Amaranthus retroflexus*), and various grasses. Forages low down and on ground. Gleans insects from low vegetation; takes seeds from ground or low seedheads. Outside breeding season usually in small flocks, often mixed with other sparrows, including *S. passerina* and *S. breweri*.
Breeding. Season late May to early Aug; sometimes double-brooded. Monogamous. Pair formation relatively quick after arrival of females on breeding grounds. Nest constructed by female, often accompanied by male, work takes 2–4 days to complete, a cup made from grasses, twigs and stalks, softer lining of fine grasses, hair and rootlets, placed near ground, usually below 30 cm, in bush, in Canadian Prairies mostly in snowberry. Clutch 3–5 eggs, usually 4, pale blue with brown markings; incubation by female, period 10–14 days, usually 11 days; chicks fed by both parents, nestling period 7–9 days; young not able to fly until 14 days old. Nests parasitized by Brown-headed Cowbird (*Molothrus ater*); in one study more than a third of all nests were parasitized, and usually only cowbird young survives.
Movements. Migratory. Migration routes largely through Great Plains, E of Rocky Mts and W of Mississippi; apparently, autumn migration may be slightly farther to W than that in spring. First obvious signs of movement N from Mexican border in late Mar/early Apr, movements along border zone continuing to mid-May. Arrival on breeding grounds from as early as late Apr, but usually in first week of May, and in Saskatchewan peak movements in mid-May; males arrive on breeding grounds 3–7 days before females. Post-breeding departure dates unclear (species becomes difficult to follow and track); remains on breeding grounds into Aug, some into early Sept, rarely Oct, although some moving S by early Aug, and some reach Texas by this time. Rare but regular on passage on both coasts; in California mainly a coastal migrant, peak late Sept to mid-Oct, and much rarer along W coast in spring. Casual visitor to Bermuda, Bahamas and Cuba.
Status and Conservation. Not globally threatened. Locally common to very common in appropriate habitat. In USA, rare but increasing in New York, rare in S Michigan, and apparently irregular at S limits of breeding range (South Dakota, NW Iowa, Illinois and N Indiana). In Mexican non-breeding range, common in Coahuila, incommon in S Baja California and Oaxaca.
Bibliography. Anon. (1998), Armani (1985), Beadle & Rising (2002), Binford (1989), Brooks (1974), Davis (2003), Dunning (2008), Fedak (1999), Fox (1961), Grant *et al.* (2006), Griffith (1992), Griscom (1932), Hellmayr (1938), Howell & Webb (1995), Knapton (1978, 1979a, 1979b, 1982, 1994), McCarthy (2006), Miller *et al.* (1957), Newman (1985), Rising & Beadle (1996), Root (1968), Russell & Monson (1998), Salt (1966), Seyffert (1988), Thurber (1986), Urban (1959), Walkinshaw (1939a), Warburton (1952), Willoughby (1991).

85. Brewer's Sparrow

Spizella breweri

French: Bruant de Brewer **German**: Nevadaammer **Spanish**: Chingolo de Brewer
Other common names: Timberline Sparrow (*taverneri*)

Taxonomy. *Spizella breweri* Cassin, 1856, western North America, California, and New Mexico = Black Hills, South Dakota, USA.
Apparently closely related to *S. passerina* and *S. pallida*. It has been suggested that race *taverneri* represents a distinct species, differing in habitat preferences; further study required. Two subspecies currently recognized.
Subspecies and Distribution.
S. b. taverneri Swarth & A. C. Brooks, 1925 – breeds in SE Alaska and W Canada (SW Yukon and NW & SE British Columbia and W Alberta) and N USA (W Montana); non-breeding range SW USA (Arizona E to W Texas) and probably N Mexico.
S. b. breweri Cassin, 1856 – breeds in S Canada (extreme S British Columbia, S Alberta and SW Saskatchewan) and W USA from E Montana, SW North Dakota and NE Colorado S to E & S California, S Nevada, C Arizona and NW New Mexico; non-breeding from S edge of breeding range S to NW & W Mexico (Baja California E to Coahuila, Nuevo León, San Luis Potosí, Guanajuato and Jalisco).
Breeds also in mountains from W Montana S to Colorado; race uncertain.
Descriptive notes. 12·5–15 cm; 8·9–14 g, *taverneri* larger (average 12·3 g), nominate 8·9–11·8 g.

A small, slim sparrow with long, notched tail. Nominate race has crown finely streaked with brown, without distinct median crownstripe (some individuals have a faint one), supercilium pale dull grey to dull whitish, lores pale, thin white eyering, dark eyestripe behind eye; ear-coverts brown, moustachial and malar stripes thin and brown; side of neck greyish-brown, faintly streaked; upperparts light brown with dark brown streaks or rows of spots, rump and uppertail-coverts plain brown; tail brown; upperwing dark brown, feathers edged narrowly pale buff, median and greater upperwing-coverts also with paler buff tips (forming two poorly defined wingbars); throat and underparts whitish, breast and flanks washed pale greyish-buff; iris dark brown; bill dull horn-brown to pale horn-pink, with dusky culmen and tip; legs pinkish or pale horn. Sexes similar. Juvenile is similar to adult, but less streaked above, with breast and flanks narrowly streaked with black triangular marks. Race *taverneri* is slightly larger than nominate, greyer (less brown) in coloration, with more contrast between grey breast and white belly, dorsal streaking coarser, head pattern bolder (approaching that of *S. pallida*), nape more heavily streaked, and bill darker and usually smaller. VOICE. Difficult to describe. Short song a "bzzzzzzz chip-chip-chip-chip-chip", second part slightly lower in pitch, and first part like a song of *S. pallida*; long song a sustained series of buzzing, bubbling, wheezing and canary-like trilling on different pitches. Call a weak "tsip", "chip" or "seep", like that of *S. pallida*.

Habitat. Throughout most of range found in shrubland dominated by big sagebrush (*Artemisia tridentata*); in winter in arid or semi-arid scrub with saltbush (*Atriplex*) and creosote bush (*Larrea tridentata*). Sometimes found in mountain mahogany (*Cercocarpus montanus*), rabbitbrush (*Chrysothamnus*) and pinyon–juniper (*Pinus* cf. *edulis–Juniperus*) grassland, or in bunchgrass prairie. Race *taverneri* in dwarf balsam fir–dwarf birch (*Abies–Betula*) habitat at or above timber-line. On migration and in winter occurs in variety of habitats, including weedy fields, edges of agricultural fields, and urban areas, and in creosote bush and other low xeric vegetation; in Arizona found in winter in open desert. Sea-level to 2500 m.

Food and Feeding. Few data on diet. Arthropods and seeds. Young fed mostly with Lepidoptera larvae, spiders (Araneae), bugs (Hemiptera) and leafhoppers (Homoptera). Forages low down and on ground. Gleans insects from low vegetation; takes seeds from ground and from low seedheads. In non-breeding season usually in small flocks, often mixed with other sparrows.

Breeding. Season mid-May through Jul; sometimes double-brooded. Monogamous. Occasional cooperative nesting recorded. Pairing within a few days of arrival of females on breeding grounds. Nest a cup of dry grass and sometimes sagebrush stems, lined with finer grasses, rootlets and commonly horsehair, placed low down near ground (rarely on ground), most (over 80%) of those of nominate race in thicker stand of big sagebrush, nests of *taverneri* in dwarf shrub or bush. Clutch 2–5 eggs, usually 3, blue-green with brown or rusty spots; incubation by female, rarely assisted by male, period 10–12 days, usually 11 days; chicks fed by both parents, nestling period c. 9 days. Proportion of nests parasitized by Brown-headed Cowbird (*Molothrus ater*) varies geographically, up to 50% in some places; usually abandons nest if parasitized.

Movements. Migratory; good evidence that populations farthest N leap-frog over S ones, and winter farthest S. Nominate race winters in Sonoran and Chihuahuan desert habitats from SW USA S into C Mexico; essentially, moves N and S, using lowland valleys as corridors for migratory passage. Migrants in Great Basin noted from mid-Mar, peak in Apr, and into early May; in S Canada (Alberta), more S and lowland nominate race arrives by early May, while more N and highland race *taverneri* arrives late May. Males reach breeding grounds approximately a week before females. In autumn, some depart by late Jul, many passing through SE Arizona in early Aug to mid-Aug, and migration can continue into early Oct; in lower Colorado Valley many present in early to middle Sept. N race *taverneri* begins to leave breeding areas from Aug, and gone by late Sept. Rare in autumn W to Pacific Coast and E to W Kansas and Oklahoma. Vagrant in E North America, recorded in autumn and winter in Minnesota, Nova Scotia, Massachusetts and Louisiana, and in spring in Ontario and Illinois.

Status and Conservation. Not globally threatened. Classified as "Declining" in the USA (Yellow WatchList priority species for conservation). Often common or very common in appropriate habitat. Numbers apparently declining significantly in much of W part of range owing to habitat destruction. Main threats are fragmentation and destruction of sagebrush habitat through agricultural expansion and overgrazing, as well as altered fire regimes; frequent fires enables invasive grasses to become dominant, and suppression of fire allows growth of pinyon–juniper woodland. This species occurs in several protected areas.

Bibliography. Anon. PLATE 49

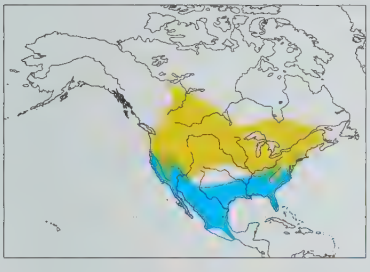
inches 3

cm 8



Genus *POOECETES* S. F. Baird, 1858

86. **Vesper Sparrow**

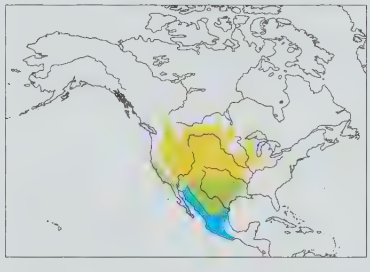
Pooecetes gramineus

French: Bruant vespéral **German**: Abendammer **Spanish**: Chingolo Coliblanco
Other common names: Oregon Vesper Sparrow (*affinis*)

Taxonomy. *Fringilla graminea* J. F. Gmelin, 1789, New York, USA.
Perhaps close to *Melospiza* and some *Ammodramus* species. Geographical variation largely clinal. Proposed race *altus* (described from Kendrick Park, in NC Arizona), treated as a synonym of *confinis*. Three subspecies recognized.
Subspecies and Distribution.
P. g. confinis S. F. Baird, 1858 – breeds in SW Canada (C British Columbia and SW Mackenzie E through C Saskatchewan and S Manitoba to W Ontario) and S in USA to CE California, C Nevada, C Arizona, C New Mexico, E Colorado and W Nebraska; non-breeding from S edge of breeding range (California E to New Mexico) and from S Texas S in Mexican highlands (to Oaxaca), occasionally to Guatemala.
P. g. affinis G. S. Miller, 1888 – breeds in W Washington and W Oregon (W USA); non-breeding from C California (W of Sierra Nevada) S to NW Mexico (NW Baja California, possibly also Chihuahua).
P. g. gramineus (J. F. Gmelin, 1789) – breeds in SE Canada (NE Ontario and S Quebec E to Prince Edward I and N Nova Scotia) and E USA from N Minnesota E to Maine and S to C Missouri, C Kentucky, NE Tennessee, C North Carolina and S Virginia; non-breeding from S part of breeding range S to C Texas and Gulf Coast.

Descriptive notes. 14–18 cm; 19·5–28·3 g. A medium-sized sparrow with fairly large, conical bill, much white in outer tail feathers. Nominate race breeding has crown and nape greyish-brown, conspicuously streaked dark brown, supercilium and submoustachial stripe often largely unstreaked whitish, greyish or buffy (paler than other facial markings, but not distinct), whitish line on central forehead, white eyering; ear-coverts pale in centre, dark towards rear; moustachial and malar stripes brown; nape and upperparts greyish-brown, dark centres of feathers giving conspicuously streaked appearance, rump less boldly streaked than back; tail brown, outer web and tip of outermost feather pair white, adjacent one variable but usually some white in outer web (in flight, outer tail flashes conspicuously white); upperwing dark brown, lesser upperwing-coverts rusty, tips of median and greater coverts light buff or buffy white (forming one or two indistinct wingbars), tertials narrowly edged buffy or buffy white; throat buffy white with indistinct dark spotting; underparts dull whitish, breast and flanks narrowly streaked brown, belly white, undertail-coverts whitish; iris light brown or brown; bill flesh-coloured, broadly dusky on culmen; legs pinkish. In fresh non-breeding plumage, generally more buffish (less grey) in appearance, and underparts faintly tinged buff. Sexes similar in coloration. Juvenile is like adult, but buffier. Races differ minimally: *affinis* is relatively small, upperparts somewhat more buffish; *confinis* is on average somewhat larger, with relatively longer, more slender bill. Voice. Song, from tree or exposed perch, sweet and musical, generally 2–4 long clear notes, often with downward slurs, followed by shorter flute-like trills, often rising and then falling in pitch; reminiscent of song of *Melospiza melodia*, but sweeter and more plaintive; occasional flight song given. Call a sharp "chirp".
Habitat. Dry open grasslands with sparse and patchy herbaceous vegetation, fields, and brushy second growth; sometimes in openings in pine–oak (*Pinus–Quercus*) woodlands, oldfields, and reclaimed strip mines. In winter found in arid tropical scrub. Sea-level to 2500 m.
Food and Feeding. Diet mainly small invertebrates and seeds. Invertebrates taken include beetles (Coleoptera), grasshoppers (Orthoptera), caterpillars (Lepidoptera), spiders (Araneae). Consumes grass and weed seeds, also waste grain. Forages principally on or near ground and low in vegetation; runs or hops on ground. Sometimes uses a double-scratch when searching for arthropods in litter; also gleans insects from low vegetation. Will perch on fences or trees. Generally singly; on migration also often in small loose flocks.
Breeding. Season Apr–Aug; generally one or two broods, occasionally triple-brooded. Monogamous; occasionally polygynous. Males arriving late on breeding grounds often have trouble in pairing. Nest shallow cup of dry grasses, lined with finer vegetation, rootlets, hair and sometimes feathers, placed on ground, sometimes in depression and often well hidden by grass, at other times in much more open situation. Clutch 3–5 eggs, usually 4 (occasionally 6), whitish with lavender to brownish-red speckling; incubation by female, period 12–13 days; chicks fed by both parents, nestling period at least 9 days. A relatively frequent host of Brown-headed Cowbird (*Molothrus ater*), but little information on effects on breeding success.
Movements. Mostly migratory. Spring migration from mid-Feb to early May; in Colorado Valley passage through to Apr, arrival in Oregon as early as late Feb/early Mar W of Cascades and late Mar/early Apr E of Cascades; moves through Great Plains late Mar to early May, peak in Great Lakes region early to late Apr. Males arrive on breeding grounds a week before females. Autumn migration from mid-Aug through mid-Nov, with peak movements Sept to early Oct; all have left Alberta by mid-Sept, and Great Lakes region most gone by late Oct, some lingering into Nov. In N Mexico (Sonora) most migration in Nov and Mar. Nominate race casual in winter in E & SE Mexico (Tamaulipas and Yucatán) and Bermuda. Migrates in small groups or loose flocks, sometimes with Horned Larks (*Eremophila alpestris*) or *Passerculus sandwichensis*.
Status and Conservation. Not globally threatened. Race *affinis* listed as a "California Bird Species of Special Concern" (wintering population). Locally common in appropriate habitat. Changes in farming practices appear to be correlated with changes in the species' range and abundance in E, where it probably was not common in pre-Columbian times. In W, will benefit from management to preserve dry grassland. Overgrazing of desert grassland has destroyed much of wintering habitat; greatest remaining threat is development of the largely flat and open grassland used during non-breeding period.

Bibliography. Adams *et al.* (1994), Beadle & Rising (2002), Best & Rodenhouse (1984), Binford (1989), Cardiff (1965), David *et al.* (2009), Dawson & Allen (1960), Dawson & Evans (1960), Grant *et al.* (2006), Hellmayr (1938), Howell & Webb (1995), Hubbard (1972a), Hubbard & Crossin (1974), Jones & Cornely (2002), Klicka & Spellman (2007), Kroodsma (1972), McCarthy (2006), Miller *et al.* (1957), Nelson & Martin (1999), Ohmart & Smith (1971), Perritt & Best (1989), Phillips *et al.* (1964), Pyle (1997), Reed (1985, 1986), Ridgway (1901), Rising & Beadle (1996), Ritchison (1980, 1981a), Rodenhouse & Best (1983, 1994), Russell & Monson (1998), Schroeder (1972), Shuford & Gardali (2008), Sutton (1941), Swain (1987), Wells & Vickery (1994), Wray & Whitmore (1979).



Genus *CHONDESTES* Swainson, 1827

87. **Lark Sparrow**

Chondestes grammacus

French: Bruant à joues marron **German**: Rainammer **Spanish**: Chingolo Arlequín

Taxonomy. *Fringilla grammaca* Say, 1822, Bellefontaine, 4 miles [6·4 km] from mouth of Missouri River, Missouri, USA.
Probably close to *Calamospiza* and *Amphispiza*. Geographical variation largely clinal; races poorly differentiated. Proposed race *quillini* (described from Cotulla, Texas) included within *strigatus*. Two subspecies generally recognized.
Subspecies and Distribution.
C. g. strigatus Swainson, 1827 – breeds in S Canada from S interior British Columbia and SE Alberta E to S Saskatchewan and S Manitoba, and W USA from Oregon E to the Dakotas and S to S California, C Nevada and S Arizona (Chiricahua Mts), S to N Mexico (N Sonora E to Coahuila, S to Zacatecas, Nuevo León and W Tamaulipas); non-breeding from S edge of breeding range S to S Louisiana and Mexico (S, except Yucatán Peninsula and adjacent lowlands, to S Baja California, Veracruz and Chiapas).
C. g. grammacus (Say, 1822) – breeds from Minnesota and C Wisconsin S to Texas, E to Ohio, Mississippi Valley and Louisiana; non-breeding from C Texas and S Louisiana S through C Mexico to Guerrero and Oaxaca.

Descriptive notes. 14·1–18·3 cm; 24·7–33·3 g. Fairly large, long-tailed sparrow with strongly patterned face and much white in tail. Nominate race has white or light beige median crownstripe, rusty or chestnut lateral crownstripe (becoming blacker towards bill), long, broad white supercilium becoming buffier towards rear, thin black eyestripe, white crescent under eye, chestnut ear-coverts with white spot at posterior, white submoustachial stripe, prominent black malar stripe becoming broader towards neck, and white throat; nape warm brown, slightly streaked darker brown; upperparts sandy-brown with conspicuous dark brown stripes, lower back and rump brown and unstreaked; tail brown, 3–5 outer pairs of rectrices boldly tipped white, outermost two also edged with white; upperwing dark brown, feathers edged pale buff, bases of primaries conspicuously pale (producing rather distinct band), median and greater coverts with pale buff or whitish tips (forming two indistinct wingbars); breast pale beige with bold brown central patch, flanks pale beige, belly dull white, undertail-coverts dull white; iris dark brown; bill pale horn to greyish, upper mandible often much duskier grey; legs dull flesh-coloured. Sexes similar in coloration. Juvenile is similar to adult, but with heavily streaked underparts, head markings brown, not rusty, and has supercilium and submoustachial stripe duller. Race *strigatus* is overall paler than nominate, and has duller chestnut colour on head and narrower streaking above. Voice. Song musical and variable, a broken series of clear notes, "twee twee trerere trerere twee twee twee", introduced with 1 or 2 clear notes. Call a sharp, distinctive, parulid-like "tslip" or a metallic "cheep", often given in flight.
Habitat. Open habitats with heavily grazed grassland, bare ground and scattered trees. In Great Plains often in floodplains of rivers, with scattered eastern cottonwoods (*Populus deltoides*) and other trees; in W part of range in grasslands with sagebrush (*Artemisia*), greasewood (*Sarcobatus vermiculatus*) and mesquite (*Prosopis*); in Utah, juniper (*Juniperus osteosperma*) or mixed brush juniper–big sagebrush (*Artemisia tridentata*), and rocky canyons with springs. In winter, often in agricultural lands with scattered trees and hedgerows, open weedy fields, suburbs; in Colima and Jalisco (W Mexico) in grassy coastal plains, semi-open thorn-scrub and arid pine–oak (*Pinus–Quercus candicans*) forest with pines to 15 m tall and sparse grass (*Andropogon*), at 300–2400 m. Generally from sea-level up to 2500 m.
Food and Feeding. Diet c. 75% granivorous and 25% insectivorous. Insects taken include 14% orthopterans, also adult beetles (Coleoptera), larval lepidopterans, and adult flies (Diptera). Dominant seeds eaten vary seasonally, include bristlegrass (*Setaria leucophila*), panicgrass (*Panicum*), ragweed (*Ambrosia*), wheat (*Triticum*) and, on W coast, redmaids (*Calandrinia caulescens*), oats (*Avena*), knotweed (*Polygonum*). Forages principally on or near ground and low in vegetation. Comparatively tame. In non-breeding season often in small flocks.
Breeding. Season mid-Apr through Jul; usually single-brooded. Monogamous. Pairs formed soon after arrival on breeding grounds. Nest-site selected by both sexes, final choice apparently by female, nest a cup of dry grass and twigs, lining of finer grasses, rootlets, hair and sometimes leaves, placed on ground, often at base of bunchgrass or small cactus, less commonly to 3 m up in tree or shrub, often near area of sandy soil; old nest of other species occasionally used. Clutch 3–6 eggs, usually 4 or 5, creamy or greyish-white with blackish, brown or purplish spots and scrawls; incubation by female, period 11–12 days; chicks fed by both parents, nestling period 11–12 days. Commonly parasitized by Brown-headed Cowbird (*Molothrus ater*).
Movements. Most populations migratory; present all year S USA (California, S Arizona, New Mexico, Texas) and Mexico. Some tendency for nomadic movements, perhaps a result of anomalies in rainfall. Spring migration late Mar through May; arrival in S latitudes mid-Mar, peak migra-

Sage Sparrow (*Artemisiospiza nevadensis*); 92. Tumbes Sparrow (*Rhynchospiza stolzmanni*); 93. Stripe-capped Sparrow (*Rhynchospiza strigiceps*); 94. Stripe-headed Sparrow (*Peucaea ruficauda*); 95. Black-chested Sparrow (*Peucaea humeralis*); 96. Bridled Sparrow (*Peucaea mystacalis*); 97. Cinnamon-tailed Sparrow (*Peucaea sumichrasti*); 98. Rufous-winged Sparrow (*Peucaea carpalis*); 99. Cassin's Sparrow (*Peucaea cassinii*); 100. Bachman's Sparrow (*Peucaea aestivalis*); 101. Botteri's Sparrow (*Peucaea botterii*).

tion for US middle latitudes mid-Apr through May; in Sonora (N Mexico) moves N from mid-Mar through Apr, with latest recorded in mid-May; in California and Oregon migrants seen late Apr to mid-May. After breeding some adults depart very early, from mid-Jul/Aug, and movements S may continue until Nov; in middle latitudes of USA migrants present late Aug to mid-Oct, and in California most migration over by late Sept; in lower Colorado Valley migrants observed by mid-Aug, but in Sonora first arrivals may begin late Jul, although peak movements in Sept. Rare visitor to E coast during autumn, and vagrant during spring; recorded as far N as Newfoundland. Vagrant to various parts of S, including Yucatán, Guatemala, El Salvador, Honduras, Cuba, Jamaica, N Bahamas and Bermuda, with sight reports from Panama; also vagrant to W Palearctic, where recorded twice in British Is.

Status and Conservation. Not globally threatened. Fairly common to locally very common; rare in S Ontario (Canada). Has declined in E parts of range, where nominate race, until fairly recently, bred E to SE Canada (S Ontario) and, in USA, to C Pennsylvania, W North Carolina and C Alabama. In pre-colonial times found only in W North America; moved E with clearing of forests. As marginal farms have reverted to woodland, this species, which is often found in grazed habitats, has suffered habitat loss and has decreased in numbers.

Bibliography. Anon. (1998), Beadle & Rising (2002), Charlton (1991, 1995), Crowell *et al.* (1982), Griscom (1932), Hellmayr (1938), Houston & Houston (2001), Howell & Webb (1995), Hubbard (1972a), Lusk *et al.* (2003), Markle (1946), Martin & Parrish (2000), McNair (1984, 1985), Miller *et al.* (1957), Newman (1970), Peck & James (1987), Pyle (1997), Raffaele *et al.* (1998), Renwald (1977), Ridgway (1901), Rising & Beadle (1996), Russell & Monson (1998), Urban (1959), Veit (2000), Walley (1985), Whitaker (1957), Zimmerman (1993).

Genus *AMPHISPIZA* Coues, 1874

88. Five-striped Sparrow

Amphispiza quinquestriata

French: Bruant pentaligne **German**: Fünfstreifenammer **Spanish**: Chingolo Cincorrayas

Taxonomy. *Zonotrichia quinquestriata* P. L. Sclater and Salvin, 1868, Mexico, probably Bolaños, in Jalisco.

Genus has sometimes been subsumed into *Aimophila*, but this treatment not supported by molecular-genetic findings, which indicate that the two are not closely allied; juvenile plumages also different. Recent molecular work suggests that present genus is in a clade that contains also *Calamospiza*, *Chondestes* and *Spizella*; also that present species is close to *A. bilineata*. Two subspecies recognized.

Subspecies and Distribution.

A. q. septentrionalis (van Rossem, 1934) – extreme S USA (SC Arizona) and NW Mexico (E Sonora and W Chihuahua S to C Sinaloa and W Durango).

A. q. quinquestriata (P. L. Sclater & Salvin, 1868) – N Jalisco, in W Mexico.

Descriptive notes. 13–16 cm; 17·1–21·7 g. A medium-sized, long-tailed, rather dark sparrow. Nominate race has crown, nape and side of face brownish-grey, white narrow supercilium, submoustachial stripe and broken eyering, broad black malar stripe; chin and throat white; upperparts reddish-brown mixed with grey, without conspicuous markings, rump and uppertail-coverts brownish; tail feathers dark brown with lighter edges; upperwing dark brown, upperwing-coverts with warmer and paler brown edges; breast and flanks dark grey, contrasting with white throat, black central breast spot; belly whitish, undertail-coverts grey with pale edges; iris dark; upper mandible blackish, lower mandible paler bluish-grey; legs dull pinkish-flesh. Sexes similar. Juvenile has crown and back brown, spotted darker brown, lower back and rump without streaking, tail dark with tips of outer rectrices white, primaries edged whitish and secondaries and wing-coverts edged rusty, underparts mottled yellowish and brownish, undertail-coverts brown with yellowish tips, lacks blackish malar stripe and breast spot. Race *septentrionalis* is larger and paler than nominate, and has smaller chest spot. Voice. Song staccato and brief, lasting just over a second, usually composed of introductory note followed by several note complexes, each usually repeated two or three times, e.g. "tsi-gp tsi-gp twsee tweep" or "chip chip chip pt pt pt"; after pause of a few seconds, a series may be repeated, up to 18 phrases per minute. Call "chuck", "pip" and "seet".

Habitat. Dense desert scrub and tropical thorn-scrub, also tropical deciduous woodland, in canyons and often on rocky well-vegetated hillsides. At 50–1850 m.

Food and Feeding. Diet seeds, fruit (*Celtis*, *Anisicanthus*), also insects, primarily caterpillars and moths (Lepidoptera), grasshoppers (Orthoptera) and ants (Formicidae); young fed primarily with grasshoppers and caterpillars. Forages principally on ground and low in shrubs; shy. Outside breeding season usually in pairs and small flocks.

Breeding. Probably coincides with first major summer rainstorm; early Jun, usually not until mid-Jul (Arizona and Sonora), to Sept; probably single-brooded. Monogamous. Nest built by female alone, a deep cup constructed from dry grasses and stems, lined with finer vegetation and hair, including that of Collared Peccary (*Pecari angulatus*), placed in grass clump or in shrub, sometimes at base of an ocotillo (*Fouquieria*), generally 19–150 cm above ground. Clutch 3–4 eggs, most commonly 4, whitish to pale blue and unmarked; incubation by female, period 12–13 days; chicks fed by both parents, nestling period 9–10 days. Commonly parasitized by Brown-headed Cowbird (*Molothrus ater*).

Movements. Probably non-migratory. Some individuals breeding in N of range (Arizona and N Sonora) may move S in winter.

Status and Conservation. Not globally threatened. Classified as "Rare" in the USA (Yellow WatchList priority species for conservation). Status not well known. Often common in appropriate habitat. Only relatively few individuals found N into extreme S USA. Has small range, with estimated global population c. 200,000 mature individuals; US population probably no more than 60–70. Numbers thought to be decreasing.

Bibliography. Anon. (1998), Armani (1985), Beadle & Rising (2002), Groschupf (1985, 1992, 1994), Groschupf & Mills (1978, 1982), Hellmayr (1938), Howell & Webb (1995), Lebbin *et al.* (2010), Mills (1977), Mills *et al.* (1980), Phillips & Farfan (1993), Rising & Beadle (1996), Russell & Monson (1998), Storer (1955), Wolf (1977).

89. Black-throated Sparrow

Amphispiza bilineata

French: Bruant à gorge noire **German**: Schwarzkehlammer **Spanish**: Chingolo Gorjinegro

Taxonomy. *Emberiza bilineata* Cassin, 1850, Texas, on Rio Grande, USA.

Genus has sometimes been subsumed into *Aimophila*, but this treatment not supported by molecular-genetic findings, which indicate that the two are not closely allied; juvenile plumages also different. Recent molecular work suggests that present genus is in a clade that contains also *Calamospiza*, *Chondestes* and *Spizella*; also that present species is close to *A. quinquistriata*. Several other races proposed: *dapolia* (described from Chisos Mts, Texas) included within *opuntia*; in SW Gulf of California, *carmenae* (Carmen I) and *sanctissima* (Espiritu Santo I) both synonymized with *bangsi*; *confinis* (Chihuahua Municipality, C Chihuahua) treated as a synonym of *grisea*. Nine subspecies recognized.

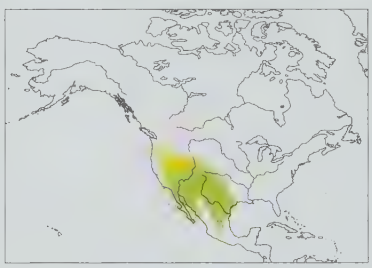
Subspecies and Distribution.

A. b. deserticola Ridgway, 1898 – breeds in W USA from C Washington, Oregon, NE California, N Nevada, S Idaho, N Utah, SW Wyoming and W Colorado S through Great Basin to NW Mexico (NE & C Baja California S, including Cedros I, Natividad I and Ángel de la Guarda I, to c. 27° N, E to NW Chihuahua); non-breeding in S third of breeding range and S into N Sonora (Mexico).

A. b. opuntia Burleigh & Lowery, 1939 – breeds in SE Colorado and NW Oklahoma S through E New Mexico and W Texas (USA) S to N Mexico (NW Coahuila); non-breeding in S parts of breeding range.

A. b. bilineata (Cassin, 1850) – S USA (NC Texas) S to NE Mexico (E Coahuila, Nuevo León and lower elevations of Tamaulipas).

A. b. bangsi Grinnell, 1927 – S Baja California (S from c. 26° N), including nearby islands (except Tortuga I and Cerralvo I), in NW Mexico.



A. b. tortugae van Rossem, 1930 – Tortuga I, in WC Gulf of California (S Baja California).

A. b. belvederei Banks, 1963 – Cerralvo I, in SW Gulf of California (S Baja California).

A. b. pacifica Nelson, 1900 – C & S Sonora (including Tiburón I and San Pedro Nolasco I, in E Gulf of California) and N Sinaloa, in NW Mexico.

A. b. cana van Rossem, 1930 – San Esteban I, in E Gulf of California.

A. b. grisea Nelson, 1898 – NC Mexico from C Chihuahua, S Coahuila, San Luis Potosí and SW Tamaulipas S to N Jalisco, Guanajuato, Querétaro and Hidalgo.

Descriptive notes. 12–14·5 cm; 10·2–16·4 g. A small to medium-sized sparrow with distinctive plumage. Nominate race has crown and upperparts grey, mantle and scapulars washed brown; white supercilium thinly outlined with black; side of face grey, becoming black on cheek and lores, white lower half of eyering, broad white submoustachial stripe not reaching bill base; tail dark greyish-brown to blackish, outer rectrices with white outer webs, outermost two also tipped white (tail feathers often worn); upperwing dark brown, feathers edged grey-brown; chin and throat black, black extending to centre of breast; rest of underparts pale greyish-white, flanks washed buffish, undertail-coverts more irregularly so; iris dark greyish-brown; upper mandible blackish, lower mandible bluish; legs dark grey or black. Sexes similar in coloration, male slightly larger than female. Juvenile has crown dark grey-brown, lores and ear-coverts grey, partial white eyering, supercilium white, nape to back brown-grey, rump greyish or brownish-grey, tail as on adult; wing blackish (not so dark as tail), wing-coverts and tertials edged light rusty brown, median and greater coverts also with pale buff tips (forming two indistinct wingbars); throat mottled with grey, breast to upper belly and flanks finely streaked grey, lower belly and undertail-coverts light buffy. Races differ mainly in colour of upperparts and size: *deserticola* is large, with reddish-brown back; *opuntia* also is large, with medium to pale grey back with brown tinge; *bangsi* is smaller than *deserticola* and is darker and more greyish; *belvederei* is like previous, but slightly darker and greyer above, upper mandible slightly more decurved; *pacifica* resembles nominate, but smaller tail spots; *tortugae* is darkest race, colour more saturated; *cana* is smallest and greyest race, more white in tail than *deserticola*; *grisea* is like *deserticola*, but very much darker, and darker and less brown above than nominate. Voice. Song, heard through spring and summer (and occasionally at other times) variable and complex, difficult to describe, a sweet tinkling warble. Call a high "sii".

Habitat. Open arid areas with scattered bushes and cacti, from sea-level to 2500 m. Common in alluvial fans, washes and canyons. Most common where mesquite (*Prosopis*), palo verde (*Cercidium microphyllum*) and creosote bush (*Larrea tridentata*), ocotillo (*Fouquieria splendens*), catclaw acacia (*Acacia greggii*), blackbrush (*Coleogyne ramosissima*), sagebrush (*Artemisia*), antelope brush (*Purshia tridentata*), rabbitbrush (*Chrysothamnus*) and various cacti are common and (depending on locality) interspersed with Joshua trees (*Yucca brevifolia*), pinyon–juniper (*Pinus* cf. *edulis–Juniperus*) or other vegetation. In SE Colorado, E New Mexico, W Texas and Oklahoma prefers short pastureland with scattered mesquite, yucca, prickly-pear and cholla (*Opuntia*); in Oregon and Idaho breeds on barren grassy hillsides with scattered sagebrush and rabbitbrush and saltbush (*Atriplex*).

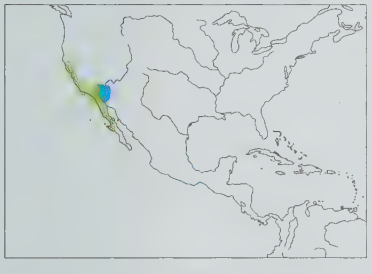
Food and Feeding. Diet during breeding season mainly arthropods, including grasshoppers (Orthoptera), mantids (Mantodea), walking sticks (Phasmida), caterpillars (Lepidoptera), robber flies (Asilidae) and dragonflies (Odonata), as well as a variety of grass seeds; in non-breeding season, almost exclusively dried grass seeds, e.g. of *Aristida*, *Paspalum*, *Amaranthus*, *Panicum*. Forages principally on or near ground, usually near or under shrubs or low in vegetation. Picks food items from ground, also gleans from low vegetation. Capture of some arthropods (e.g. grasshoppers) involves flushing and short aerial chases. In pairs and in small groups outside breeding season.

Breeding. Mainly Apr–May, sometimes from as early as Feb, and recently fledged young seen in Aug in N Mexico (Coahuila); sometimes two broods, when nesting in mid-Jun stimulated by monsoon rains. Monogamous. Nest built by female, a cup made from grasses, twigs and rootlets, lined with finer grasses and hair, placed close to ground, average c. 35 cm up, in shrub. Clutch 2–5 eggs, usually 3–4, white to bluish-white and unmarked; incubation by female, period 12 days; chicks fed by both parents, nestling period on average 9·5 days. Regularly parasitized by Brown-headed Cowbird (*Molothrus ater*), which significantly reduces clutch size of host by damage of eggs and egg removal.

Movements. N populations migratory, and individuals in many populations move downslope in winter; S populations resident. In USA, arrival in S California from mid-Mar, farther N (in Nevada, Oregon and Idaho) in Apr and early May; arrivals similarly timed towards E (Texas Colorado, Oklahoma). In autumn, leaves breeding grounds late Aug and Sept, reaching wintering grounds from early Sept. Casual visitor (probably race *deserticola*) in non-breeding season N to SW Canada (SW British Columbia, S Alberta, S Manitoba) and W Montana E to Atlantic coast and Florida Panhandle.

Status and Conservation. Not globally threatened. Often common or very common in appropriate habitat; local in Oregon. Populations in USA seem to be declining, probably primarily because of urban development and clearing of mesquite for agricultural purposes.

(1998), Austin & Smith (1974), Banks (1968), Beadle & Rising (2002), Bowers & Dunning (1985), Brunton & Pratt (1986), Casper (1980), Coe & Rotenberry (2003), Du Bois (1959), Gustafson (1975), Heckenlively (1967, 1970), Hellmayr (1938), Hewes (1971), Howell & Webb (1995), Hunn (1978), Jannssen (1974), Johnson & van Riper (2004), Johnson *et al.* (2002), Meier (1974), Menk & Stevenson (1978), Miller *et al.* (1957), Phillips *et al.* (1964), Pidgeon *et al.* (2003, 2006), Rising & Beadle (1996), Russell & Monson (1998), Schwilling (1954), Scott *et al.* (1971), Smyth & Bartholomew (1966), Storer (1955), Urban (1959), Wolf (1977).



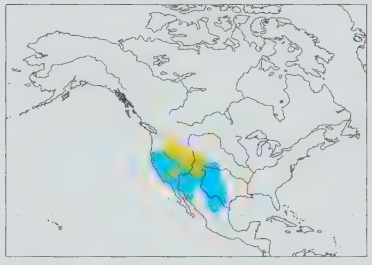
Genus *ARTEMISIOSPIZA* Klicka & Banks, 2011

90. Bell's Sparrow

Artemisiospiza belli

French: Bruant de Bell **German**: Beifußammer **Spanish**: Chingolo de Bell
Other common names: Bell's Sage Sparrow; Saltbush Sparrow (*canescens*); San Clemente Sage Sparrow (*clementeae*)

Taxonomy. *Emberiza belli* Cassin, 1850, near Sonoma, California, USA.
Until recently placed in genus *Amphispiza*, and considered conspecific with *A. nevadensis*, but recent molecular work indicates that the two are, instead, members of a well-resolved clade of "grassland" sparrows that includes genera *Pooecetes*, *Oriturus*, *Passerculus*, *Ammodramus* (in part), *Melospiza* and *Xenospiza*. Present genus newly erected to accommodate these two species. Race *canescens*, closely similar in appearance to *A. nevadensis* and possibly hybridizing with it where ranges meet, has been thought perhaps to represent a separate species; further research required. Race *cinerea* intergrades with nominate in NC Baja California. Race *clementeae* should perhaps be subsumed into nominate. Four subspecies provisionally recognized.
Subspecies and Distribution.
A. b. belli (Cassin, 1850) – California on W slopes of C Sierra Nevada (S to Mariposa County) and coastal ranges (from Trinity County and Shasta County) S to extreme NW Mexico (NW Baja California S to c. 29° N).
A. b. clementeae (Ridgway, 1898) – San Clemente I, off SW California.
A. b. cinerea (C. H. Townsend, 1890) – C Baja California (S to 26° N).
A. b. canescens (Grinnell, 1905) – breeds in interior SC California (S San Joaquin Valley, Inyo region, and S & W edges of Mojave Desert) and adjacent W Nevada; non-breeding also W to SW California, E to S Nevada and W Arizona, and S to NE Baja California.



Descriptive notes. 13·7–15·7 cm; 12·7–16·8 g. A medium-sized sparrow, with long tail often held cocked. Nominate race has head and nape brownish-grey, crown faintly streaked; supraloral spot and eyering white, lores dark, ear-coverts grey; narrow dark moustachial stripe, broad white submoustachial stripe and broad dark malar stripe; upperparts brownish with obscure streaking, rump brown; tail dark brown, outer web and tip of outer rectrices white (in unworn plumage); upperwing dark brown, feathers edged buff, median and greater coverts also with pale buff tips (forming two obscure wingbars); throat white; underparts buffy white, sides and flanks buffier and streaked dark, conspicuous dark brown central breast spot, belly dull white; iris dark brown; bill greyish, upper mandible often mostly duskier; legs dull brownish-red, greyer and often darker on feet. Sexes similar. Juvenile is dark brown, greyer on head and paler below, with streaked crown, back and breast, pale brown superciliary stripe, two broken buff wingbars. Race *clementeae* is very similar to nominate, but with larger bill, perhaps paler coloration, and with eyering and supraloral spot buffy; *cinerea* is paler; *canescens* is paler than nominate, and has streaking on crown and upperparts distinct (indistinct on nominate). Voice. Song described as "tweesitity-slip tweesitity-slip swer". Call a short, bell-like "tink".
Habitat. Generally in dry chaparral and coastal sage scrub, inland valleys, and lower foothills. Characteristic of dense chamise (*Adenostoma fasciculatum*), but also in California sagebrush (*Artemisia californica*), or brittlebush (*Encelia farinosa*), and mixed brush on sand dunes near coast; found in *Lycium* ("frutilla") in Baja California. Sea-level to 1400 m. Race *canescens* characteristically found in desert scrub where saltbush (*Atriplex*) prevalent; to 2500 m on E side of Sierra Nevada.
Food and Feeding. Variety of animal and plant items. Generally seeds and other vegetable matter. Young fed with insects. Forages principally on or near ground and low in vegetation. Typically, runs on ground, tail held cocked. In open country tends to run from bush to bush; in closed situations moves under vegetation, making it difficult to see. Resident populations remain in pairs throughout non-breeding season.
Breeding. Season late Mar to Jun (*canescens*), or mid-Apr to mid-May through early Jun (nominate). Probably monogamous. Singing and territory maintenance may begin in Jan–Feb. Nest built by female, taking 6–8 days, a cup of coarse grasses, with lining of finer grasses, wool and hair, placed low in bush, to c. 0·7 m up, usually not on ground; nominate race often in brittlebush, chamise, black sage (*Salvia mellifera*), California buckwheat (*Eriogonum fasciculatum*), California sagebrush, and the like, *clementeae* in boxthorn (*Lycium californicum*), and *canescens* in rabbitbrush (*Chrysothamnus*) and saltbush. Clutch 3–5 eggs, usually 4, whitish to pale blue and spotted with brown, rusty brown or black; incubation by female only, period 10–16 day; chicks fed by both parents, nestling period 9–10 days. Sometimes parasitized by Brown-headed Cowbird (*Molothrus ater*), which may cause nest abandonment.
Movements. Far N populations of nominate race migratory; insular populations resident. Some nominate birds breeding in C California migrate downslope and S in winter, during which time *canescens* (from interior) and nominate (from coast) can be found together in same habitat. Race *canescens* moves upslope in summer after breeding, and in autumn descends and proceeds to move S to wintering areas. Some move down into lower desert, or to lower Colorado Valley.
Status and Conservation. Not globally threatened. Classified as "Declining" in the USA (Yellow WatchList priority species for conservation). San Clemente race *clementeae* protected under the Endangered Species Act in the USA since 1977. Fairly common to locally common. Formerly common on San Clemente I, but introduced goats (*Capra*), pigs (*Sus*), cats (*Felis*) and rats (*Rattus*) have decimated local populations; removal of feral animals and restoration of natural habitat recommended.

Akcakaya *et al.* (2005), Beadle & Rising (2002), Bent & Austin (1968), Cicero & Johnson (2006, 2007), Ellison (1999), Everett *et al.* (1994), Grinnell (1915), Hellmayr (1938), Howell & Webb (1995), Iliff (2003), Johnson & Marten (1992), Klicka & Banks (2011), Lebbin *et al.* (2010), Martin & Carlson (1998), Miller *et al.* (1957), Misenhelter & Rotenberry (2000), Patten & Unitt (2002), Pyle (1997), Ridgway (1901), Rising & Beadle (1996), van Rossem (1932), Russell & Monson (1998), Sullivan *et al.* (2005), Willey (1990, 1997), Wolf (1977).

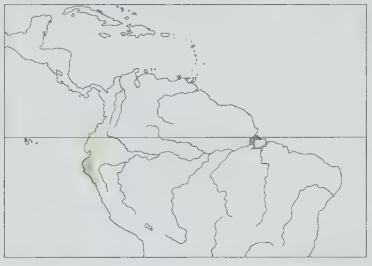
91. Sage Sparrow

Artemisiospiza nevadensis

French: Bruant des armoises **German**: Salbeiammer **Spanish**: Chingolo de Nevada

Taxonomy. *Poospiza belli nevadensis* Ridgway, 1874, West Humboldt Mountains, Nevada, USA.
Until recently placed in genus *Amphispiza*, and considered conspecific with *A. belli*, but recent molecular work indicates that the two are, instead, members of a well-resolved clade of "grassland" sparrows that includes genera *Pooecetes*, *Oriturus*, *Passerculus*, *Ammodramus* (in part), *Melospiza* and *Xenospiza*. Present genus newly erected to accommodate these two species. Range meets that of *A. belli* of race *canescens*, which is closely similar in appearance to present species, and the two may hybridize; further research required. N birds sometimes separated as race *campicola* but differences slight and perhaps clinal. Monotypic.
Distribution. Breeds in Great Basin of W USA from E Washington and S Wyoming S to CE California, SE Nevada, NE Arizona and N New Mexico. Non-breeding C California E to SW Utah and C New Mexico, S to N Mexico (N Baja California, N Sonora and N Chihuahua) and W Texas.

Descriptive notes. 14–18 cm; 15·3–21·9 g. A medium-sized sparrow, with long tail often held cocked. Has greyish head, crown faintly streaked, white supraloral spot and eyering, dark lores, grey ear-coverts; broad white submoustachial stripe, indistinct narrow dark grey malar stripe (often broken, sometimes absent); upperparts sandy brown, moderately distinct blackish streaking on mantle and back, rump plain brown; tail dark brown, outer web and tip of outer rectrices white (in unworn plumage); upperwing brown, feathers narrowly edged lighter brown, median and greater coverts also with whitish-buff tips (forming two diffuse wingbars); throat white; underparts buffy white, conspicuous dark brown central breast spot, breast and flanks lightly streaked, belly dull white; iris dark brown; bill dark grey, sometimes paler on lower mandible; legs dark brownish, feet greyer and duskier. Differs from *A. belli* mainly in larger size, paler coloration, more obvious streaking above. Sexes alike in coloration. Juvenile is brownish above, paler and with buffish wash below, with streaked crown, upperparts and breast and flanks, pale brown superciliary stripe broken at centre. Voice. Song a weak, plaintive, high-pitched series of tinkling notes. Alarm call a short, bell-like "tsip".
Habitat. In breeding season found in big sagebrush (*Artemisia tridentata*) or sagebrush–saltbush (*Artemisia–Atriplex*); at higher elevations may be found in sagebrush interspersed with scattered junipers (*Juniperus*) or pinyon (*Pinus* cf. *edulis*). In SE California in winter commonly in weedy scrub (especially *Suaeda*), often near water. On migration may be found in creosote bush (*Larrea*), rabbitbrush (*Chrysothamnus*) and greasewood (*Sarcobatus vermiculatus*). Sea-level to nearly 2500 m.
Food and Feeding. Variety of animal and plant items. Generally eats a variety of seeds and other vegetable matter. Probably eats animal food in winter when available. Young fed with insect food. Arthropods taken include grasshoppers (Orthoptera), chinch bugs (Hemiptera), nymphal and adult leafhoppers (Homoptera), beetles (Coleoptera), ants (Formicidae) and other Hymenoptera, and lepidopteran caterpillars, as well as spiders (Araneae). Forages principally on or near ground; typically, runs on the ground, from bush to bush, with tail held cocked. Also gleans insects low in vegetation. Sometimes in small groups outside breeding season.
Breeding. Season Mar–Jul; may be double-brooded, but later broods possibly replacement clutches. Monogamous. Quite unusually, often already paired when arriving on breeding grounds. Nest built by female, taking 1–2 days, a cup of coarse grasses, lining with finer grasses, wool, feathers and hair, placed in depression in ground or, more commonly, low (10–100 cm above ground) in bush, most commonly big sagebrush, sometimes bitterbrush (*Purshia*), rabbitbrush, greasewood, tumbleweed (*Salsola iberica*) or bunchgrass. Clutch 3–5 eggs, usually 4, whitish to pale blue and spotted with brown, rusty brown or black; incubation by female, period 10–16 days; chicks fed by both parents, nestling period 9–10 days. Nests sometimes parasitized by Brown-headed Cowbird (*Molothrus ater*), which may cause nest abandonment.
Movements. Migratory, withdrawing from most of breeding range; some S populations possibly resident. Arrival on breeding grounds mid-Mar to late Apr, later in N breeding areas than in S; arrives already in pairs, suggesting that partners may migrate together. Peak of autumn migration in mid-Sept, passage continuing through mid-Nov. Casual in winter N to Oregon, possibly to SW Canada (from SW British Columbia), and E to W Montana, W Kansas and W Oklahoma, apparently also Nova Scotia (Briar I).
Status and Conservation. Not globally threatened. Probably not uncommon; status difficult to determine, as species often difficult to see. May be common in optimum habitat. Sensitive to changes in habitat, especially conversion of sagebrush terrain to grassland.
Bibliography. Beadle & Rising (2002), Bent & Austin (1968), Best & Petersen (1982, 1985), Cicero & Johnson (2006, 2007), Forsythe (1995), Grinnell (1915), Gustafson (1975), Hellmayr (1938), Howell & Webb (1995), Johnson & Marten (1992), Klicka & Banks (2011), Martin & Carlson (1998), Meents *et al.* (1982), Miller *et al.* (1957), Moldenhauer (1970a, 1970b), Patten & Unitt (2002), Petersen & Best (1985b, 1986, 1987), Petersen *et al.* (1986), Pyle (1997), Reynolds (1981), Rich (1978, 1980a, 1980b, 1981, 1983a, 1983b, 1985a, 1985b), Ridgway (1901), Rising & Beadle (1996), Shackford (1989), Wiens (1982), Wiens *et al.* (1990), Winter & Best (1985).



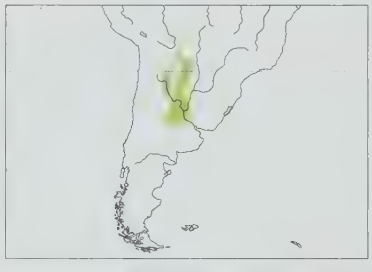
Genus *RHYNCHOSPIZA* Ridgway, 1898

92. Tumbes Sparrow

Rhynchospiza stolzmanni

French: Bruant de Tumbes **German**: Stolzmannammer **Spanish**: Chingolo de Tumbes

Taxonomy. *Haemophila stolzmanni* Taczanowski, 1877, Tumbes, Peru.
Genus formerly subsumed into *Aimophila*; recent molecular studies, however, indicate that present species and *R. strigiceps* are close relatives of each other, and only distantly related to other species currently included in *Aimophila*. Monotypic.
Distribution. Tumbesian region of SW Ecuador (W Loja) S to NW Peru (from Tumbes S to N La Libertad).



Descriptive notes. 14·5 cm; 23·7–27·6 g. A short-tailed sparrow with thick-based conical bill, striped crown and streaked back; feet relatively large. Has grey central crownstripe, cinnamon-brown lateral crownstripe, grey face with brown eyeline, grey supercilium with paler, whitish, supraloral area, broken white eyering, short brown stripe below eye (beginning at gape), short blackish moustachial stripe, whitish submoustachial area, and narrow blackish malar line; upperparts dull brown with darker streaks; tail feathers very dark brown with greyish edges; upperwing brownish, rusty shoulder patch created by rusty lesser upperwing-coverts, with median and greater upperwing-coverts fringed grey-buff, primaries with whitish-buff edges, secondaries with cinnamon edges, tertials fringed pale buff, marginal coverts yellow (creating yellow area at bend of wing on perched bird); off-white below, with clean white throat, slightly greyer on breast, pale buff flanks; iris dark; upper mandible black, lower mandible and tip blue-grey to dull orange; legs pinkish. Sexes similar. Juvenile is similar to adult, but duller and more muted in coloration, and finely streaked on breast. Voice. Song variable, in two or three parts, some rather mechanical and others much more fluid and sweet, e.g. "toosoo-toosoo" and "tuswee'chi'i'i'i'i". Call a metallic "tink", sometimes several in close succession.
Habitat. Arid scrub, and semi-desert with cacti, bushes, as well as open dry forest, and riparian scrub; partial to locations with nearby water. In particular, prefers at least sparse grass cover nearby or adjacent to desert scrub. To 1000 m.
Food and Feeding. Diet insects and seeds; large and deep bill suggests ability to take relatively large seeds. Forages terrestrially; singly and in pairs, not in flocks.
Breeding. Breeds in wet season, Jan–May. Nest a cup of grass, lined with finer vegetation and down, positioned on ground in a grassy patch, often close to shrub or tree. Clutch 4 eggs, pale whitish-blue or white. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tumbesian Region EBA. Common to fairly common throughout its small range.
Bibliography. Armani (1985), Byers, Curson & Olsson (1995), DaCosta *et al.* (2009), Paynter (1967), Ridgely & Greenfield (2001a), Ridgely & Tudor (1989), Schulenberg *et al.* (2007), Williams (1981b).

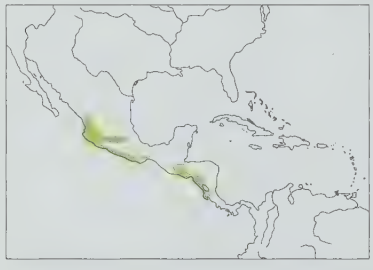
93. **Stripe-capped Sparrow**

Rhynchospiza strigiceps

French: Bruant à calotte rayée **Spanish**: Chingolo Coronicastaño
German: Streifenscheitelammer

Taxonomy. *Zonotrichia strigiceps* Gould, 1839, Santa Fe, Argentina.
Genus formerly subsumed into *Aimophila*; recent molecular studies, however, indicate that present species and *R. stolzmanni* are close relatives of each other, and only distantly related to other species currently included in *Aimophila*. Two subspecies recognized.
Subspecies and Distribution.
A. s. dabbenei (Hellmayr, 1912) – SE Bolivia S to NW Argentina (Jujuy, Salta and Tucumán).
A. s. strigiceps (Gould, 1839) – SC Paraguay S to NC Argentina (to Córdoba and N Buenos Aires).

Descriptive notes. 15–16 cm; 20·5–23·7 g. A long-tailed, short-winged sparrow with medium-sized conical bill, striped crown and streaked back. Nominate race has grey central crownstripe, cinnamon-brown lateral crownstripe, grey face with cinnamon-brown postocular stripe, black preocular stripe and paler supraloral area; narrow black moustachial stripe sometimes mixed with cinnamon-brown, black malar stripe; upperparts pale brown with darker streaks; tail feathers dark brown with light buff edges; upperwing brownish, warmer shoulder patch created by warm brown lesser upperwing-coverts, with median and greater coverts fringed grey-brown, primaries with whitish-buff edges, secondaries with cinnamon edges, tertials edged rusty; off-white below, with clean white throat, narrow blackish lateral throat-stripes and whitish malar area; diffuse greyish breastband, buff flanks; iris dark; upper mandible black, lower mandible mainly ivory-coloured; legs pinkish. Sexes similar. Juvenile is similar to adult, but duller and more muted in coloration, and finely streaked on breast. Race *dabbenei* is larger and darker than nominate, darker face pattern including extensive black on lores and around bill base, darker crownstripes, and darker rufous edging on wing-coverts and tertials. Voice. Song far-carrying, strident and sweet. Males have diverse repertoire of song types, and will sing one many times before switching to next. In general songs are in two or three parts: two-part songs begin with stuttering series of strident notes followed by slow trill, "teet teet teet teet twreeeeeeeee", different types varying in length and pitch of trill, as well as in quality of introductory notes; three-part songs similar, but introduced by 2 or 3 soft notes before louder part begins. Call a metallic "tweep".
Habitat. Open and dry sites with a shrub component, including shorter and more open *chaco* woodlands, to agricultural areas where dry scrub and shrub left at edges; also requires a certain amount of grass in territory, usually beneath taller shrub layer. To 1000 m.
Food and Feeding. Diet both seeds and insects; provisions young entirely with insects. Forages on ground. Usually seen alone, but sometimes forages in pairs; in non-breeding season may form small loose flocks.
Breeding. Season Oct–Mar, slightly later in NW Argentina than in C Argentina. Nest a well-formed cup of dry grasses, lined with finer material, placed at base of bush or beneath taller and denser stand of grass. Clutch 3–4 eggs, pale blue. Nests occasionally parasitized by Shiny Cowbird (*Molothrus bonariensis*). No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Common throughout its range. Present in several protected areas in Argentina.
Bibliography. Armani (1985), Byers, Curson & Olsson (1995), Canevari *et al.* (1991), DaCosta *et al.* (2009), Hoy (1971), Kratter *et al.* (1993), Ridgely & Tudor (1989), Short (1976).



Genus *PEUCAEA* Audubon, 1839

94. **Stripe-headed Sparrow**

Peucaea ruficauda

French: Bruant ligné **German**: Rostschwanzammer **Spanish**: Chingolo Cabecilistado
Other common names: Russet-tailed Sparrow

Taxonomy. *Chondestes ruficauda* Bonaparte, 1853, Nicaragua.
Formerly placed in *Aimophila*, but molecular-genetic studies indicate that such treatment would make that genus polyphyletic. Various studies suggest that this species is part of a group that includes also *P. humeralis*, *P. mystacalis*, *P. sumichrasti* and *P. carpalis*, this group being sister to a clade containing *P. cassinii*, *P. aestivalis* and *P. botterii*. Proposed race *ibarrorum* (described from La Avellana, in Guatemalan Southern Pacific lowlands) included within *ruficauda*. Four subspecies recognized.
Subspecies and Distribution.
P. r. acuminata (Salvin & Godman, 1886) – Pacific slope of Mexico from S Durango and S Zacatecas S to SE Guerrero, E to Morelos and S Puebla.
P. r. lawrencii (Salvin & Godman, 1886) – S side of Isthmus of Tehuantepec in Oaxaca and extreme W Chiapas, in S Mexico.
P. r. connectens (Griscom, 1930) – valley of R Motagua, in E Guatemala.
P. r. ruficauda (Bonaparte, 1853) – Pacific slope from SE Guatemala S to NW Costa Rica.

Descriptive notes. 15–19·5 cm; 25·4–30·4 g (*acuminata*), 31·5–44·7 g (*lawrencii*). Medium-sized to fairly large sparrow, larger in S than in N. Nominate race has crown and side of face blackish-brown, pale spot on rear ear-coverts, white median crownstripe, broad white supercilium; upperparts mainly rufous-brown, streaked blackish, rump and uppertail-coverts brown to cinnamon brown with obscure darker streaks; tail rufous; upperwing blackish-brown, feathers narrowly edged pale buff, edges of secondaries rufous, median and greater coverts and tertials with broader rufous edges and pale buff tips; throat white; breast and upper flanks pale grey, indistinct necklace of greyish splotches, belly whitish, lower flanks and undertail-coverts washed cinnamon; iris deep brownish-red; upper mandible blackish, lower mandible mostly pale bluish-grey to ivory-coloured; legs pale pinkish. Sexes similar. Juvenile is like adult, but black areas brownish, throat speckled with dusky, belly duskier than adult. Races differ in size and plumage: *lawrencii* is larger than nominate, dark areas of head browner, upperparts greyer-looking, less rufous, tail duller; *connectens* is intermediate between previous and nominate; *acuminata* is much smaller than others, dark areas of head blacker, no pale spot on ear-coverts, upperparts paler and browner, less rufous, underparts paler. Voice. Song a continuous jumble of high squeaky notes, perhaps accelerated with excitement; mates greet with chattering duet. Call a nasal "chuh".
Habitat. Xeric grasslands with scattered trees dominated by legumes; on rocky slopes, brushy fence rows and edges of fields; locally in overgrazed fields dominated by flat-pad cactus (*Platyopuntia*); also disturbed roadsides. Sea-level to 1400 m.
Food and Feeding. Principally seeds, small insects, spiders (Araneae), and fruits; feeds young with insects. Usually forages on ground, but also low in vegetation. At all seasons found in groups of generally 3–7 individuals, occasionally more.
Breeding. Season Apr–Nov, sometimes later on coast than inland; probably double-brooded. Cooperative breeder, up to seven individuals attend nest. Nest a deep cup made from dry grasses and twigs, lined with finer grasses and hair, placed 0·3–1·5 m above ground and usually in dense and spiny bush. Clutch 2–4 eggs, pale blue. No information on incubation and nestling periods.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Fairly common to common; often common or very common in appropriate habitat. Somewhat more local in interior.
Bibliography. Anon. (1998), Armani (1985), Binford (1989), Davis, J. (1953, 1960a), Griscom (1932), Howell & Webb (1995), Rowley (1962, 1984), Selander & Giller (1959), Stiles & Skutch (1989), Storer (1955), Webster (1959a), Wolf (1977).

95. **Black-chested Sparrow**

Peucaea humeralis

French: Bruant à plastron **German**: Schwarzbrustammer **Spanish**: Chingolo Pechinegro

Taxonomy. *Haemophila humeralis* Cabanis, 1851, Tehotepec, Puebla, Mexico.
Formerly placed in *Aimophila*, but molecular-genetic studies indicate that such treatment would make that genus polyphyletic. Various studies suggest that this species is part of a group that includes also *P. ruficauda*, *P. mystacalis*, *P. sumichrasti* and *P. carpalis*, this group being sister to a clade containing *P. cassinii*, *P. aestivalis* and *P. botterii*. Birds of N Colima have sometimes been separated as race *asticta*, but doubtfully valid. Monotypic.
Distribution. WC & SC Mexico from S Jalisco and Colima E to Morelos and Puebla, S to Guerrero and SW Oaxaca.
Descriptive notes. 15–15·5 cm; 18–27·6 g. A medium-sized sparrow. Has head blackish, white loral spot and moustachial stripe; white throat bordered by thin black malar stripe and black chestband (in fresh plumage, black areas, including on head, partly obscured by pale rufous feather fringes); upperparts rufous, mottled darker brown, becoming olive-brown on rump and uppertail-coverts; tail and upperwing blackish-brown, feathers edged paler brown, two whitish wingbars; underparts whitish, flanks and undertail-coverts washed with cinnamon; iris brown; upper mandible black, lower mandible blue-grey; legs pale pinkish. Sexes similar. Juvenile is duller than adult, with grey-

ish head and chestband, rufous-streaked crown. Voice. Song, sometimes in duet, typically a high liquid twittering preceded by one to a few short introductory notes, "bzz, bzz, bzz, t-chip ichip tip-i-see"; also has chatter-song, lasting 1·5–2 seconds, or a soft "whisper song". Call "pit-za"; also "chip", sometimes followed by trill, also a thin "tzeet".
Habitat. Arid tropical scrub-forest and thorn-forest with trees 11–32 m tall and with continuous canopy of varying heights; at 300–1500 m.
Food and Feeding. Little information on diet; in breeding season, at least, mainly animal items, especially insects, such as lepidopteran larvae, grasshoppers (Orthoptera), termite (Isoptera) workers, also some seeds and fruit. Usually feeds in canopy, where it catches insects often by foliage-gleaning in manner of a vireo (Vireonidae) or by hover-picking. Generally forages singly or in pairs; larger groups unusual, and probably family parties.
Breeding. Season May–Sept; probably double-brooded, and perhaps multi-brooded. Apparently monogamous, and generally seen in pairs. Nest made from dry grasses and twigs, lined with fine grasses and cattle hair, often with canopy of dry grass constructed over it, placed on or near ground in thick cover. Eggs whitish-blue with dark spots. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Balsas Region and Interior Oaxaca EBA. Often common or very common in appropriate habitat.
Bibliography. Anon. (1998), Armani (1985), Binford (1989), Hellmayr (1938), Howell & Webb (1995), Rowley (1962), Storer (1955), Wolf (1977).

96. Bridled Sparrow

Peucaea mystacalis

French: Bruant à moustaches **German**: Zügelammer **Spanish**: Chingolo Embridado

Taxonomy. *Zonotrichia mystacalis* Hartlaub, 1852, Río Frío, between Puebla and Mexico City, Mexico.
Formerly placed in *Aimophila*, but molecular-genetic studies indicate that such treatment would make that genus polyphyletic. Various studies suggest that this species is part of a group that includes also *P. ruficauda*, *P. humeralis*, *P. sumichrasti* and *P. carpalis*, this group being sister to a clade containing *P. cassinii*, *P. aestivalis* and *P. botterii*. Monotypic.
Distribution. S edge of C plateau of Mexico in E México, S Puebla, CW Veracruz and N & C Oaxaca.

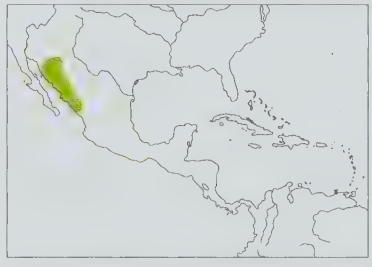
Descriptive notes. 15–16·5 cm; 19·3–25·9 g. A medium-sized sparrow. Has crown and nape grey, faintly streaked darker, side of face grey, white supraloral stripe, broken eyering and submoustachial stripe enclosing black loral area and area beneath eye, throat black; upperparts brown with broad blackish streaks, scapulars, rump plain rusty fading to dull brown on uppertail-coverts; tail feathers blackish with thin grey edges; upperwing greyish-brown with pale feather edges, median and greater coverts also with broad whitish tips (forming two whitish wingbars); breast and side of neck grey, belly white, becoming rufous-buff posteriorly and on undertail-coverts; iris brown; upper mandible black, lower mandible pale blue-grey to pale pinkish; legs flesh-coloured. Sexes similar. Juvenile is like adult, but duller, grey above, mottled darker grey, with pale supercilium and throat, breast greyish-white with thin, broken grey streaks. Voice. Song a series of slightly sneezy, sharp and sweet chipping notes, becoming an excited liquid chatter, e.g. "w-sik, w-sik w-sik, w-sik w-sik...w-syu w-syu"; duetting occurs. Call a sharp liquid "check", "tzeet" or "tut".
Habitat. Semi-open arid tropical scrub, thickets and grassy clearings, and open leguminous thorn-forest interspersed with large cacti; in Oaxaca found in scrubby oaks (*Quercus*) and in clearings in early successional thorn-scrub. At 900–1800 m.
Food and Feeding. Little information on diet; eats seeds, small insects (orthopterans), spiders (Araneae), and fruits. Forages principally near ground or low in vegetation, or on ground; at times may hover-glean. Often in pairs; forms foraging flocks during non-breeding season.
Breeding. Season May–Jul; double-brooded. Monogamous. Nest a cup of dry grass and twigs, lined with finer grasses and hair, placed close to or on ground, sometimes below cactus, or low in shrub. Clutch 3–4 eggs, whitish-blue. No other information.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Balsas Region and Interior Oaxaca EBA. Often common or very common in appropriate habitat.
Bibliography. Anon. (1998), Armani (1985), Binford (1989), Hellmayr (1938), Howell & Webb (1995), Palacios-Silva *et al.* (2005), Storer (1955), Wolf (1977).

97. Cinnamon-tailed Sparrow

Peucaea sumichrasti

French: Bruant à queue rousse **German**: Zimtschwanzammer **Spanish**: Chingolo Colicanela
Other common names: Sumichrast's Sparrow

Taxonomy. *Haemophila sumichrasti* Lawrence, 1871, Juchitán, Tehuantepec, Oaxaca, Mexico.
Formerly placed in *Aimophila*, but molecular-genetic studies indicate that such treatment would make that genus polyphyletic. Various studies suggest that this species is part of a group that includes also *P. ruficauda*, *P. humeralis*, *P. mystacalis* and *P. carpalis*, this group being sister to a clade containing *P. cassinii*, *P. aestivalis* and *P. botterii*. Monotypic.
Distribution. Pacific slope of SE Oaxaca and extreme SW Chiapas, in S Mexico.
Descriptive notes. 14·5–16·5 cm; 23·1–30·1 g. A fairly large sparrow. Has rufous crown with narrow darker streaks, grey median crownstripe, pale grey supercilium paler anteriorly, blackish preocular stripe, rufous postocular stripe extending to and curving down around rear ear-coverts;



ear-coverts greyish, area below eye whitish, short black moustachial stripe sometimes with some rufous admixed, whitish submoustachial stripe, thin black malar stripe, white chin and upper throat; upperparts greyish-buff with rufous-edged broad blackish streaks, rump to tail rufous, uppertail-coverts and tail feathers with narrow buff edges; upperwing mostly blackish-brown with pale feather edgings, lesser coverts rufous, median and greater coverts and tertials with broader edges and whitish tips (forming two indistinct wingbars); throat white, breast pale grey with faint buffy wash, belly whitish, flanks and undertail-coverts washed light cinnamon-buff; iris deep brown; upper mandible usually dark horn-brown to greyish, lower mandible pinkish-flesh; legs horn-colour or pink. Sexes similar in coloration. Juvenile resembles adult, but duller and less distinctly marked above, more yellowish-buff below, with dusky streaks on breast. Voice. Song a sprightly tinkling series of chipping notes, sometimes whistle-like, often with 1–5 introductory notes, e.g. "bzz, bzz, bzz, t-chip ichip tip-i-see"; sometimes a soft whisper song, by two birds close together; sometimes sings in duet. Call "tee, tee, tee", or shortened to a simple "tzee".
Habitat. Slightly open areas in arid tropical scrub (with *Jatropha* and *Ipomoea*) up to 6 m tall, also thickets and grassy clearings; apparently favours more wooded habitats than those preferred by *P. ruficauda*. Sea-level to 900 m.
Food and Feeding. Little information on diet; probably seeds, small insects, spiders (Araneae) and fruits. Sometimes takes nectar. Apparently eats principally animal matter when feeding young. Forages principally on or near ground or low in vegetation. Often in pairs or small groups.
Breeding. Egg-laying from early Jun to early Sept, and bird in breeding condition on 22nd May in Oaxaca; double-brooded. Nest not described; probably placed near ground. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Isthmus of Tehuantepec EBA. Locally fairly common to common. Estimated total population fewer than 50,000 individuals. Has very small global range, and is possibly suffering from habitat degradation. Population thought to be stable, but little information. Habitat fragmented following construction of Pan-American Highway; also, many forest areas now degraded. Research required to assess impact of potential threats.
Bibliography. Amadon & Eckelberry (1955), Anon. (1998, 2010c), Armani (1985), Binford (1989), Butchart & Stattersfield (2004), Hellmayr (1938), Howell & Webb (1995), Miller *et al.* (1957), Stattersfield & Capper (2000), Wolf (1977).

98. Rufous-winged Sparrow

Peucaea carpalis

French: Bruant à épaulettes **German**: Rostflügelammer **Spanish**: Chingolo Alirrufo

Taxonomy. *Peucaea carpalis* Coues, 1873, Tucson, Arizona, USA.
Formerly placed in *Aimophila*, but molecular-genetic studies indicate that such treatment would make that genus polyphyletic. Various studies suggest that this species is part of a group that includes also *P. ruficauda*, *P. humeralis*, *P. mystacalis* and *P. sumichrasti*, this group being sister to a clade containing *P. cassinii*, *P. aestivalis* and *P. botterii*. Geographical variation largely clinal, and races weakly differentiated; *bangsi* intergrades with nominate in NC Sonora and with *cohaerens* in N Sinaloa, and sometimes considered to be inseparable from latter. When species treated in same genus as *Amphispiza bilineata* (e.g. both placed in *Aimophila*), race *bangsi* of latter has priority; in such a case, race *bangsi* of present species assumes replacement name *distinguenda*. Three subspecies tentatively recognized.
Subspecies and Distribution.
P. c. carpalis Coues, 1873 – extreme S USA (SC Arizona) and adjacent NW Mexico (S to C Sonora).
P. c. bangsi (R. T. Moore, 1932) – NW Mexico (NC Sonora S to N Sinaloa).
P. c. cohaerens (R. T. Moore, 1946) – N & C Sinaloa.

Descriptive notes. 13·5–14·5 cm; 12·6–17·5 g. A small, rather slim sparrow. Nominate race has crown and nape rufous, grey median crownstripe, broad grey supercilium, grey side of head with rusty postocular stripe, black preocular stripe; short, thin blackish moustachial stripe and malar stripe separated by pale greyish submoustachial area; upperparts buffy grey, mantle and scapulars with rusty-edged dark brown streaks, rump paler; tail feathers dark grey-brown with narrow paler edges; upperwing dark brown, lesser coverts rufous, median and greater coverts broadly edged buffish and with buff-white tips (forming two indistinct wingbars), flight-feathers narrowly edged greyish-buff, tertials with broader pale edges; throat whitish, side of neck and underparts pale grey, becoming paler on belly, flanks washed pale buff; iris deep brown; bill yellowish to pinkish-flesh, usually with extensive dusky-horn on upper mandible; legs pinkish or yellowish-flesh to brownish. Sexes similar. Juvenile is similar to adult, but more buff overall, with rufous areas more dark brown, breast and flanks with prominent dark streaks. Races differ in size and in plumage darkness, nominate largest and greyest above: *cohaerens* is smallest and darkest, with rufous cast on rump and back; *bangsi* is intermediate in size between previous and nominate, slightly browner above than nominate. Voice. Song a plaintive rapid series of whistled notes, often with 1–3 introductory notes, e.g. "chip burr chip-ip-ip-ip-ip-ip-ip", first note(s) higher than following trill (or sometimes on same pitch, or lower); also a "chip chip whecoo". Call a distinctive high-pitched "seep", also "chink".
Habitat. Desert scrub (Arizona and Sonora) and tropical thorn-scrub (Sinaloa), with mixed bunchgrass, and in open farmland in tropical deciduous forest, especially mesquite (*Prosopis*), but also hackberry (*Celtis*) and acacia (*Acacia*) with cholla cactus (*Opuntia*). Present from sea-level up to 1200 m.
Food and Feeding. Diet consists of grass and weed seeds, and arthropods. In winter, mostly seeds (e.g. of *Aristida*, *Panicum*, *Paspalum*); in summer, mostly animal items, typically insects, especially inchworms (Geometridae) and other caterpillars, and also some spiders (Araneae). Forages principally on or near ground and low in vegetation. Often in pairs or small groups.
